171, FLEET STREET.

TO OUR READERS.

THERE are periods when "we would not if we could be gay," and this is one of them. We have had to assort the letters accumulated during many years; and as they were perused and placed aside, the picture seemed realised of the old soldier returned to his boyhood's home, and, as he stood within its open door, the admitted breeze

> "Caught the old dangling almanacks behind,
> And up they flew like banners in the wind;
> Then gently, singly—down—down—down they went,
> And told of twenty years irrevocably spent."

Each almanack in that series recalled events—some craped, some golden—and so was it with our letters of years gone by. Many from friends now busied with life's sterner employments; others from those who have adopted "a home across the waters;" and not a few from Beaton, and Errington, and Chitty, and Payne, and others whose life's work is finished.

Now, though we would not be gay, yet we have yielded to this train of thought, because we can add a record of those characteristics of life—merciful compensations. Many pens that enriched our earliest numbers still add value to those now current. Many pens that once were active for us in "the old country" still afford us aid—novel aid—from Canada, Australia, New Zealand, and even the Isles of the Pacific; and still more numerous year by year are the fresh pens ably employed to add value to our columns.

When we laid down the last of the accumulated letters of bygone years we observed, "What kindly feeling pervades them all!" That sentence is now endorsed on each bundle; and when at the end of future years we have to assort a fresh accumulation of letters, we have no fear that the same sentence will not be appropriate, for all continue to be like spirited to those from which we give these two extracts:—

"*Canada West.*—Your kind and genial letter gladdened the heart of myself and wife more than anything in the epistolary line ever received by us. Its thoroughly English tone and fraternal good wishes were particularly enjoyable, and, withal, very seasonable; for on the day of its receipt I was rather downhearted after discovering the fearful havoc made by those pests, field mice, among our young trees. We should be indeed dull without the weekly gleams of sunshine brought by "our Journal;" but the additional warmth produced by your note will long be maintained.

"I trust that before long we may have the pleasure of shaking hands personally, although now we can do so across the water. The idea, too, that my little scrawl will please "WILTSHIRE RECTOR" will, in our eyes, give increased value to his ever-welcome contributions. On the day of the arrival of your letter another inspiriting event occurred in our establishment. Some days previously, while in the bush, as it is here termed, I discovered under the snow a small Hepatica, which I *chopped* out of its frozen surroundings and brought into the house, and after thawing it out, potted it. On the day above named it opened the first blossom, and I can assure you it is as highly prized as the first Orchid in a great establishment."

The other extract, from a letter signed "A POOR WORKING MAN," is as follows:—

"The kindest thanks of myself and all my fellow working men are due to all those who have kindly interested themselves in promoting, by their writings in your Journal, the instruction and comfort of the working man. All honour to the noble band. May they live to write, and see the fruits of their labours in the improved condition, both moral and social, of the poor and often neglected sons and daughters of toil."

Every reader will join with us in chorusing that gratifying, cheering wish. We retain the aid of that "noble band;" therefore we renew our advance cheerily. Yet there must occur some oversights, so for our future volumes we will employ the words of the old herbalist Gerarde —"Accept them, loving countreymen, as tokens of our good will; and we trust that the best and well-minded wil not rashly condemne us, although some things have passed worthy reprehension."

INDEX.

Acacias, Farnesiana, 53; platyptera after blooming, 109; soil for, 169
Accrington Poultry Show, 270
Achimenes—and Tydæa, 53; culture, 110; growing specimen, 184; list of, 348; liquid manure for, 453
Acrophyllum venosum culture, 452
Agave schidigera, 360
Agricultural (Royal), Society's Poultry Show, 1-2, 309; Show at Bury, 349
Allamanda starting, 54
Aloysia citriodora cuttings, 381
Alston Poultry Show, 37
Alum-crystallised flowers, 429
Alyssum, Sweet, for edging, 152
Amaranthus melancholicus ruber culture, 414
Amaryllis Adonis, 54; pardina, 410
Amateurs and gentlemen's gardeners at exhibitions, 127
Anemones, taking up, 332
Angelica culture, 168
Angræcum citratum, 163
Annuals—for bedding, 152; for ornament and bouquets, 102; ornamental-foliaged, 134; for pots, 163; for late blooming, 218; culture of early, 451
Anthurium Scherzerianum culture, 168
Ants—driving away, 199, 315; exterminating, 333, 432; expelling, 397
Aphides, destroying in the open air, 333
Apples—for North of Ireland, 109; branches sawn off, 111; pruning pyramidal trees, 251; crop of 1867, 372
Apricot—v. Peach treatment, 74; profusely set, 276
April, hardy plants flowering, 407
Aquilegia pyrenaica, 28
Arabis—variegata, propagating, 398; lucida variegata for edging, 432
Artemisia annua, 348
Arts and Sciences, Hall of, 312
Ash, grafting a Weeping, 199
Asparagus—beds, saving, 218; making, 252, 301; planting, 252; culture, 282, 314; blight, 347; couch grass in beds, 348; a bundle of, 380; fasciated, 380
Aspect of greenhouse, 238
Asphalt walks, 266
Asphalting v. gravelling, 104
Asphodelus culture, 74
Aster, Cape, culture, 364
Aucuba—berries poisonous? 45; Standish's hermaphrodite, 71; pollen of, 233; flowers, fertilising, 301; cuttings, 316; raising from seed, 381
Auricula seedlings, pricking out, 332
Aviary—removing paint from, 116; birds for, 140; birds in, 272
Ayr Poultry Show, 235
Azaleas—forcing, and culture, 13; Her Majesty, 23; soil for, 54; management, 74; leaves falling, 109; list of, 119; potting, 167; not flowering, 218, 253; propagating, 267; cuttings, 452

Bacon, Wiltshire mode of curing, 20
Badminton Poultry Show, 434
Balm, propagating Golden, 453
Balsams for July, 94
Bantams—with Cochin-Chinas, 20; dubbing Game, 80, 420; Sebright, 234; pencilled, 318; story of the Black, 361; chickens, food for, 438
Bark-bed, fungus in, 413
Barkston Head, 9
Barleria Gibsoni, 163
Basket plants, hardy, 300
Bath and West of England Poultry Show, 417; doings at, 434
Beans, protecting, 125
Bedding plants—new variegated, 153; from seed, 169; exhibiting collections of, 249; for a north aspect, 252; blue flowered, 322; blue, 376
Bedding-out, rules for, 397
Bees—hive overturned, 19; swarms deserting, royal cell sealed, 20; Egyptian, foul brood, 39; Woodbury hives, 40; brood remaining undeveloped, supply of water important, limiting drones, shifting hives, 60; American Bee-keepers' Institute, shifting stock hives, 79; maggots in combs, breeding in supers, storing combs, 80; swarms clustering, variation in hybrids, hiving in moveable comb hive, breeding in supers, starvation amid plenty, Ligurian queens, 98; Woodbury hives, 115; clustering, moving hives, total mortality, 116; an unlucky apiary, pollen-gathering at Christmas, 139; food of queens, importance in the economy of nature, foul brood in a purchased stock, boxes for hives, woodentopped straw hives, 140; foul brood, 155; boxes for hives, feeding in spring, 156; transformation of comb, removing old comb, 171; Pettitt's new hive, gloves, 172; hybridisation, plurality of queens, 187; tomtits, "Management of," decayed stock, greatest apiary, 198; fumigating, keeping in Devon, 202; driven, foul brood, aspect of apiary, 203; desertion of hives, condemned and saved, hives, artificial swarms, 204; breeding in supers, young, successful driving, gloves, employing empty combs, Woodbury's unicomb hive, 220; foul brood, queenless, unfertile queens, 239; distance of drones' influence, breeding in supers, 249; advantages of frame hives, hybridisation, 255; hives, situation of, entrance to Nutt's collateral, 256; Bagster's melting honeycombs, 270; propagating Ligurians, 271; preventing swarming, flowers for, artificial swarms, production of queens, ventilating, 272; plurality of queens in a hive, 287; how to empty honeycombs, non-resisting, propagating Ligurian, Payne's hives, 288; in Russia, 302, 401; frame hives, feeding, range of flight, 304; Ligurians in Ireland, drone-brood, 319; honey candying in combs, 320; mistaking their hives, 335; mead or metheglin, preventing loss of swarms; Ligurians in Ireland, obtaining artificial swarms, 336; hybridisation, 351; obtaining artificial swarms, preventing second swarms, 352; non-resisting, 367; "Why did ye die?" comb-emptying machine, not working in a super, destroying drones and drone-brood, 368; Ligurian disappointments, mead, metheglin, and hydromel, 383; dressing hives and feeding swarms, 384; a city of, queen laying eggs in one cell, artificial swarms, 402; Ligurian disappointments, 418; in Egypt, 419, 436; artificial swarms, 420; bar-frame hives, 435; at the Manchester Exhibition, 438; promoting swarming, confining, 455; trapping drones, united swarms, swarms, foul brood, destruction of drones, honey harvest, 456
Begonia Pearcei culture, 81
Berkeley, Rev. M. J., 344
Berks and Hants Poultry Show, 309
Bignonia—argyreo-violascens, 81; radicans, propagating, 266
Billbergia sphaeelata, 410
Bindweed, destroying, 373
Bird dealers, 90
Birmingham Rose Show, 351; Albion Pigeon and Rabbit Show, 418; Poultry Show, this year's, 423
Bletia Sherrattiana, 410
Bog soil, trees for, 110
Boilers—tubular, 13; piping one will heat, 54; improved saddle-back, 89; for heating three houses, 93; management of, 133; heated by kitchen fire, 151; heated by gas, 199; and their bursting, 232
Bones, dissolving, 109
Border, plants for shaded, 109
Botanic (Royal) Society's Shows, 236, 277, 368, 375, 392, 425; florists' flowers at, 443
Bottom heat, 168
Bougainvillæa glabra, 300
Bowiea volubilis, 28
Bowling-green making, 217
Box—cutting, 217; edgings, trimming, 281; cutting, 307
Brahma Pootras, 156, 349, 382, 434; characteristics, 40; at the Bristol Show, 76, 96, 112, 136; and Grey Dorkings, 140; breeding Dark, 170, 186, 200, 267, 302, 317; food they consume, 187; vulture-hocked, 189, 284; usurpation, 199, 219; combs and hocks, 213, 219; not hatching, 220; crosses in dark, 236, 238; coughing, feathers, 240; colour of dark, 253; size and symmetry of, v. Hamburghs, 254; comb of, 269; pea comb, 285; chickens losing feathers, 320
Breasts, crooked, 20
Brent, Mr. B. P., 71
Brighton Poultry Show, 454
Bristol and Clifton Poultry Show, 35 56, 78
Broccoli for spring, 268
Bulbs after flowering, 414
Bullock's liver for fowls, 240

Cabbage—culture, 149; new, 150; manuring, 163; sowing, 192; early, 283; Veitch's Improved Matchless, 431
Caladiums—rootstocks decaying, 134; culture, 150, 152; growing specimen, 184; liquid manure for, 453
Calceolaria cuttings, 185
Californian items, 69
Camassia esculenta culture, 994
Camberwell, beware of, 366
Camellias—stocks for, leaves yellow, 32; buds falling, grafting, 54; soil for, 54, 67, 381; propagating, management, 74; stocks for, 93; culture, 118, 225, 244, 276, 293, 361; list of, 119; grafting, 151; green turf for, 184, 210; Mrs. Dombrain, 211; in conservatory-bed, 216; not flowering, tubs for, 218; for market, pruning roots, 234; select, 252; removing, 268; soil and treatment, 292; unhealthy, 316, 414; leaves rusted, 348
Campylobotrys refulgens culture, 292
Canada—friends in, 162; notes in, 229; jottings from, 293; West, 414
Canaries—pairing, 140, 368; with inflamed skin, 156; among Rhododendrons, 220; for an aviary, 256; asthma in, 272; eating eggs, 288; footless, 352; eggs shell-less, 384; prizes for, 401; feathers diseased, 438
Cannas, planting, 348
Carnations—select, 94; and Pinks, supports for, 431
Carrots for fodder, 93
Casimiroa edulis, 84
Cassia corymbosa culture, 316
Catalogues, 4
Catarrh in fowls, 116
Cat, chicken-eating, 402
Cattleya Dowiana, 3 Warscewiczii 263; citrina, 300, 410
Cauliflower culture, 284
Cedrus deodara pruning, 86
Celery—winter protection for, 27; culture, 281, 345
Cerastium tomentosum, propagating, 398
Cereus hexagonus grafting, &c., 266
Chamærops seed sowing, 74
Cheere, Rev. G., 312
Cheltenham Horticultural Show, 425
Chickens—food for, 286, 309; dead in their shells, 368; blistered, 368; killed by kindness, 402; dying, 439; drooping, 456
Chimonanthus grandiflorus from cuttings, 148, 175
Chiswick, vacancies at, 164
Christmas trees, 12
Chrysanthemums—new and old, 100; (Pompone) St. Michael, The Countess, and Madge Wildfire, 211; culture, 279
Cinerarias — culture, 221; sudden death of, 248; flagging, 252, 300; dying suddenly, 279
Citrus—japonica, 147; genus, soil for, 364
Clavija fulgens, 163
Clematis round trees, 216
Clerodendron Balfourii culture, 217
Climbers for walls of dwellings, 133
Climbing plants for greenhouse, 199
Coal—quantity needed, 234; economy in, 319
Cochin-Chinas—cock's comb, 40; White and Buff mixed, 80; cock's eyes, 116; cock, tail of, 135; paralysed, 140; not laying, 172, 384; bow staggering, yard floor for White, 204; legs warted, 256
Cockerell, Capt., resignation of, 130
Cockroaches, 420
Cockscombs for July, 94
Cocoa-nut fibre refuse for the Gladiolus, 252
Cold—intense, 28, 45, 65; minimum, 51; and its consequences, 65, 105, 129, 147, 161, 163, 177, 195
Coleus Verschaffelti for bedding, 364
Columbarian Society, the City, 287
Combs—frost-bitten, 116; varieties of, 116; of cock bleeding, 304
Competitors, let them be fairly matched, 126
Coniferæ at Basing Park, 294
Conifers, fine, 66
Conservatory—heating and planting, 169; glass for south, 184; plants for, 252
Convolvulus mauritanicus for an edging, 110; culture, 169
Cordyline australis, 268
Coronilla dome flowering, 398
Correa potting, 300
Cotton—seed, 13; improvement of promoted by a knowledge of the plant, 127
Covent Garden Market, 13, 32, 53, 73, 92, 108, 129, 151, 167, 183, 198, 216, 233, 251, 266, 282, 299, 315, 332, 347, 363, 380, 397, 413, 432, 452
Cows dropping after calving, 135
Crump in cock's foot, 438
Crataegus oxyacantha, new double, 410
Cream, production of, 172
Crewe Cœurs, 384; head affected, 40; feathers ragged, 403
Crinoline and its consequences, 321
Crocuses—failure of yellow, 252; bulbs, moving, 283; eleven varieties, 410
Croquet-ground, returfing, 316
Cross-breeding fowls, 116
Cross breed of fowls, 186
Crotons, soil for, 381
Crystal Palace, 47; Bird Show, 137; Show, 363, 374
Cucumbers—not setting, 13; failures, 86, 104, 223; planting out, 150; on trellis, stopping, cocoa-nut refuse for, 184; avoiding failures, 193; for cool culture, 234; in pots, 282; continuous supply of, 290; with Mushrooms, 301; bitterness in, 311; growing on ridges, 313; not swelling their fruit, 347; culture, 349; pot-culture, 375, 391; failed, insects in frame, 398; on ridges, disease, 412; training, 452

OCT 15 1910

Cupressus Lawsoniana from cuttings, 161
Currant—buds of Black swollen, 13; culture, 26, 193; Black, bud insect, 74, 380; pruning and propagating Black, 86; tree culture, 193; insect preying on the Black, 288; fruitless, 397; summer-pruning, 453
Curcuma australasica, 28
Cuthush's spring flower show, 227
Cuttings, hotbed for, 94
Cyclamens—frosted, 134; culture, 225, 260; persicum culture, 324; not flowering, 348
Cygnets, feeding, 402

Dahlias for exhibition, 169
Daisies, eradicating, 168
Daisy, Anemone-leaved for edging, 432
Dalechampia Roezliana, 360
Dandelion for fowls, 88
Daphne odora buds falling, 73; indica potting, 300; cneorum, propagating, 398
Daturas, planting, 348
Delphiniums—select, 111; formosum, 364
Deubies, 143
Dendrobium macrophyllum Veitchianum, 416
Deodorising, 397; night soil, 199
Depredators, deterring, 345
Dew-point, 312
Dianthuses, removing, 453
Diarrhœa in chickens, 420, 456
Dick, Mr. Robert, 130
Dictyopsis Thunbergii, 263
Diplademia starting, 54
Disa grandiflora, 195; culture, 348
Dobson, Mr. J., 344
Dombeya Mastersii, 263
Dorkings, 80; Grey and Brahma Pootras, 140; hens spurred, 188; hens picking feathers, 204; points in White, 240; hen's combs, 384, 399; 399; cock paralysed, 402; chickens crooked-breasted, 455
Draining a clayey soil, 413
Drip from room of stove, 151
Drunkeuness, 390
Dubbing-scissors, 116, 402
Ducklings and artificial mother, 384; dying in the shell, 420
Ducks — Rouen, for exhibition, 40; lame, 156; number for a drake, 172; snails for, 352; eggs soft, 256; rearing Call, 304
Dumfries Ornithological Show, 38
Dyckia rariflora hardy, 165

Engings for walks, 61, 100, 143, 222
Edinburgh Working Men's Flower Show, 441
Egg-producing fowls, 116
Eggs—production of, 20; at Birmingham Show, 20; sprinkling while hatching, 40; detecting fertile, number a hen lays, packing for travelling, 80; ill-flavoured, 156; from pullet, 156; removing as soon as laid, 188; imported, fowls for producing, 204; good producers of, 240; packing, 256; chilled, 304; preserving, 304; in fine sawdust, 320; purchased, unproductive, 350; weight of, 352; poultry yard for wholesale production of, 382; guaranteeing high-priced, 415; not hatching, 420; vitality retained in chilled, 435; unproductiveness of high-priced, 454
Elæocarpus reticulatus culture, 218
Embothrium coccineum culture, 452
Entomological Society's Meetings, 8, 87, 163, 180, 262, 326, 393

Epimediums, 283
Epworth Poultry Show, 334
Eranthemum rubroveninm culture, 284
Eriostemon Smithii culture, 218
Essences, fruit, 283
Eucharis amazonica culture, 364
Evergreens—for a blind, 32; not generally known, 158; pruning, 217
Everlasting flowers, 13
Example, a worthy, 311
Exhibited fowls injured, 34
Exhibitions, horticultural, in June, 395

Farfugium grande, hardiness of, 142
Feather-eating fowls, 420, 438
February, hardy flowers in, 177
Fernery—constructing, 94; charcoal fire in, 217; slugs and woodlice in, temperature, 284
Ferns—for a fernery, 184; losing their fronds, 218; temperature for, 252; culture of Filmy, 305; Golden not thriving, 316; acclimatisation of New Zealand tree, 391; blackened, and woodlice on, 398
Ferrets, 384
Figs—the Channel Islands, 44; trees, cutting back, 168; out of doors, 379
Fir and Pine, 73
Fittonia argyroneura, 360
Fleas in poultry-house, 204
Florists' flowers at the Royal Horticultural Society's Show, 222
Flower gardening, jottings about, 442
Flowers—and their associations, 175; beds, size and separation of geometrical, 210; planting, 252, 253; destroyed, 267; and their fitness, 294; pots, cleaning, 348; preserving colour of dried, 398
Flues, lime cement for, 253
Foliaged plants, ornamental, 421
Forcing-house temperatures, 110
Forcing flowers, art of, 246
Foreman's management of fires, 144
Fowls—exhibiting borrowed, 34; mutilating a competitor's, 55; for a cottager, 55; throats disordered, 80; lungs, abscess in, 93; dung as a manure, 111; food required for, 116; breathing with difficulty, 116; catarrh in, 204; dung for liquid manure, 217; disordered, useful, 220; trespassing, 234; cottagers', in Sussex, salt for, 254; eating feathers, 272; desirable kind, 272; failures with, 304
Frame, uses of, 74
Frames, &c., 215
French varieties of fowls, 220
French Lavender, 253
Frosts—excluding, 52; of May, 376, 378, 423; of January and May, 386
"Fruit Garden, The Miniature," 104
Fruit, essences of, 283; artificially flavoured, 429
Fruit-trees, shoots, pinching, 84; transplanting large, 117, 162; pinching shoots of dwarf, 251; house for growing, 317; prospects, 372, 376
Fuchsias — potting, 167; for exhibition, 169; list of hardy, 453
Fuel, economising, 167
Fumigating, plants injured by, 74
Fungi, parasitical, 71
Furnaces, management of, 133
Furze, cutting down, 284

Game fowls, 20, 418; cocks fighting, 20; points in, 83; breeding Duckwing and dark blood Pile, size of cocks, 60; breeding, 75, 153, 170, 185, 201, 237, 285; with different legs, food for, 80; characteristics, 95, 131; colour of yellow Birchen hen, 172; what trees and shrubs are not injured by, 148, 175, 210; not laying, 240; origin of, 334; hen's comb, 368; cock's beak damaged, 384; cockerels, 256; crossing for colour, 268; varieties of colour, 302; breeding this year, 458
Gapes, 304; in chickens, 415, 420; administering camphor for, 438

From observations taken near London during the last forty years, the average day temperature of the week is 42.2°; and its night temperature 29.9°. The greatest heat was 57°, on the 3rd, 1860; and the lowest cold 4°, on the 2nd, 1854. The greatest fall of rain was 0.86 inch. N.B.—The Calendar contains the names of plants flowering in the greenhouse.

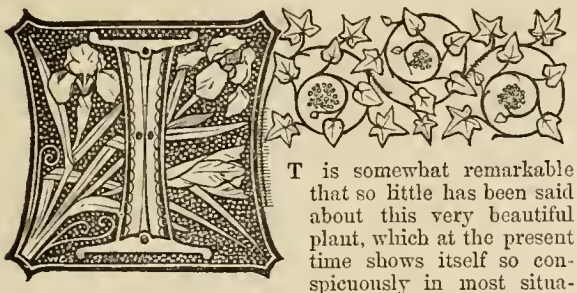
THE PAMPAS GRASS.



IT is somewhat remarkable that so little has been said about this very beautiful plant, which at the present time shows itself so conspicuously in most situations in the south of England. Is it thought not to be hardy enough to withstand severe winters, or has the novelty which it possessed when it was first introduced died away? Its beauty cannot be said to have done so, for nothing can be really more attractive than some of the specimens on which upwards of a hundred plumy spikes testify to the profuseness of its blooming, while its gracefulness as a plant entitles it to a place where its blooming is even more uncertain than in some favoured localities. Certain it is that the Pampas Grass is less grown than it ought to be. Many places of considerable size contain only a single specimen. As it is not over-nice in regard to situation it is deserving of being planted more largely than it has been. Except in one or two cases it has not as yet perfected seeds in this country, and therefore, as it does not naturally increase itself here by selfsown seeds, suckers, or layers, it must be propagated by other means. Fortunately these means are not difficult, and if there were a demand, young plants could be had in any quantity. I will now offer a few notes on the culture of this most beautiful of all autumn-flowering plants.

However objectionable some situations may be to the plant, certainly the character of the soil makes little difference to it. I have seen it thriving well on a dry rocky hill, and equally at home by the side of a pond or ditch; and the description of soil seems, indeed, to have less effect than the presence or absence of moisture, for I have seen it flowering in the greatest perfection on the black peaty soils of Bagshot, and here a plant is doing pretty well on the stiffest of clays. I think that it always requires sunshine to do well, and very probably it will succeed best where there is sufficient moisture without stagnation, for the best plant which I ever saw was growing by the side of a piece of ornamental water in the garden of J. Hollingworth, Esq., near Maidstone. This plant about three years ago had upwards of 120 spikes of bloom upon it, and I believe that number has since been much exceeded. The soil rested on Kentish rag, or what in other places would be called limestone, Other plants at the same place, growing in various positions, were also flowering well; but I believe that the whole had the advantage of sunshine at all times.

Free-blooming as the Pampas Grass is, there are times when its non-flowering is difficult to account for. Many years ago I planted one out in a dell amongst shrubs, the situation was moist rather than dry, and the plant grew and flowered for a few years, and I believe was amongst the first that did flower out of doors; each succeeding year added to the number of its spikes until in the bright warm summer of 1859 there was a blank—no flower, although the plant grew as fast as before, and seemed all right. Unwilling to remove a plant that was favourably situated, it remained throughout the next year, during which comparatively few plants of this species flowered, a circumstance which seemed attributable to the dull wet character of the summer. The severe winter which followed killed many plants of Pampas Grass in different parts of the country, and did not leave this one entirely unscathed; its non-flowering in 1861 was therefore excused. The plant recovering its former vigour, half a dozen blooms were produced in 1862, which, being less than it had furnished in 1858, was anything but cheering; and in 1863 and 1864 it was altogether destitute of flowers. This, of course, led to the plant being condemned, and having been taken up in the spring of 1865 it was divided into a number of small plants, some of which promise to do well, one or two being in flower at the present time. Now, how is the plant's not flowering in seasons, when other specimens did so to be accounted for? The situation, I have no doubt, exerted a considerable influence, for some trees and shrubs grew up and partially shaded the plant, and though it continued to grow no flower-stems were produced. In some situations a greater number of flower-spikes will be found on a plant of a given size than on another differently placed. We have here one or two specimens which seem as large as that referred to as having had upwards of 120 spikes of bloom upon it, yet we have never at this place reached half that number. The plants here are mostly growing on a dry stony soil. I believe the Pampas Grass suffers much from the roots of trees encroaching on it, and possibly this assisted the other cause in preventing the specimen in question flowering. It is certain that the Pampas Grass prefers being alone to contending with other plants for the occupation of an allotted space of ground; and it is equally true that it looks best when in such a position, for few plants can equal and still fewer excel it for symmetry of growth and a uniformly good appearance on all sides; it therefore deserves an open position, so as to exhibit its beauties to the greatest advantage.

Independently of its dislike to shade, or rather contention with other plants for support from the ground which it occupies, I believe that the Pampas Grass flowers more or less freely according to the varieties that are grown; for there are certainly different shades of colour, and possibly some varieties may be earlier than others. A somewhat dark-coloured one is often regarded as the earliest, though it is by no means the prettiest: the narrow-leaved plants also often furnish bloom earlier than the broad-leaved—that is, small plants begin to flower sooner; this is a consideration, for at best the Pampas Grass is not the quickest of plants to come into blooming, and some have to wait three or four years ere they have any bloom worth mentioning. Neither is it the best in the world to

propagate, for it sometimes happens that a stocky-looking plant that appears to invite being pulled into twenty pieces, with a little root attached to each, will be found not to yield more than three or four plants a few months afterwards. This, of course, is where they are left to take care of themselves; nursing in a proper propagating-house or ground will in many cases insure as many plants as offsets. The Pampas Grass is also not one of the easiest of plants to transplant; losses arise with it quite as often as with evergreen shrubs, yet the latter drawbacks are trifling, and ought not to prevent a more extensive cultivation of this charming autumn flower, which deserves a place wherever there is a chance of its flowering; and even in places where this is uncertain an isolated plant or two on sites judiciously chosen give a sort of tropical aspect to the spot not afforded by anything else. It would, however, be well if the farthest position northward at which the plant flowers were made known through the pages of this Journal, so that intending planters might know how to base their expectations. I believe the plant is much affected by the impurities of large cities, and is therefore not adapted for the London squares, but of this I am not sufficiently informed.

It has often been a matter of regret that this plant does not flower earlier, and a summer substitute for it has been suggested in the shape of Arundo conspicua, a pretty graceful-growing plant, but the paucity of the flowering spikes and their smallness, although borne on stalks as long as that of the Pampas Grass, renders it only a poor substitute; other kinds, however, may prove more suitable, and even earlier-flowering varieties of the Pampas Grass may in time be obtained. As it is, there seem to exist variations in the times of flowering as well as in the colour and formation of the spike. This is more interesting than if there were no variety, and affords another reason for a more extensive cultivation of the plant. —J. Robson.

NOTES OF AND ABOUT ROSES.

1. Importation from France.—I have read with satisfaction the protest, at page 404, against the wholesale importation of new Roses which are annually sent from France to tempt the unwary, and deceive even the most practised rosarians. Long before the publication of the article above alluded to, I have had it in mind to again direct attention to this subject, with the view of ascertaining whether it is possible to find some expedient for mitigating the plague yearly inflicted on the Rose-growing and Rose-loving public. At present there are but few signs of any abatement of the evil, for evil it assuredly is in many respects. It is a severe tax upon our patience; not much less so upon our purse, upon our credulity, upon our time; for it is a waste of time in propagating a large number of kinds "to prove" them to be worthless, and therefore a waste of material on account of a useless application of it. I am aware that these expressions will not be deemed "orthodox" by some of our more enthusiastic Rose friends, but it is necessary to speak out, and that, too, without reserve.

If a really good Rose makes its appearance, it matters not whence it comes, we welcome it, and accept it with due honour and delight; but so often do we have to glean it out amidst a host of worthless or indifferent companions, that the task becomes dispiriting, and we begin to regard with suspicion every new-comer. It is not simply good Roses that we should seek for out of the new announcements, but better ones—that is, such as show some marked improvement or new feature in advance of kinds we already possess, particularly as regards form, colour, and size, combined with healthy habit and constitution.

I believe that the majority of our nurserymen with whom the cultivation of Roses is one of the most important subjects of their business, regard, not simply with dislike, but with aversion, the thankless task of propagating so many new kinds annually, when experience has shown that only a few, a very few, will remain sufficiently long in favour to be both profitable and useful. Various remarks inserted in their catalogues seem to intimate this feeling rather strongly, still more so the number of names yearly expunged from their lists, previously inserted because they were new. That "Index Expurgatorius" of Roses, issued from Sawbridgeworth, though somewhat too rigorous to please most of us, is a notable advance in the right direction, and a severe but telling evidence on the part of the veteran horticulturist whose name it bears. The impatience of the numerous Rose amateurs to possess and try novelties is, doubtless, the great cause of the demand being supplied, and while the demand continues the supply will be sure to follow. I do not propose, however, to discuss this matter further than stating my belief that if purchasers would only wait a sufficient time, for the truth would be sure to come out, propagators would be relieved from a great burden, and the time, labour, and expense of increasing inferior Roses would be more economically applied, and more profitably too, by a more cautious and restricted selection from the host of new seedlings every year produced in France. I anticipate, therefore, no detriment to the interests of the growers who import them, but, on the contrary, much prevailing dissatisfaction would be removed; greater confidence and increased demand for what is really good would be substituted.

More convincing than any argument will be the statement of a few simple facts relating to the actual number of Roses raised in France during several consecutive years; a comparison of the total number with the actual number of the same period at present in the best trade catalogues will show very pointedly the extent to which this annual importation is attempted or actually carried on. By the Roses of any particular year is meant those sent out by our own nurserymen in the spring of that year, and, therefore, first known to us in the course of the season following, although announced by the French growers in the autumn previous. As we know at present but little of the past year's Roses, and almost nothing, except by name, of the batch recently published in these pages, no mention is made of any of them in the lists about to follow, nor are they included in any of the numbers about to be given. I therefore select the five years preceding last year—that is, from 1861 to 1865 inclusive.

The number of new Roses sent out during that period stands as follows:—

	1861	1862	1863	1864	1865
Hybrid Perpetuals	51	53	67	48	69
Bourbon	3	3	4	6	7
Teas	3	5	4	3	2
Other kinds	3	4	5	1	5
Total	40	65	80	58	83

In all 326.

If this number is not strictly accurate, the defect arises from the circumstance of M. Eugène Verdier publishing his announcements sometimes on a separate sheet. In one instance (1862), I have lost or mislaid this sheet; the total, therefore, is deficient by the number of Roses sent out by M. Eugène Verdier in that year—probably six or eight.

The number of new French Roses annually announced in the catalogues of our principal growers varies, of course, according to the number sent out in France. In the five years 1861-5 the numbers varied from about thirty-five to forty-eight; the actual number introduced during the whole period, therefore, scarcely exceeded two hundred, leaving about one hundred and thirty that have probably never been introduced into this country. In some of the best catalogues not more than one hundred of these two hundred are now inserted, in several less than one hundred, and in one above alluded to I do not think there are fifty. In Mr. Radclyffe's list of the best Roses at page 202, there are but twenty-five that belong to this period.

During the same five years there were about a dozen English seedlings and Roses sent out by our own growers, five of these are in Mr. Radclyffe's list, and some of the others are still regarded with favour.

These facts speak for themselves.

2. Who Raised Our Best Roses.—I quite agree with "D., *Deal*," that before attempting to estimate the merits of a new and unknown Rose from the character and description given of it by the raiser, it is some help to our estimation to know the name of the raiser (especially in the case of French Roses), that we may judge from his antecedents what amount of confidence may be placed in his announcements. Our own nurserymen, as a rule, do not affix the names of the raisers of French Roses published in their catalogues, unless for some distinctive purpose, as in the case where the same name has been given to two different varieties, which has more than once occurred; thus we have had Souvenir de Comte Cavour (Margottin), and another of the same name by Robert et Moreau, also Maréchal Souchet (Damaizin), and another by Guillot fils, and the name of the raiser is added no longer than while both kinds are retained in the catalogue. In the first instance, Robert et Moreau's Souvenir de Comte Cavour was dismissed the second or third season after its appearance, while Mar-

gottin's ranks among the best Roses in cultivation, although Margottin's name is no longer affixed to it. In the second instance, some growers retain Damaizin's Maréchal Souchet and reject the other, while some prefer that of Guillot fils. It is true that not much confusion is likely to arise in this case, as neither of them will now become popular, not even occupying a second rank.

The names of the raisers of our best Roses are scarcely known among cultivators in connection with particular flowers, and not always remembered by the most distinguished rosarians. It will, therefore, not be uninteresting to recapitulate some of the best Roses that appeared during the five years I have selected, in connection with the names of the raisers. It will serve to remind the reader to whom we are indebted for them, and to judge from these data what amount of credence may be placed in the announcements recently published, and ably commented on by "D., *Deal*," but which it must take at least two seasons to prove.

I take for my basis the list given by Mr. Radclyffe, or, more correctly, those of that list that were introduced during the period; there are twenty-five, exclusive of English Roses. To these I add others, not of equal merit, but so good and generally approved that they will continue in favour till surpassed by others of a similar character. I may be pardoned for alluding here to a former article, my statements in it having been misunderstood by the correspondents who followed on the same subject. In giving a list of the best Roses of 1865 it seems to have been inferred that I had put them down as being *the* best Roses, whereas it was only intended to point out which were the best of that particular year.

There is a difference of opinion regarding four in Mr. Radclyffe's list—viz., Duc de Cazes, General Washington, Sœur des Anges, and Professeur Koch. The first, though unsurpassed in its colour and size, opens badly, and too frequently yields a large proportion of imperfect flowers to only one good one. If it were constant, and as fine as Mr. Radclyffe grew it at Rushton, its place in the first rank would be indisputable. The fault of not expanding is still more applicable to General Washington, which rarely produces a perfect flower. Sœur des Anges is partly objectionable from the same cause, as well as inconstancy in colour, which probably arises from its being a sport. Professeur Koch is worthless here, but as Mr. Radclyffe is confirmed by Mr. W. Paul and Mr. Rivers, the authority for giving it a first place is too strong to controvert.

With the above qualification I submit a list of the best Roses sent from France during the five years 1861-5, with the names of the raisers.

EUGÈNE VERDIER.

Madame Charles Wood	Dr. Andry
Professeur Koch	Rushton Radclyffe
George Prince	Madame Versehaffelt
Madame Victor Verdier	Leopold Premier
Prince Camille de Rohan	Alpaïde de Rotalier
Madame Caillat	Maréchal Niel
Joseph Fiala	

The foregoing list shows that we are indebted to M. Eugène Verdier for several of our best Roses, notwithstanding the severe censure that has been occasionally passed upon him on account of the great number he sends out annually. That he does this to a fault cannot be denied, and it would be well if he withheld the inferior kinds. I am not quite certain if I am correct in assigning Leopold I. and Alpaïde de Rotalier to him, having mislaid or lost his list for the years in which these Roses were sent out. Maréchal Niel was raised by an amateur named Pradel, but *mis en commerce* by M. Eugène Verdier.

CHARLES VERDIER.

Duchesse de Caylus	Vicomte Vigier
Madame W. Paul	François Lacharme

The first two are very properly in Mr. Radclyffe's list. The last is a superb Rose, but of weak growth.

LACHARME.

Charles Lefebvre	Xavier Olibo
Alfred de Rougemont	Madame Charles Verdier
Baron A. de Rothschild	

To Lacharme belongs the honour of raising the best crimson Rose known. The last two, I am inclined to think, require further trial.

MARGOTTIN.

Souvenir de Comte Cavour	Jean Goujon
Mdlle. Amélie Halphen	Rev. H. Dombrain
Charles Margottin	Louise Margottin

Nos. 3 and 4 have been proved here to be well worthy of a place in the Rose garden, though somewhat too rough for exhibition purposes. 5 and 6 are Bourbons not yet surpassed in their class for colour and form.

GRANGER.

General Washington	Duc de Wellington
Mauriee Bernardin	Leopold Hausburg
Baronne Pelletan de Kinkelin	

2, 4, and 5 are the best.

GUILLOT FILS.

Eugène Verdier	Abbé Berleze

No. 1 is distinct and good.

GONOD.

Madame Moreau	Achille Gonod	Celine Gonod

No. 3 is a very pretty Bourbon of satiny rose colour, with slightly incurved petals.

OGER.

Sœur des Anges	Belle Normande

LECOMPTE.

Maréchal Vaillant

One of the best and certainly one of the most Perpetual Roses known. I have had blooms of it in all weathers, from the end of May to the middle of December, in the past season.

TOUVAIS.

Duc de Cazes	François Louvat
Semiramis	Julie Daran

The last two must give place to many better in the scarlet crimson class.

DAMAIZIN.

Alphonse Damaizin

Of perfect form and colour, but hardly strong enough in constitution.

PORTEMER ET FILS.

Pierre Notting	Charles Wood	Jean Rosenkrantz

LIABAUD.

Clemence Joigneaux	Mons. Boncenno	Madame de Canrobert

The third was one of the best, if not *the* best Rose shown at the National Show at Kensington last summer; it was in Mr. Cant's box. Like too many other fine Roses, as Furtado, Vidot, and Mdlle. Bonnaire, it is reported to be not sufficiently vigorous to be a first-class kind.

LEVEQUE ET FILS.

Duc de Rohan	Elise Vilmorin	Madame Derreux Donvillé

All of these are surpassed by others of similar colour. No. 1 is in Mr. Radclyffe's list. No. 3 is very good.

JAMAIN.

Madame Boutin	Marguerite de St. Amand

Both first-rate. No. 2 is probably the best light Hybrid Perpetual in cultivation.

By stretching my leniency to its utmost, I can find but fifty-seven out of three hundred and thirty sent out during the five years 1861-5 that I consider at present to be worth cultivation. To the rosarian it will be evident that many of these must be dismissed before long.—ADOLPHUS H. KENT.

(To be continued.)

THE GREAT SHOWS OF 1867.

WHILE taking note of the dates fixed by the various societies for holding their great fêtes for 1867, I have been sorry to observe that the National Exhibition at Manchester and the five-days Show of the Royal Horticultural Society of London are appointed so that it is impossible for the same exhibitors to attend both Shows. I think this is much to be regretted, as no doubt the object of both Societies is to collect into one focus as much of the horticultural and floricultural skill of the country as possible, and, of course, by so doing, they deserve the liberal support of the public. In those respects the one is sure to interfere with the other. Of course the Royal Horticultural Society has a right to be looked upon as the premier Society, but as the Manchester folks had advertised the date of their week's Show long before the Royal Horticultural Society gave notice of theirs, would it not be a graceful act to pay some deference to that which had every prospect of affording the toiling thousands of the great emporium of trade such a feast of beauty as they never saw before? As one who has not the slightest personal interest in either fête, I think it a very great pity that some arrangement could not be made by which the two great Shows should be made available to all exhi-

bitors, and doubtless there are such, who wish to attend both gatherings.

It is a pleasing thing to see these Societies profiting by the example set by the International Horticultural Exhibition of 1866, and determining to keep their fêtes open for nearly a week; thus, by varying the price of admission on various days, affording an opportunity to the millions to pay pleasant court to Flora and Pomona. It is now a recognised fact that if shows are to pay and societies to exist, the basis of their constitution must be widened in the matter of admission, so that the general public can have an opportunity of seeing the gorgeous flowers and fruits brought together on such occasions; and I think that this, the first great attempt of "Cottonopolis," with its toiling thousands, should have as little opposition as possible.—D. Thomson.

P.S.—In the advertisement of the five-days Show of the Royal Horticultural Society, which appeared in the last Number, you have printed July for June.

[The dates given were those sent to us. A corrected advertisement appears this week.]

ROYAL HORTICULTURAL SOCIETY.

Weekly Show, *December 22nd.*—Mr. Wm. Bartlett, Shaftesbury Road, Hammersmith, was awarded a first prize for a collection of Primulas, &c. Mr. B. Brown, gardener to R. H. Wyatt, Esq., Wandsworth Lodge, Upper Tooting, had also a first prize for a collection of flowering plants. A collection of plants consisting of Camellias, Hyacinths, Primulas, Tulips, and Heaths, was exhibited from the Society's Garden, Chiswick. Mr. B. Brown, gardener to R. H. Wyatt, Esq., obtained a first prize for a collection of fruit; and Mr. T. Neale, gardener to R. A. Cartwright, Esq., Edgcott House, Banbury, was awarded an extra prize for a Smooth-leaved Cayenne Pine Apple.

December 29th.—On this occasion an extra prize was awarded to Mr. W. Bartlett, Shaftesbury Road, Hammersmith, for a collection of flowering plants; and a collection of Cinerarias, Heaths, Mignonette, &c., from the Society's garden, Chiswick, completed the exhibition.

MARKET STRAWBERRIES.

One word more, and I have done with this subject. I do not recede from my original list. The varieties I named are all sure and great croppers. It is pleasing to me to find that "Ecila" adopts these sorts named by me in my two last communications: Empress Eugénie, Frogmore Late Pine, Marguerite, Sir J. Paxton, and Wonderful. Patrick's Seedling is a good cropper, and a good Strawberry. With regard to the others, British Queen is not to be depended on. Amateurs, even, are hereabouts giving it up. Cornucopia was raised by the late Mr. Nicholson. I do not know it. Comte de Zans, Alice Nicholson, and another Strawberry, were kindly sent to me by Mrs. Nicholson this spring in an envelope; but they were so much dried, that, though carefully potted, they died. La Constante is a wonderfully good Strawberry, handsome, level, beautifully formed, of distinct and delicious flavour, suited to strong land and a northern aspect. It is a great cropper, and would be an admirable market sort were it not apt to burn in hot seasons in some lands, and slow to reproduce its plants. It is of the same tufted formation as Rivers's Eliza. Mr. W. Prince, of Flushing, says, "it burns considerably, and is a poor cropper!" I agree to the former, not to the latter. Myatt's Eleanor is a noble wedge-coned Strawberry, but a fitful cropper. It is entirely superseded (also Elton Pine, a very good market sort), by the four late Strawberries, Wonderful, Cockscomb, Dr. Hogg, and Frogmore Late Pine. They are hardy, sure setters, great croppers, mostly large fruit, and more or less Queen-flavoured.

As Wonderful and Frogmore Late Pine seem to be agreed upon, let me induce market gardeners to try Dr. Hogg and Cockscomb. These four will distance British Queen and Carolina Superba. If flavour is not a matter of great consequence, Cremone's Perpetual, Hooper's Seedling, and Ananas Lecoq would do.

I agree with "Ecila" that it is desirable that market gardeners and gentlemen's gardeners should relate their experience. I shall in due time be found to be right. I am no puffer, and will be no party to appraising commodities, no matter by whom they are raised or sent to me, to the deception of the British public. I have always been guided by the nature, and not by the names of persons or things. I have "The Lady," strong plants, on trial. It will gratify me much if I be able to speak favourably of her. Mr. Turner says Dr. Hogg is first-rate.—W. F. Radclyffe, *Okeford Fitzpaine.*

PLANTING PEAR TREES.

My principal motive for writing is to state my objections to the practice which Mr. Abbey recommends. "Holes 9 feet square (see second column, page 460), should be dug, and of such a depth that the stem will not only be as deep in the soil as it was before, but so that the union of the stock and scion will be covered to the depth of 3 inches."

No hole in any cultivated garden need be more than from 3 to 4 feet in diameter and 20 inches deep, and the covering of the junction of the bud or graft with the stock, as fully pointed out in your columns last spring, pages 180, 193, leads to injurious consequences, for besides placing the tree by far too deeply in the soil, it induces the putting forth of roots from the graft, by which the effect of the Quince stock in giving fertility is destroyed. Here, where there are more Pear trees old and young on Quince stocks than in any other garden in Europe, great care is taken every spring when the ground has been slightly dug to bury the weeds, which in seasons like this we are reluctantly compelled to do, for digging among bearing trees should be avoided. Great care is taken to withdraw all loose earth from the base of the tree, so as to leave a space of about an inch between the swollen junction of the graft with the stock and the surface of the ground. This mode of culture has been followed here with Pear trees on Quince stocks twenty to twenty-five years old, and is the only sound method of culture.

In planting, I may add a word of advice. Before the tree is placed in the hole throw in some loose earth in the form of a mound in the centre of it, tread it gently, and on this place the tree; no sinking will then take place, so as in wet soils to have the roots in a basin of water.—T. R.

CATALOGUES.

With regard to the subject entered upon by your correspondent, "Monticola," I may observe, that terrible as is the cattle plague, the catalogue plague is in some respects worse. Though the symptoms are different in the two, they are equally contagious and destructive, the former of bulls and cows, the latter of truth and confidence. Queen, Lords, Commons, the farmer, the justice, and the peasant, have with one will agreed to stamp out the cattle plague; but the catalogue murrain still rides rampant.

The progress of this terrible complaint was arrested for a time a while ago, by a few indignant spirits, and the name your humble servant gave to the "fat" catalogues will cling to them for ever. An abatement of symptoms, temporary, alas! and illusive, ensued, only to be succeeded by an outburst more violent and destructive than ever. Fatty degeneracy of the worst form has set in; who shall arrest the downward course? Let the young, bold, muscular horticulturists of the day, and there are plenty, who are the consumers of these wares, set their faces at, turn up their noses at, shake their heads at, drive their quills at, and withdraw their support from, the great imposture.

Let me recommend to a certain large class of your readers, a good commercial speculation—to wit, a catalogue which shall "tell truth and shame the ——." It would pay, sir—it would pay.—***.

EARLY PEAS.

Seeing a remark about Peas in The Journal of Horticulture, I am induced to say a word in favour of Dickson's First and Best. I have grown for the last ten years several of the new Peas as they came out. As regards Dickson's First and Best, I can most unhesitatingly affirm that it is the very best early Pea I ever grew as regards earliness, productiveness, and quality. It may be that there is a difference betwixt "Theta's" soil and mine, as it is a well-known fact that what will do well in one place will not answer satisfactorily in another; but if the Pea in question does not suit "Theta's" soil, that is no

reason why it should not suit that of other localities, and I would recommend gardeners to grow it, and prove it for themselves.—J. Eastwood, *Gardener to E. Nathan, Esq., Didsbury.*

OUR VINES.

"Our Vines," as we always call them, though they belong to Cousin Herbert. He lives near to us, just over the wall—an ugly red brick wall, built by a neighbour who did not like us. Well, these Vines had been thought and talked about for years. Great piles of sods had been laid together in heaps until they crumbled into soft mould from very old age. Every known preparation had been made for them, everything done for them that could be heard of or read about in books, from McIntosh and Thompson down to the last weekly and monthly magazine. Great thought, and talk, and curiosity, gathered about this was-to-be new vinery, some saying one thing, some another, all the household seeming to have a right to argue and dispute, as if Cousin Herbert had not long since come of age. Uncle Tetley said, "It was a very foolish idea, would not pay cost for the land covered, only cause their highly-rated house to be rated higher still;" and Aunt Margaret said, she "was sure they were not rich enough to have such a place, and that every mouthful would cost a shilling, if, indeed, we ever managed to grow any." But yet the work went on, foundations were dug, beeks pored over, fresh soil laid up in heaps for fear there should not be enough, scrapings from the roadside, sods from a field and a neighbouring common—wherever a bit of grass grew that could be spared it was deemed to the great heap under the wall. How often this heap was contemplated I cannot tell, but it appeared ever to give satisfaction to the inspecter. Now it did crumble into pieces just like the dust soil found under old evergreens. It had rested idly under that west wall for five years, and when turned about had a rich moist look, for every bit of grass and fibre had rotted away. Then came cartloads of manure. This, too, was put down under the west wall; a west wind filled the house with its odour. Cook said she had "no need to season her dishes, it was done for her." Next came bags and bags of bone dust. Our wondering neighbours asked if we were going to open our stately mansion for a flour depôt. Then came loads of leaf mould black as coal. "Grand stuff this," said the man who brought it, "fifteen year old if it's a day, worth its weight." Next came lime rubbish. Cousin Herbert had had some trouble to obtain it. It was the plaster, and dust, and bits of lime from old bricks, and the pulling down of a bank just furnished the opportunity of obtaining it. This lime rubbish was put down alongside of the leaf mould, and a gentle breeze blowing put a thin coating of it over everything, as if the first snowstorm had come. Then all the woollen rags we could find were put together, old coats, waistcoats, and such like torn into shreds, or cut into small pieces and laid by the side of some crushed bones, the last arrival. So all the heaps were side by side under the wall, fibry loam, leaf mould, manure, crushed bones, lime rubbish, woollen rags, and bone dust—mounds of such strange size and appearance, I think poor Boffin would have been distracted.

During this time the fair structure was reared, space and capabilities for eleven Vines. Then the Vine-bed or border was made, dear me! with what minute care. A little soil mixed with the crushed bones forming the lowest deposit. "This is the solid food not yet proper for the infant Vines," said Cousin Herbert, as we stood watching. "They will have arrived at an adult age before they reach the ale and beef cellar, for you see they have to grow down as well as up." Then all the mounds were carried away bit by bit; even the woollen rags disappeared; layer after layer, first of one sort, then of another, till the border inside and out would hold no more.

What work there was about this border, to be sure; no one must dig in it, or tread upon it, or plant plants in it, or sow seeds in it. Cousin Herbert was so very particular he watched it night and day. I often wonder he allowed the weeds to grow. Then we had so much trouble, for Aunt Margaret would walk across it coming to our house, because she said it was nearer, though it only saved 3 yards; and Cousin Janet would in spite of all we could do or say, sow her Mustard seed in it. Poor thing! she never knew how often we pulled the seed up before it grew. I think the deposits must have been put in too lightly, or some father mole had chosen the site for the manipulation of a new home, for little hollows or sinkings we could not account for were constantly appearing. Uncle would have it somebody's hens came there to scratch; and yet they could not, for the holes were no larger than sparrows make in any bit of gardening done up with great care, and the more care taken with it the more they go there to bathe or roll themselves.

After this there came the eagerly discussed question, Where were the Vines to be purchased? "Oh," said papa, "I would not go to any of these men with their long puffing advertisements, it is all show and no good."

"No," said Uncle Tetley, "I would go to some quiet unheard-of experienced gardener."

"Yes, and then if they all turn out rotten you will get no recompense," said Cousin Herbert, looking down tenderly upon his new Vine-border; and well he might, for it was nearly all his own hard work.

"I would not go to a young man anyhow," said papa, "for he will think he knows everything, and yet if you go to an old one they will say he knows nothing."

"I am not sure all the Vines in the world are worth this," said Cousin Walter, rubbing the blisters inside his soft white hands. He had spent his Saturday's half-holiday helping his brother, and was not used to a spade and barrow. "I would go somewhere for them, where I could purchase them old enough to bear next year. There is no good in waiting until you are too old to enjoy them."

At last the decision was made, a nurseryman of high standing was chosen, the choice of the Vines left to his better and more practical judgment. A man was sent over with them to plant them, the vinery and border having been previously examined and declared almost perfect in their arrangements and ingredients. There were one Lady Downe's for the centre, six Black Hamburghs, two Muscat Hamburghs, and two Reeves' Muscadine.

It was an October afternoon, a clear white sky with crimson bars, a cold wind going up and down making hard lines and crosses in every pond and gutter, and crisping up the noisy autumn leaves. The sun shone into the new vinery for a few minutes, lighting up the empty space and touching the pale, thin, unpromising-looking canes, the return for so many pounds.

"You will not need to put a fire in here yet for the sake of the Vines," said the gardener who planted them, "but you must keep out the frost, or it will spoil your plants."

I will tell you about these plants some day if all is well.

"A fire, indeed!" said Aunt Margaret, "it will take a barrowload to fill that big grate; we cannot afford it, and coals rising every week. I think Herbert has gone clean out of his mind."

So at last we had our vinery, at which people laughed, and predicted doleful things. An amateur's Vines succeed, indeed! They needed a professional gardener to make them do that, and even then they did not always, and at Uncle Tetley's they kept no regular gardener, only a man once a-week or so to tidy up. "To think that a gentleman with a fine education should come down to wearing an old coat out at the elbows, and to dig, and mix up, and barrow, and tear, and work like a common man, all for the sake of growing Grapes better than his next door neighbour, was ridiculous." So said the gardeners about ——.

"I wish the Vines were at Jericho," said Cousin Janet snappishly, or growing still in that Bradford nursery, for you can talk about nothing else."

"I wish he had never built it," said Cousin Kate, "for I am afraid it will lead to nothing but trouble, and work, and cost, and dirt. Only this morning Herbert said, 'Now you girls must look after that place to see all goes right.' No, it will lead to nothing but bother, and dissension, and failure, utter failure; and instead of growing such Grapes as were never grown before, we shall be laughed at by the whole country side." Nor was this all; the servants complained, called the vinery "a nuisance." The one-day-a-week man refused to clean up about the boiler; as a great favour he would make the fire; but then the very best fires will not keep in for a week, and what was to be done then? An old man in the village was hired to do what others would not; but he was very expensive, and very troublesome; and cook said, "It was wearisome, for he was always going past her kitchen window either with ashes or clinkers. Sure as ever it was windy down he would go and scrape into his basket all the ashes he could find," and these ashes blew in at the windows, and under the doors, and filled every place and every thing, even the oven was not safe. Poor cook declared "she could not go anywhere, open a cupboard or drawer, without meeting with ashes. It was a very Pharaoh's plague." The housemaid said, "Sure as ever Saturday afternoon came, and the yard was scoured out, and no little doing it took, and all cleaned up, then they would bring either coals, or cinders, or

slack," and these had to be put down very near to the front-kitchen door. And certainly a great deal of fuel was consumed, for the old man burnt away at the coal, and often said he had the best fire for miles round; he had no thought about him, for the hotter the sun shone the more and more he put on the fire. It had no rest, no peace with him. When spoken to about it he took offence, and never made his appearance again. Then, too, all the dust, and dirt, and spoiled dinners, and mischief that happened in the house, were put down to the greenhouse. Aunt Margaret, who had lived with uncle Tetley many years, ever since his wife died, and had brought up Janet and Kate, was very much put out; she often said she would go away before the time of ruin came, for that vinery would prove to Herbert, if not to all of us, a very white elephant.

Things wore on in this uncomfortable way until December, when one evening just as it was growing dark, Kate came running across to our house in great trouble, exclaiming, "Oh, Maud, what shall we do? all our plants will be killed. The thermometer in the garden is standing below 30°. The greenhouse fire is out, the old man has not come, and there is no one to make it. What shall we do? Papa told the housemaid to see after it, and she walked straight up-stairs to Aunt Margaret, and gave notice to leave. The kitchen girl would have tried to make it, but cook kept her very busy, and would let her have neither fire nor wood. What must we do?

"We must go and make it, Kate. We have more plants than we can afford to lose."

"I wanted to do it, but Aunt Margaret said it was not a lady's work, and if I were bringing myself down to minding a furnace fire, it was a pity Papa had spent so much on my education."

"Never mind that, we must go."

So we pulled on our hoods, ran through the two gardens as fast as we could, tucked up our sleeves and flowing skirts, and commenced operations. It was a good thing Uncle Tetley was so fond of herrings, but for the old boxes I do not know what we should have done; with the help of a huge blocker they were soon chips, that day's *Times*, found by chance near at hand, for we dare not go into the house, was thrust into the long, narrow grate, wood after wood piled upon it, then coals, then a light put to it, and all shut up close, fire-door, and ash-door, and so close did they fit, not a ray of light reached us as we sat on the lowest step of the stairs in the splendour of a twenty-four dip candle. Our white petticoats were soiled, and no wonder, for dust from the coals, and ashes, and soot, and spiders' webs, lay thick upon the walls, and the flue-doors, and in every corner. Three cell-like cellars opened out before us, for coals, cinders, and slack; into their gloomy darkness we dare not penetrate, they lay beyond the reach of our poor rush-light.

"It does not make a bit of noise, Kate, it must be going out."

So we opened the door and tried to look in, we could see nothing for the volumes of smoke that rolled out, half blinding us. This soon cleared away, for our fire would not burn, was dying out as fast as it could, smothered, though we knew it not.

All this time Master Frost came on, nearer and nearer; already he stood close by, working fast with his icy tools, carving strange fantastic figures on the glass, roof, and window, travelling round every square of glass, seeking any point however small for entrance; and then we knew full well, ruin and death, death and ruin we could not avert, must follow.

Again and again we tried to make our fire burn, thrusting in wood and paper and coal, and found out after an hour's toil that it would burn if we would let it have air. All by chance we left open the ash-door, then crackling and sparkling up went the fire with a roaring noise, as if to make up for lost time. Once more we sat down upon the stairs to watch and wait, no use in going up into the vinery, and so letting in great gushes of frost. The sun had shone upon the house all day, and it had not been opened, so the chance was it might contain enough heat to set at defiance, for an hour or two at least, the outside cold.

What beauties we were to be sure! Our elbows sooted, our arms grimed, as if some Indian chief had painted us for his especial pleasure. And, then, what hands we had! Kate declared "we should have to take in washing for a month before they were clean."

When they knew all about it, how Uncle Tetley laughed, and Aunt Margaret scolded, and Cousin Herbert said, "It must not happen again, something or other must be done." And yet what? for Aunt Margaret would not have a man hanging about the house, doing nothing two-thirds of his time, and then to have a regular gardener, why that would run away with more than £1 a-week, and to get a man or boy for an hour or two each day was just impossible; and then, too, Cousin Herbert wanted to manage the Vines—have them all his own way. And we wished to have our plants all to ourselves without a gardener to knock them about, and call them his, and to look cross when we cut a few flowers for our pastor's wife. So we talked about it at home, and at Uncle Tetley's, and were doing so one day, when Mary, the cook's help, a young girl from the country, came into the room with some coal; in her eagerness to speak, she dropped her box down with a great noise, saying, "I am sure I could manage that fire if you would teach me, Miss Kate."

So we set to work under Cousin Herbert's directions, receiving our lessons night and morning, and duly imparting the same to Mary, who acted under our supervision. A month and the fire was managed to everybody's satisfaction. There might be mistakes sometimes that could not be prevented; but we kept the frost at bay. Cousin Herbert always made up the fire safely for the night, that was his portion of work, his duty.

My own opinion is, many a young girl would manage a greenhouse fire as easily as she does one in her kitchen grate, if she were rightly taught. Kate had often called the little boiler-house the darkest, dirtiest, and most badly-planned one in the world. It soon changed under Mary's management, brush, and broom, and lime, making short work of ashes, and coal dust, and spiders' webs, and we could walk down into it without soiling our feet, or having to take extra care of our skirts.—Maud.

(To be continued.)

[Heartily, very heartily, the Editors respond to your good wishes. They thank you for your kindly greeting, and wish for you and yours a very merry Christmas and a truly happy New Year. *Their* Christmas would be merrier, and *their* New Year happier, if they knew more of your name than "Maud," and more of your whereabouts than is revealed by the post-mark.]

POTATOES.

In page 462, Mona's Pride is highly eulogised, in the following page it has a poor character. Mr. Myers, an experienced cultivator, in his advertisement last spring gave it a high character. I have found it not earlier than the Ashleaf, and so inferior in flavour and liable to disease as to be worthless. What, then, can we say to opinions so equally balanced? I have been for many years a sort of amateur cultivator, trying all or nearly all the varieties to test their qualities, merely to gain a knowledge of the sorts best adapted to the wants of my family, and have come to the conclusion, that except the Ashleaf and two or three other early sorts, there is scarcely a variety that can be safely recommended for all soils and climates, as they differ to so great an extent according to the nature of the soil, and, I may add, of the season. In 1862, 1863, and 1864, I imagined that my choice was fixed for life—Ashleaf forced for spring, in the open ground the same sort for summer, the Lapstone for autumn up to Christmas, and the King (Hudson's), for early spring. They were all perfect, and when steamed and brought to table with their jackets bursting, one often declared that one could dine off them. Alas! that this is for the present passed away.

In 1865, the hines of all but the very late sorts died off in August from the disease, but as they had finished their growth and the tubers were particularly clean and sound, I thought but little of it. Towards the end of the month the tubers of the Royal Ashleaf became too firm and had lost their flavour. As these had been our grand resource for the summer and early autumn and had never failed, we were loth to credit the fact. It was too true, however, and so we turned to our autumn favourite, the Lapstone, steamed and served as usual To our discomfort we found the flesh yellow, firm, and flavourless—no bursting of jackets—so for the first time for many years paring and boiling with salt, and drying-cloth *secundum artem*, was resorted to. They were drier, but still flavourless, and this lasted all through the winter, not only with the Lapstone, but with the King and Pink Fluke, both hitherto so good, and thus two unsatisfactory Potato seasons have nearly passed; for this season they are exactly of the same character —there is no satisfaction in eating them. I may add, that in 1865 I planted for trial eight or ten of the popular sorts of Kidney Potatoes, all of which proved as unsatisfactory as my hitherto above-mentioned favourite kinds. The question is, Is this disagreeable change to be permanent? I hope not, but

I am thinking of a change, and intend to try one or two of the white floury kinds, which I have up to this time considered deficient in flavour. I am, however, firmly convinced that soils influence the quality of Potatoes to an extent greater than has ever been calculated: hence the necessity of a trial before any variety is planted to a large extent. I may add, that I changed my seed of the Lapstone last spring. Its produce is, if anything, inferior to that from my own seed. In 1865, "The Boon" was as described by "D.," page 463, and the Silverskin but little better.

The "disease" has this season assumed a curious phase. Here formerly if Potatoes were taken up early, just before being ripe, and exposed to the air for a few weeks, they always proved sound and healthy seed. This season the converse of this has taken place. A large quantity taken up at the end of July and laid on the surface of the soil for two or three weeks till they were perfectly green, are now a mass of rotteuness, while those taken up some weeks later and stored in the same place are comparatively sound. With four early kinds—Early Ten-Week, Coldstream Early, Shutford Seedling, both free-bearing excellent early sorts, and Early May, all planted on the same day, and all taken up at the same time fully ripe, and free from the disease at the time, it has been more violent and destructive than I ever remember. They were spread on the surface of the soil for a week or two till green, then placed in shallow baskets, which were placed in a shed exposed to the sun and air. In October, on examining them previous to storing them in the cellar, two-thirds of them were found covered with patches of mould and perfectly rotten. The state of the atmosphere which, as is well known, was constantly overcharged with moisture, must have encouraged the growth of the fungus which so mysteriously destroys one of our most valuable products. Hitherto exposure has acted as a preventive, but this season apparently as an incentive to disease. Thus are science and practice alike baffled, and we must bow to that which no man can comprehend, the will of the great Ruler of All.—Solanum.

HYGROMETERS.

We can generally learn from any horticultural work the temperature which will suit the plants which we wish to cultivate; but we seek in vain for any definite directions as to the degree of atmospheric moisture which they require. It was, therefore, with much pleasure that I lately saw in a contemporary a recommendation from Mr. D. Fish, that during the season of active growth the wet bulb should stand 4° below the dry, and during the ripening period from 10° to 15°.

Observations upon this subject have been few, not only because gardeners in general have not been sufficiently alive to its importance, but also because of the trouble of keeping in working order a wet-bulb thermometer, and the difficulty of finding for it a suitable position in the house, sheltered from the sun and cold currents of air. Some time ago I tried a cat-gut hygrometer. I spliced together two A violin strings, and thus got a length of about 8 or 9 feet, which being passed over a brass pulley took up only 4½ feet. One end was fixed, and to the other was attached a quarter-pound weight. It acted, it is true, but it did not respond sufficiently quickly to increased moisture to be of any practical utility.

Two years ago I had an illustration of the importance of the subject. One side of an orchard-house was filled with Figs ripening off their second crop; the other side was filled with plants of Physalis edulis. There was no syringing, but the Figs were poor in flavour. It occurred to me that as the Physalis was a thirsty plant, requiring a large quantity of water at its roots, the air might be too damp, so I removed the Physalis, and the Figs became perfect.

It is possible that some cases of Peaches not ripening well in orchard-houses may arise from some mismanagement as regards moisture either in the air or at the roots; but it also may arise, as your correspondent "G. H." thinks, from a deficiency of heat. In my own case, this, I believe, is the cause why so few of the Peaches in an unheated house, though well swollen and well coloured, are really sweet. The house has no sun after three or four o'clock, and there are too many tall trees near it. In that exceptionally warm year, 1858, the Peaches were exceptionally good, and all that could be desired.—G. S.

Mildness of the Season.—On this shortest day of the year, fine bouquets of Primroses may be gathered in our neighbourhood, and in my garden (on a sunny bank, it is true), several plants of Keens' Seedling have fine trusses of bloom. Besides this, in the open garden, but in a sheltered spot, a small Hampton Court Vine has not yet lost its leaves, which are at this moment as green as they were at midsummer.—H., *Ventnor, I.W.*

ICE-KEEPING.

Should we be deficient of ice this season as we were last, I think the following account of ice-keeping may be worth a place in your columns.

I was not able to take any ice from the ponds here last season, till the first and second days in March, and then it was only about 1½ inch thick. As we had a fall of about 2 inches of snow on the 27th of February, I set a man to work to put together in a ridge a quantity of snow, by pushing it up with the back of a wooden rake, and on the 1st and 2nd of March, I filled our ice-house with ice and snow. I began with ice, putting in three cartloads of ice, and then one load of snow. I levelled the ice before putting on the snow, spread the latter over the ice, and rammed all well down. For this purpose I used a cylindrical piece of wood 9 inches in diameter, and 14 inches long, into one end of which I had made a hole and driven in a plain stake for a handle, so that a man could stand upright, and, taking hold of the handle with both hands, walk over the ice and snow, and ram all well down. Two or three men can ram each layer well in about fifteen minutes. I kept on in this way till I had filled the well, which is one of the old-fashioned barrel-shaped wells, 16 feet deep, and 12 feet wide at the middle. Now, all gardeners who are in the habit of storing ice, know within a little how much ice and snow I had in this well. Carts vary much in size; twenty-eight of our cart-loads will fill this well, if the ice is thick enough to build up a little above the sides of the cart; but when ice is very thin we cannot do so. I have stored away ice in wells and stacks for the last thirty years, and I never knew ice keep so well as the snow and ice have done. I took from the well no less than twelve bushels of ice every week for three months, and used some before for dinner-parties, so I have since, and now there is in it more than 2 feet thick of ice, and it has not wasted more than 15 inches from the side walls. I took some ice from this well yesterday (December 18th), and no one would know that there is snow amongst it. The ice is rather rough-looking, but it is all ice now.

I do not think we shall be so short of ice this season. I think we shall have plenty in January; but if the ice be 3 inches thick when I fill the well, I will put snow with it, if I can obtain it clean, but at present we have a great many leaves on the park.—C. Short, *Flixton Hall Gardens.*

VINES AND VINE BORDERS.

So much has been written by practical men about the formation of Vine borders, one recommending them to be 5 feet deep, another 3 feet, whilst another grows full-sized, high-coloured, and fine-flavoured Grapes without any prepared border, that an employer of labour who wants to lay out his money to the best advantage is perplexed to know how to proceed.

I do not think the five-feet-deep borders are the best for growing Vines. Some years ago I had the management of three vineries where the Vines were planted in such borders, and in all three houses the Grapes were liable to shank. The roots of the Vines had a tendency to go straight down to the bottom of the borders in search of food instead of spreading out in a horizontal direction as they ought to have done. I have dug these borders over, and never found a root near the surface. In the first house which I will mention were planted Black Hamburgh, Red Frontignan, and Chasselas Musqué; the two latter were grafted on the Black Hamburgh, but even then the Grapes were liable to shank as soon as they were ripe. The Black Hamburgh, being of a hardier nature, succeeded better.

In the Muscat-house matters were much the same. Sometimes the stalk of a single berry, sometimes the stalks uniting several berries, and in some cases whole shoulders, would shank without any apparent cause. In this house the Muscat of Alexandria Vines were the least liable to shanking their fruit, whilst the Canon Hall Muscat on its own roots was the most so, and the flesh of this sort had not that degree of firmness which it acquires under the best cultivation. This is a Grape

seldom seen in perfection, although one deserving of extensive cultivation. It is, I think, very much improved by being grafted on the Black Hamburgh. The best fruit of it which I have seen was from Vines grafted on that sort, the border being composed mostly of the natural soil of the garden.

In the third house were planted Black Hamburgh, and, I think, Royal Muscadine on their own roots. This house used to do better than the other two; but I always thought the Vines would have succeeded still better if the roots had not gone down so deep, and further experience has confirmed me on that point.

With regard to the next Vines that came under my notice, the borders were what would be called shallow—that is, from 2 feet 3 inches to 3 feet deep, and they were made at first about half the width they were ultimately intended to be. The soil was taken out to the required depth for about 6 feet wide on both sides of the front wall, so that there was a prepared border on each side of the wall, one outside and one inside. The soil was composed of the top spit of an old pasture, without the addition of manure of any sort. The Vines were planted on a ridge raised about 9 inches above the floor line, a single rod was taken up from each plant, and nearly in every case the Vines reached the top of the house the first season, making strong short-jointed wood, and well ripened, without the assistance of artificial heat, even in the case of the Muscats. In the following season they were cut back, the rods being left from 8 to 16 feet in length; and being carefully started in the spring they broke regularly, showing in most instances three bunches at each joint. Of course the greater part of these were removed at once, leaving in the end only from three to six bunches on each Vine, so that they ripened these well, and again made strong growths. They were supplied during the growing season with liquid manure, but not in large quantities, about three or four times in the course of the season. Next year the Vines carried a good average crop of from six to twelve bunches each. I did not see any of them weighed, but I judged some of the Black Hamburgh bunches weighed upwards of 3 lbs. each; they were beautifully coloured and of excellent flavour.

I will now notice the state of the roots in these vineries. In forking the borders over in order to add some farmyard manure, the roots were found to have spread in a horizontal direction to the outside of the prepared border, quite close to the surface. If I had had the sole management of the borders, and if the materials could have been obtained, I would have proceeded in this way: I would have thrown equal quantities of fresh horse-droppings and cowdung into a heap together; they would soon have heated, and if the cowdung was wet, as it sometimes is, it would have dried in the course of fermentation. After the heat was gone—(the heap ought not to be allowed to heat violently; if it do so it should be spread out on the floor of the shed. I presume, of course, that it is in a place where the rains will not reach it)—to every two barrowloads I would have added one of turfy loam, and surface-dressed the Vines with the mixture instead of digging amongst the roots. The repeated waterings would have washed the nourishment down; and the manure being kept on the surface, the roots would be near it too, and there they would be better able to feed the Vines than if they were down at the bottom of five-feet borders, and that is where they will go, especially if bones or other manure be added to the loam when the borders are made.

Since then I have had the charge of forming the borders for two vineries, and I was prevailed upon to add some manure to the loam when the borders were made; a small quantity of lime was also added, and the Vines under the same treatment have not done so well as in the case when only the turfy loam was used. The borders were rather more than 3 feet deep, and scarcely any roots are to be found near the surface. I have therefore come to the conclusion that turfy loam without the addition of any manure the first season is the best material of which to form a Vine border. There is plenty of nourishment to be found amongst the decaying roots of the grass the first season, and manure can always be added either in the liquid form or by means of surface-dressings.

In the preceding observations I have simply recorded the results of my own experience. When I say that borders made without the addition of bones or other manures are the best I do not intend to assert that borders formed in the other way will not answer. I have no doubt they will, otherwise practical gardeners would not be found to advocate them; but I hope our amateur friends will not be disheartened because they cannot go to the expense of having flagstones and other expensive materials buried at the bottom of the border, because I am fully convinced that they are not necessary.—J. Douglas.

PSIDIUM RADDII.

I wish your correspondent who signed himself "Raddii, *Peterborough*" (December 26, 1865), would state whether the above fruit is superior in quality to P. Cattleyanum, and whether it is equally hardy. Of the latter there are two varieties, the fruit of one being spherical, of the other somewhat Pear-shaped. The nurseryman of whom I bought my plant assured me that it required a stove, and it certainly came out of one, but it soon accommodated itself to a slightly-warmed orchard-house, and fruited abundantly. On two occasions it stood a temperature of 36° uninjured. The fruit seemed to me decidedly inferior to the larger tropical Guavas, so I gave up growing it.—G. S.

HOT AIR FROM A KITCHEN RANGE.

"Rusticus," in the Number for December 18th, inquires how he can utilise a fire situated in the kitchen, of which the wall containing the fireplace forms the side of an out-building. This he can easily accomplish by passing an ordinary piece of gas-pipe, bent at two right angles, through the fire, so as to let one end project into the room towards the hearth, the other into the out-building. The heated air in the intermediate part rises into the out-building, and the air rushing in from the room to supply its place passes in its turn through the heated tube and is delivered warm into the out-building. This simple plan can also be advantageously used to increase the heat of ordinary stoves, whether in the greenhouse or hall.—J. M. F., *Streatham*.

ENTOMOLOGICAL SOCIETY'S MEETING.

The December Meeting of this Society was held at Burlington House on the 3rd inst., the President, Sir John Lubbock, F.R.S., in the chair. Amongst the donations to the Society's library received since the last meeting were the Memoirs of the Linnean Society of Normandy, the "Hymenopterous Memoirs" of M. Sichel, &c. Six new members were balloted for and elected.

Mr. W. F. Evans, F.L.S., sent for exhibition a number of insects, chiefly Beetles (especially the beautiful Pyronota festiva, belonging to the family Melolonthidæ), which had been found amongst wool imported from New Zealand.

Mr. Stainton exhibited living specimens of Gracillaria scalariella, bred from larvæ found at Cannes in the South of France, mining the leaves of Echium vulgare, communicated by M. Milliere; also some flat pouch-like galls, obtained from Mentone, near Nice, formed on the leaves of Pistacia lentiscus, apparently by Aphides, but which were inhabited by a Phycideous larva.

Mr. Inuson exhibited a box of insects collected by Mr. W. Hume in the vicinity of Rio Janeiro.

Mr. Daer exhibited a chrysalis of the common Tortoiseshell Butterfly, from each shoulder of which depended a slender filament nearly as long as the chrysalis itself.

The Secretary communicated a notice on the employment, in tropical countries, of mahogany timber of Western Australia, that kind of wood not being subject, from its peculiar qualities, to the attacks of White Ants, which are so destructive to all other woodwork in hot climates.

Dr. Sharp exhibited Stenus major, a species of Staphylinidæ new to the British lists, taken at Southend.

Professor Westwood communicated a biographical notice of the late Mr. S. Stone, whose collections of insects, nests of Wasps, &c., as well as his antiquarian collection, had been presented to the museums at Oxford. He also exhibited a number of specimens of the Gipsy Moth, Liparis dispar, reared by Mr. Briggs, of St. John's College, Oxford, showing the variations which had resulted from feeding some of the individuals exclusively on White Thorn and others on Elm. The females of the latter set were invariably crippled, and the whole of them sterile. This exhibition gave rise to considerable discussion. Professor Westwood also communicated a letter from Edward Holdsworth, Esq., of Shanghai, containing a description of the caterpillar of the beautiful Moth Bombyx Selene.

The discussion, commenced at the preceding meeting, on Natural Selection and Mimetic Analogies, was resumed, and continued at great length, being participated in by Dr. Sharp, Messrs. Bates, Belt, Stainton, Weir, Wallace, McLachlan, Professor Westwood, and the President; during which the immunity of the Heliconian Butterflies in South America from the attacks of birds (suggested by Mr. Bates as a cause of the mimicry which he assumed to have been adopted by

certain species of Pieridæ), was confirmed by Mr. Belt, who stated that he had observed, for a considerable period, a particular nest of a pair of insectivorous birds at Maranam in Brazil, and had noticed that although they captured other Butterflies, Dragon Flies, &c., in great numbers for the food of their young, not a single Heliconian was taken, although flying about slowly in great quantities at the time, and close to the spot. Mr. Stainton also stated, in proof of the distaste of birds for certain species of insects, that on one occasion he had captured a quantity of Moths flying round a lighted lamp, the whole of which, with the exception of a single Spilosoma Menthastri, proved to be the common Noctua exclamationis. On discovering this next morning, the whole were thrown to some young turkeys, which greedily devoured them, except the Spilosoma, which they could not be prevailed upon to touch; and Mr. Weir stated that he had offered the larvæ of the same species of Spilosoma to some birds which he had kept in an aviary, and that in like manner they had refused to touch them.

Mr. McLachlan read two papers, entitled, "A Description of a New Genus of Hemerobiidæ," and "A Description of a New Genus of Psocidæ."

New Orchid.—An Orchid has lately flowered in the collection of Mr. Thomas R. Tufnell, at Spring Grove, which is pronounced by Professor Reichenbach to be an entirely new species of Epidendrum. Herr Reichenbach proposes that it shall be called Epidendrum eburneum, in consequence of the ivory-like appearance of the flower. The plant has been figured by Mr. Fitch, for the authorities at Kew, and will appear in the "Botanical Magazine" shortly.

BARLASTON HALL,

The Seat of Ralph Thomas Adderley, Esq.

Barlaston Hall lies about five miles south-east of Newcastle-under-Lyme, five miles south of Stoke-on-Trent, and half a mile north of Barlaston station on the North Staffordshire Railway. The village of Barlaston is delightfully situated near the summit of a high acclivity on the east side of the vale of the Trent.

The Hall is a handsome mansion near the north end of the village, and, viewing it in the distance, appears well sheltered with forest trees. I passed into the grounds through a plain entrance-gate by a commodious lodge. The carriage-drive to the house is through a long avenue of Limes, which skirts the drive on either side, and terminates on the east side of the mansion. A footpath to the right, a little beyond the lodge, leads to the kitchen gardens, and arriving at the frame-ground, I observed various houses, which I will notice in the order I passed through them.

The first is the fernery, 52 feet long, 15 feet wide, and 16 feet high; the Ferns are interspersed with a few stove plants, such as Marantas, fine-foliaged Begonias, Aspidistra elatior fol. vittatis. &c. On the left-hand side of the house is a raised rockery, and the fairy Maiden-hair and other Ferns growing among the stones look very attractive. At the farthest end of the house is a fine specimen of Cyanophyllum magnificum, with luxuriant foliage of this season's growth. Up the pillars, and suspended from the roof with graceful ease, are plants of Passiflora alata, and Thunbergia Harrisii. The next house is 39 feet long by 10 wide, in two compartments. The first was for early Cucumbers; the plants were just coming into bearing, and and looked very healthy. This house promised to be very useful for a good winter supply.

In close proximity is a late vinery. The varieties of Grapes cultivated include White Tokay, Lady Downe's, West's St. Peter's, and Black Morocco. The fruit was all gathered, and underneath the Vines was a miscellaneous collection of plants.

Behind the vinery, with a north aspect, is a house in which are wintered large Aloes and Orange trees, which are interspersed on the terraces and in the flower garden during the summer months. We now enter a span-roofed stove, 40 feet long by 10 wide. Here were many things that attracted my attention, but the visit being hurried, I can only mention a few of the most conspicuous plants that deserve a place in every collection.

Among the most beautiful plants with fine foliage were examples of Alocasia metallica and A. Lowii, with their lustrous, bronzy, shield-like appearance; A. macrorhiza variegata; Gesnera chromatella and G. refulgens, with their curious markings and velvety foliage, admirably adapted for dinner-table decoration—the light playing on the brilliant crimson hairs, with which the latter is well studded, makes it an object of great attraction; Croton angustifolium, pictum, and variegatum; Dracæna Cooperi and ferrea; Gymnogramma peruviana; also a few Orchids, Oncidium flexuosum in bloom being very pretty. In cold frames there were useful collections of robust Cinerarias, herbaceous Calceolarias, and a lot of nice Cyclamens just expanding their charming blossoms.

I then left the frame-ground, and entered the kitchen garden, where neatness and good order markedly predominated. Near to the edges of the kitchen-garden walks are nice symmetrically trained pyramidal Pears. Across the centre of the kitchen garden, ranging east and west, is an arched trellis of iron wire. To this trellis are trained Pear trees, which in summer must make this a very pleasant promenade. In the different quarters were good supplies of winter vegetables, and beds of Celery with three or four rows in a bed.

On the south wall is a range of glass upwards of 200 feet long, divided into six compartments. Beginning at the west end of the range, the first division is an early Peach-house, started a few days before my visit (November 21st). It is 60 feet long, 18 feet wide, 15 feet high at the back, and 4 feet high in the front; rather a large house to start so early. It is furnished with a neat, narrow, slate path 2 feet wide, and the trees are trained, one row against the back wall, and another row to an arched trellis in front. They were in excellent condition, and promised well for a large supply of fruit. I have seen a Peach-house on the same principle at Thorneycroft Hall, in Cheshire, with the front trellis in the form of an arch; it economises space, and admits a greater amount of light to the lower part of the trees on the back wall.

The next house is a vinery 27 feet by 16, exclusively planted with Black Hamburghs. Going out of the vinery we come into the conservatory, which is nearly the centre of the range, and opens into the central walk of the kitchen garden.

Several large greenhouse plants are turned out into the border, and so luxuriant are they, that their heads nearly protrude through the roof. A large Habrothamnus elegans would soon be smothered with hundreds of racemes of crimson flowers. Brugmansia Knightii had just done blooming. I often wonder why we do not more frequently meet with this gorgeous autumn-blooming useful species in general collections of greenhouse plants.

Beyond the conservatory is another vinery, that had been recently planted with a mixed collection of Vines. It is 31 feet long by 16 feet wide. Stepping out of this house we enter another Peach-house, 27 feet by 18, which is started about the early part of January. The last house in the range is a greenhouse 32 feet by 18, with plants in bloom brought from the other houses, and even at the time of my visit, when flowers were scarce, it was a glorious mass of floral beauty. I observed as the most conspicuous in bloom, dwarf examples, about 8 inches high, of Poinsettia pulcherrima, very effective, and one of the most useful plants at this season, either for the decoration of the stove, or for conservatory and greenhouse embellishment. There were also in flower Chrysanthemums, Epiphyllums, Fuchsias, and Primulas, with a sprinkling of fine-foliaged plants.

In the pleasure grounds, the first attractive objects were two very large herbaceous borders on each side of the walk, more than 200 feet in length, planted with choice Phloxes, Pentstemons, Antirrhinums, &c., and near to the edge of the beds were rows of Snowdrops and Dog's-tooth Violets. These beds are screened from the main walks by large evergreens and other trees of varied foliage. Passing on through a serpentine walk, and across to the carriage drive, I was brought to a most delightful retreat for a hot summer's day. On the left-hand side of the walk are a number of raised flower-beds; on the opposite side a rustic cottage covered with Honeysuckles, Clematises, Roses, and Ivy.

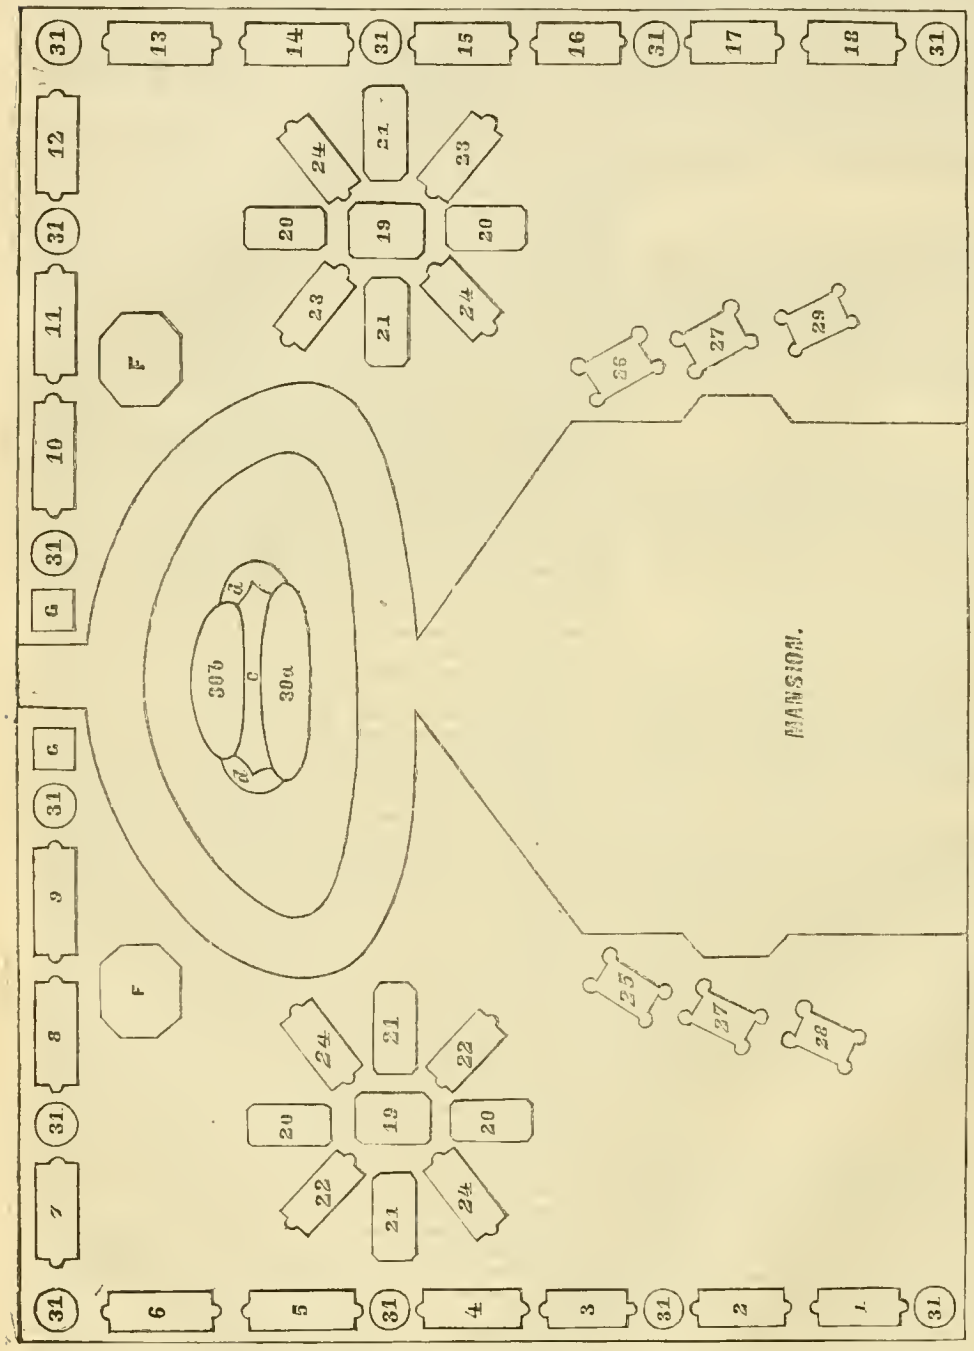
Through an Ivy arcade near to this spot, in a secluded little dell, is the hardy fernery and rockery. Among the Ferns were Lastrea Filix-mas cristata, Osmunda regalis, Polypodium vulgare, Polypodium dryopteris, and many others, natives of the district.

From thence I passed on by the Rose garden. All the trees are named, and most of the popular varieties may be found amongst them. As I passed along this walk my attention was arrested by immense clumps of Rhododendrons 12 or 14 feet high. Better examples of this noble flower it would be difficult to find. It is scarcely possible to conceive their beauty in the months of May and June.

Ascending a flight of steps on to the terrace, we came in front of the mansion. The front is to the west, and the terrace

extends to the north and south sides. It is bounded on each side by an ornamental balustrading, and the views from this terrace are very extensive and varied. The park falls with a gradual descent to the lake. Beyond the lake is the North Staffordshire Railway. The railway is skirted by the Mersey canal, and beyond that, through the valley, the river Trent winds along. In the distance may be seen the snug little hamlet of Trentwell, and the large wood at Trentham; while to the right on a bright day are distinctly seen the towns of Stoke-on-Trent, Burslem, and Tunstall.

The accompanying is a plan of the flower garden. The beds are surrounded by a beautifully dressed stone edging about 3 inches high, within which the beds are raised above the grass. The beds, *a a*, are raised about 2 feet, and encircled



SOUTH SIDE—WALK 104 FEET LONG, 10½ FEET WIDE.

SUMMER PLANTING.

1, Pelargonium Stella. 2, Calceolaria amplexicaulis. 3, Verbena Purple King. 4, Pelargonium Flower of the Day. 5, Verbena Ariosto Improved. 6, Pelargonium Golden Chain. 7, Lobelia speciosa. 8, Verbena Mrs. F. G. Culey. 9, Pelargonium Rubens. 10, Pelargonium Cerise Unique. 11, Cineraria maritima. 12, Senecio elegans. 13, Pelargonium, Ivy-leaf White. 14, Verbena Foxhunter. 15, Verbena Paxtoni. 16, Verbena Lady Cotton Shepherd. 17, Tropæolum, double. 18, Asters, Dwarf Chrysanthemum-flowered. 19, Centre row of Perilla nankinensis. 2nd row, Calceolaria Aurea floribunda. 3rd row, Lobelia speciosa. 4th row, Cerastium tomentosum, an edging all round. 20, Ageratum. 21, Verbena Mrs. Holford. 22, Pelargonium Trentham Rose. 23, Ditto Tom Thumb. 24, Calceolaria Aurea floribunda. 25, Pelargonium Crimson Ivy-leaf. 26, Verbenas, mixed. 27, German Stocks. 28, German Asters. 29, Pelargoniums, mixed. 30, *a a*, Ditto Gem of Roses. *b b*, Ditto Helen Lindsay. *c c*, Chrysanthemum coronarium album plenum. *d d*, Pelargonium Baron Hugel. 31, Mignonette, Humea elegans in the centre. F F, Fountains. G G, Vases filled with Pelargoniums in summer.

The following is the present arrangement of the beds for spring decoration:—

1 and 18, Crocus, yellow.
2 and 17, Dog's-tooth Violet.
3 and 16, Crocus.
4 and 15, Tulips.
5 and 14, Crocus.
6 and 13, Tulips.
7 and 12, Crocus.
8 and 11, Tulips.
9 and 10, Crocus.
19, Hyacinths.
20, Alyssum saxatile.
21, Tulips, Rex rubrorum.
22 and 23, Myosotis palustris.
24, Pansies.
25 and 26, Pansies.
27, Crocus.
28 and 29, Bellis (Daisy).

with ornamental stonework. Through the kindness of Mr. Myatt, the head gardener, I snbjoin a list of the plants with which the beds were adorned during summer, and also a second list, giving a description of what the beds are now filled with for spring decoration.

In conclusion, all that I saw at Barlaston was very praiseworthy. The extensive grounds were in good keeping; each department gave commendatory evidence for Mr. Myatt and his assistants, from whom I received the utmost courtesy.—QUINTIN READ, *Port Hill Gardens, Burslem.*

NOTES AND GLEANINGS.

Those of our readers who have rooms and conservatories with a north aspect, or which are overshadowed by other buildings, will be aided by the following note of a suggestion by Sir David Brewster:—"If, in a very narrow street or lane, we look out of a window with the eye in the same plane as the outer face of the wall in which the window is placed, we shall see the whole of the sky by which the apartment can be illuminated. If we now withdraw the eye inwards, we shall gradually lose sight of the sky till it wholly disappears, which may take place when the eye is only 6 or 8 inches from its first position. In such a case the apartment is illuminated only by the light reflected from the opposite wall, or the sides of the stones which form the window; because, if the glass of the window is 6 or 8 inches from the wall, as it generally is, not a ray of light can fall upon it. If we now remove our window and substitute another in which all the panes of glass are roughly ground on the outside, and flush with the outer wall, the light from the whole of the visible sky, and from the remotest parts of the opposite wall, will be introduced into the apartment, reflected from the innumerable faces or facets which the rough grinding of the glass has produced. The whole window will appear as if the sky were beyond it, and from every point of this luminous surface light will radiate into all parts of the room."

—— We have received from Messrs. Lucombe, Pince, & Co., of Exeter, a bunch of that admirable Grape, Mrs. Pince's Black Muscat, which was ripe on the Vine *twelve months ago*. We need hardly say it is now in the state of raisins, and these are as fine, fleshy, and delicious as the finest imported Muscatels. We take this opportunity of stating that Mrs. Pince's Black Muscat is one of the most valuable acquisitions in the way of Grapes which has been introduced for many years. Imagine the delicious but miffy old Black Muscat of Alexandria, with a robust constitution, a thick, stout, sturdy, berry-stalk, a tough membranous, though not thick, skin, and with the property of hanging till the sap rises again, and you have Mrs. Pince's Black Muscat.

WORK FOR THE WEEK.

KITCHEN GARDEN.

We have but little to add to former directions in this department. The principal routine of business to be performed at this season is thorough draining, opening, clearing out, and repairing old drains, and making new ones, altering walks and fresh casing them with some good hard materials, the edgings having first been evenly made up. There is nothing in a kitchen garden which has a more neglected, dilapidated appearance than uneven, weedy walks, with gappy, overgrown, or irregular Box or other edgings. The wheeling out of manures on spare borders and quarters, and trenching, must be proceeded with, and all possible speed should be made with these operations in suitable weather. Hoeing and surface-stirring amongst all kinds of progressing crops must be performed in fine days. By this practice the mutilation and destruction occasioned by obnoxious insects and their larvæ are to a great extent prevented. We should never hear of the destruction committed by slugs, snails, wireworms, or other vermin to any considerable extent if such a system were faithfully carried out. Abundant preparations for the coming spring must be made in this department. A stock of garden mats must be procured for covering-purposes, and a mat or two cut up, tied in bunches in two classes, and hung up ready for summer use. Plenty of shreds for wall trees will require cutting, and the old ones should pass through the ordeal of boiling water. Here, too, the preparation of labels for dating and naming crops must proceed, and the seed-drawers should be thoroughly examined, cleaned out, and the old seeds dated and classified, in order that their relative value may be readily known. The new seeds will, of course, want arranging. Above all, a scheme of cropping, based on a judicious rotation, should be laid down forthwith. Broccoli, Celery, Carrots, Endive, Lettuce, Parsley, and other needful articles, should be protected in due time from frost.

FRUIT GARDEN.

Figs against walls will require some protective material placed over them in the midland and northern counties. This, indeed, has been a favourable autumn for performing operations in the fruit department. We hope that all speed has been made. It may be said that the ground has been damp under foot for standing to prune and nail; but surely a dry board to stand on could be obtained. It should always be cleaned and put to dry in the tool-house, so as to be in readiness and comfortable for the feet again by the next day.

FLOWER GARDEN.

The weather is still exceedingly favourable for the execution of alterations or new work, and it will not be the fault of the weather if such work be not finished in good time this season; but we know from experience that it is in many cases easier to commence such operations than to know when or where they will end, and we would merely recommend here that every possible dispatch should be used to complete all such operations as speedily as possible, in order to have the hands at liberty for the regular work, which, save in a few favoured cases, will soon require all the labour that is allowed. If not yet done, the leaves should be cleared up and the shrubbery borders lightly forked over to give them a fresh appearance. Lawns and gravel walks must be frequently rolled, so as to keep them firm and smooth. Those who purpose planting in the spring—for many persons still retain the notion that planting can be done in spring with greater certainty of success than at any other season—should lose no time in preparing the ground by trenching, or whatever may be deemed necessary for the plants. On light sandy soils there will be no particular necessity for making the pits at once; but, however friable the nature of the soil may be, it will be all the better of exposure for a month or two to the action of the weather. Where Rhododendrons are grown in masses and exhibit any indications of having exhausted the soil, a top-dressing of cow-manure, well decomposed, some 3 inches deep, and extending as far as the roots, should be applied at once. This will strengthen the plants for flowering, prevent rapid evaporation in summer, and keep the ground cool and moist, which is essential to the well-being of this handsome tribe of plants.

GREENHOUSE AND CONSERVATORY.

Attend carefully to valuable pot specimens of hardwooded plants, which it may be necessary to winter in the conservatory, for many of these are very impatient of fire heat and a confined atmosphere, and ought, therefore, to be kept as much out of the way of its influence as circumstances permit. Such plants should be placed near the glass, turning them partly round every week so that all their parts may be equally exposed to light; and admit fresh air on every favourable opportunity, but carefully avoid cold cutting winds, which, if allowed to blow through plants just after they have been kept close with fire heat for some time, are sure to disfigure the foliage. Use no more fire heat than may be indispensable, and be careful to counteract its drying effects on the atmosphere, either by means of evaporating-pans or by sprinkling the border, &c., as may be necessary, to prevent anything like a dry, parching state of the atmosphere. Look well to plants in a growing state, such as Leschenaultias, and Pimeleas; remove the bloom as fast as it appears, but those plants of the former which are intended for early blooming must not have their flowers removed after this time. The number of plants brought forward will depend upon the demand, and must be regulated accordingly. Azaleas and Rhododendrons for forcing, still out of doors, must have some protection should severe weather occur, or remove them to any spare house till wanted. Narcissus, Hyacinths, &c., should be protected by a frame; as they now begin to grow, remove the plunging material down to the surface of the pots to prevent them rooting upwards. Mignonette and Neapolitan Violets will require abundance of light and air to keep them from damping. As a change from the present to severe weather may come on suddenly, be provided with ample means for covering pits and frames should it occur. As, with the exception of forced plants, most of the others are now in an inactive state, the temperature of plant-houses should fall to its minimum point, consistent with the safety of the various inmates. Nothing can well be worse for the development of a healthy, vigorous growth in plants than subjecting them to a high temperature at the present season of the year when light, so important to the healthy action of vegetable life, cannot accompany it.

STOVE.

Here all is still and quiet. Keep a moderate heat of from 50° to 60°, and give plenty of air. The Ixoras should be elevated near the glass to set their bloom, and have plenty of air at all times; keep them comparatively dry. Stephanotis, Allamandas, &c., may be potted and trained preparatory to starting, and the staking of all specimen plants must be proceeded with as fast as possible.

PITS AND FRAMES.

Plants of a succulent character will require much attention during damp, rainy weather. Geraniums, Calceolarias, &c., are very liable to become mouldy. Remove all leaves so affected as soon as they are discovered, or the evil will spread. —W. KEANE.

DOINGS OF THE LAST WEEK.

THE general work has been very much the same as in previous weeks. Some time was taken up in preparing, by ornamenting for Christmas festivities, which we hope will never become so old-fashioned as to lose their force and influence upon all ranks and ages of the community. Keenly enjoyed as Christmas gatherings are by the young, we question very much if they are not even more beneficial to those getting up in years, as in their case especially it is well that the heart should be kept young even whilst the body is feeling the effects of age.

In ornamenting a room with evergreens, there is generally a great objection to anything in the shape of a nail in the wall; but much may be done by having poles covered, a flat piece of board fastened to the top, and that covered with layers of cloth to go against the wall, and then these poles may be connected together with strings of leaves; and the running line obtained, all sorts of festoons and wreaths may be added at pleasure. For this purpose the twigs of Laurel, Laurustinus, Holly, &c., should not be too large, so that they may be nicely tied to the cord; and the more neatly this is done, the more nice and symmetrical will the wreaths and festoons appear. A good variety may be given even by making the most of the strings of common Laurel, and having prominent parts done with Laurustinus in bloom, and different colours of Holly, with or without flowers, natural or artificial.

Christmas Trees.—These are events chiefly for the young, and beautiful they look when well done. We mention them here because we find there is a great difficulty with some of our friends—first, in obtaining a symmetrical tree, and, secondly, in making it stand upright when it is of a large size, and more especially if much weight is hung upon it. This must be the only excuse for adverting to such a simple matter here; but the simplest matters are often the most puzzling to those who have never attended to them before. Last year we heard of more than one Christmas tree that came to grief, falling over on its broadside just when the children were clapping their hands in approbation at the brilliant light from the many coloured wax candles, and the glitter of many a beautiful toy.

Of all trees the Spruce is the best for a Christmas tree, as the dark foliage contrasts well with the brilliancy when the candles are lighted. The tree may be of any size; from 10 to 13 or more feet would be a good height from the floor for a large party and a large room. We do not trouble ourselves with the roots of the tree, but cut it over at the desired height. The more regular the layers of branches are the better, and if the foliage on them should be rather thick, a good deal may be cut away from the lower side of the branches, so that the light may appear to more advantage and the different things suspended be better seen. This will also secure the candles fixed on the different tiers burning without coming in contact with any of the twigs above them. The long point of a young Spruce tree also forms a natural place, as it were, for fastening the principal flag to, and less flags may be fastened to stand out obliquely from the base of this terminal shoot. The tree will always look best when, from the wide branches at the base to the terminal shoot, a somewhat equal but slightly irregular cone is formed of the different layers of branches. Were you to search a whole day in a wood for a fine-balanced tree, you would not find one in which there would not be some breaks in the conical outline, and hence, where a very fine regular effect is required, not only will the branches require thinning in some places, but it would be well to have a number of branches in reserve from the largest to the smallest size. By means of a large gimlet for the smaller branches, and an auger for the larger ones, we can make each layer or ring of branches regular all round—that is, moderately so, so as not to interfere with the natural appearance of the tree, by securely fastening a branch in the bole where wanted, and of the requisite length. By this means the poorest and most unsymmetrical tree may be rendered very symmetrical. This is all that would be required where the articles to be suspended were light; but when they are heavy and useful, as for a women's club, all the main branches could be kept firmly in their places, and hold a good weight without being depressed out of shape, by a fine copper wire being fastened 2 feet or 30 inches from the top of the tree, taken round each main branch from top to bottom, and then fastened by a nail to the tub, in which the tree was placed. From six to a dozen of such strings would keep all the main branches in their places, and as the higher tier could not be unduly depressed too close to the branches beneath, the candles might burn with little or no attendance. We recommend small brass wire instead of small string, because hardly to be seen, and also because string would be liable to be burned, and then the weight might unduly depress the branch. For light toys no such bracing would be required.

Some of this work may be done before the tree is fixed, but the most particular should be done afterwards. As a pot for the tree, nothing answers better than a moderate-sized tub or an old beer-barrel without one end. A four-gallon barrel will do for a small cut-over tree; a nine-gallon barrel will hold a large one, on which almost any likely weight may be suspended. In placing, the first proceeding is to saw the bottom of the bole of the tree across horizontally. Then we measure the bottom of the vessel, say a barrel, and if it is circular we take a board cut round, and half an inch less in diameter than the inside diameter of the vessel. This is nailed at the centre securely to the centre of the bole of the tree. The tree is then lifted, and the board and the base of the tree are placed in the barrel, the board resting on the bottom of the barrel. This is a better holding than even a lot of roots would be. On the top of this board the barrel or tub is filled to the top with bricks or stones and sand well jammed in, and no common weight will cause tree or tub to swerve. The top and sides of the vessel may be concealed with Ivy, &c. A Spruce tree has a good weight of itself; and when much weight has to be put on it, some such precautions are necessary if the tree is to maintain a natural position, and the floor of the room is to be encumbered by no bracings. No doubt there are other modes of making and then securing fine symmetrical Christmas trees; and as we learn that in some parts of the country these trees will be in request until at least the 12th of January, if any extra hints can be given before that time we are sure that many would be obliged. We have merely treated of the tree in its skeleton appearance, or in its merely gardening point of view. The furnishing of the tree is a matter for the ladies, who can do it with a grace that few of us can hope to equal, though we can appreciate it when done.

KITCHEN GARDEN.

Mushrooms.—In our out-door open shed the Mushrooms were like broad blue Scotch bonnets; and we mention the fact for the purpose of disclosing a great secret. As the bed had become a little dry from the covering, they were watered all over the bed from the spout of a pot, with water in which dried cowdung had been soaked. Now, for such watering of Mushroom-beds we rather disapprove of manure water from any dung that is in a green state; but when previously dried and then soaked, we have great faith, so far as large Mushrooms for broiling are concerned, and we would prefer dried sheep and dried deer-dung to cowdung. In all such watering we never like young Mushrooms to be touched with the water, it is apt to make them feathery, and therefore we prefer the spout of the pot to the rose; and if the bed should be at all dry whilst the surface is moist enough, we prefer making holes with a stick instead of soaking the surface soil.

FRUIT AND ORNAMENTAL DEPARTMENT.

Much the same as last week. Managed to plant out in well-prepared rich borders, lots of the single and double blue Violets, which had been pricked out thickly in a temporary bed. A pressure of other work prevented us striking cuttings, or dividing the plants of Neapolitan Violets, growing, and then lifting them into a frame or pit in autumn, which along with never allowing a runner to appear, is the best plan for managing such desirable plants. Some plants in a pit were put in late last season, and being rather small, we thought they might do with top-dressing for another year; but although they will do fairly they will not be so good as if they had been treated as stated above.—R. F.

TRADE CATALOGUE RECEIVED.

James Veitch & Sons, Royal Exotic Nursery, King's Road, Chelsea, S.W.—*Catalogue of Garden and Flower Seeds, &c.*—*List of Gladiolus.*

COVENT GARDEN MARKET.—December 29.

A return to dulness in the trade generally is the characteristic now, and heavy consignments reach us both English and foreign, there being a large supply of rough home-grown Apples, which hardly command prices to pay commission. Pears are limited to Winter Nelis, Glou Morceau, and Passe Colmar. Some excellent Pines have come from the Azores, quite equalling those we have had occasion to remark upon in former years. The best Potatoes have slightly advanced in price.

TO CORRESPONDENTS.

*** We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed *solely* to *The Editors of the Journal of Horticulture, &c.*, 171, *Fleet Street, London, E.C.*

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

Hyacinths in a Room (*C. M. W.*).—The beginning of October is the best time to pot Hyacinths and to place them in glasses. You may pot the small bulbs now in 4½-inch pots, and large ones in six-inch pots. Drain the pots well, and use a compost of turfy loam two-thirds, and well-rotted manure one-third, with a free admixture of sharp sand. Three parts fill the pots with soil, place on the surface a little sand, and on this set the bulb in the centre of the pot; then fill in soil around the bulb, so as to be level with the crown, leaving the least possible part of the crown uncovered. Give a gentle watering, and place the pots in a dark cupboard for a fortnight, then set them on a ledge or shelf in a window having a southern aspect; keep the soil moist by watering, never allowing it to become either too wet or too dry, and turn the pots round frequently so as to have the spike and foliage erect. If you grow Hyacinths in glasses, fill these to within an inch of the bulb with soft water, and place them in a dark cupboard until the bulbs begin to push and have made considerable progress. A piece of charcoal about the size of a small walnut may be put into the water, and it will tend to keep the water sweet. Do not change the latter so long as it remains sweet, and when it is changed use soft water which has been in the house some hours. Keep the glass replenished with water as this evaporates.

Azaleas Forcing (*A Youngster*).—Your house with a day temperature of 60°, and a night one of 50°, is suitable for bringing on Azaleas. In such a temperature, with a fair amount of ventilation and a moist atmosphere they will flower in six or eight weeks, dependant, of course, on the state of the buds. Some Azaleas lose many of their leaves at this season; many shed them through their having had the soil much too dry at some time.

Azalea Culture (*H. H.*).—The small-leaved kinds you name do not require treatment different from that of Azaleas generally. It is seldom we find it necessary to thin out the shoots of Azaleas, for weakness is favourable to flowering rather than otherwise, and gross shoots frequently do not flower. We fear you do not give the plants liberal treatment, nor sufficient moisture, as they are so liable to thrips.

Primula sinensis Flowers (*D., Newark*).—The pips are very fine, but no judgment could be formed of their merits, for they were bruised by the post-office stamping. Flowers must be sent in a box and in damp moss.

Covering Peach Trees (*Agnes*).—It is not necessary at this season to protect Peach trees. When the buds exhibit indications of swelling the covering may be put on, and remain on day and night in order to retard the blossoms. After the flowers open the covering should only be used at night, except on frosty or foggy days. Whenever the days are mild the covering should be removed during the day. Your proposed mode of protection is very good, only the covering must not remain down by day after the blossoms expand, when the weather is fine and mild. The mesh of the nets should not exceed a quarter of an inch. Woollen nets are best, but cotton will do if the meshes are not too large. You may double or treble the netting.

Cucumber Fruit not Setting (*James Pim*).—The fruit fall when they should swell because you do not fertilise the flowers, which is necessary with some kinds at this season. Other causes are a deficiency of bottom heat or a too high night temperature. With no particulars we are unable to advise further.

Vacant Ground (*T. M.*).—Fork over your light sandy soil now, and pick out the roots of weeds, but do not lay on manure. Your ton of scrapings from the footpaths, mixed with leaves, weeds, &c., and to which you have added three pecks of lime, will be further improved by the same quantity of salt the next time you turn it over. Put this compost on the ground in the spring when digging, previously to planting, sowing, &c. The "Garden Manual" will suit you. If you enclose twenty postage stamps with your direction you can have it free by post from our office.

Cotton Seed of all varieties may be obtained from the Secretary of the Cotton Supply Association, Newall's Buildings, Manchester.

In-door Plant Case (*Lover of the Country*).—Either of those you mention would do for forcing on a small scale.

Everlasting Flowers (*E. M. B.*).—The varieties of each species of what are termed "Everlastings," are so numerous that it is impossible to identify them—in fact, they are unnamed. The two heads you enclosed, for instance, are each Helichrysum bracteatum, and in ordering seeds of them, all that you could say to distinguish them would be to describe one as the white, and the other the crimson variety. The large yellow Everlasting is the yellow variety of H. bracteatum. The small yellow, if you mean that used in constructing "Immortelles," is Gnaphalium arenarium.

Protecting Pear Blossom (*A. Q.*).—In most cases it will be sufficient if a piece of thin calico or tiffany be thrown over each bush or pyramid, there being at each corner a piece of string which can be tied to the tree so as to prevent the covering being blown off by the wind. Where convenient a stout stake may be inserted by the trunk, and extending 1 foot higher than it, and then other stakes should be placed against this upright, outside the branches, one end resting on the ground and the other secured with string to the upright. These stakes, which may be slaters' laths, 1½ by ½ inch, should be placed 2 feet apart in a circle round the tree. The covering being fastened with string at a distance of 1 foot from the ground, will be secure against wind, and borne at such a distance from the blossom as not to injure it.

Primula Seed Sowing (*Anxious to Know*).—To have good Primulas, seed from good flowers must be sown, and to secure this the purchaser must give rather a high price. Good Primula seed is dear. Your time of sowing is suitable for an autumn and winter bloom. Our plan is this: the seed is sown in the first week in March in pans one-third filled with broken pots, an inch of moss, cocoa-nut fibre, or the siftings of the compost being placed thereon; and then the pans are filled to the rim with turfy loam, sandy peat, leaf mould, and silver sand in equal parts, passed through a half-inch seive. The surface is made smooth, the seeds scattered thinly over it, and just covered with the same compost. A gentle watering is then given, and the pan is placed in gentle heat, such as that of a Cucumber-frame. Care is taken to keep the soil moist, but by no means wet, and when the plants appear the pan is brought near the glass, so that they may have abundance of air and all the light possible. Here they remain until they are of sufficient size to pot off; they are gradually hardened off and removed to a vinery or other house, and in June or early in July transferred to a cold frame, where they are shifted as occasion may require.

Swollen Black Currant Tree Buds (*W. J.*).—We know of no insect that deposits its eggs in the buds of the Black Currant "causing them to swell to an enormous size." If you send us shoots having on them some swollen buds we will endeavour to determine the name of the insect.

Number of Men Needful (*R. F.*)—A general rule used to be a man for each acre; but flower gardens and pleasure grounds need much more labour than kitchen gardens. Soil, proportion of each department, and other considerations, have an influence also.

Vinery (*A Scot*.—We do not think you would do any good with a vinery on such a north-east aspect without heating the house, and even then the situation would be unsuitable. We would prefer devoting the wall to Plums, Cherries, and Pears.

Vine Roots in Wet Subsoil (*B. T.*).—The best thing you can do, having drained the border, is to concrete the bottom, place 6 or 10 inches of rubble over it, and having carefully taken up the roots of the Vines, to wrap the roots in mats covered with straw, make a fresh border, and replant carefully about 6 inches from the surface. Add as much hot litter on the surface as will give a temperature of from 65° to 80° in the earth, and let the Vines break naturally.

Tubular Boiler (*Tubular*) —We do not remember the account of the boiler your refer to in 1862. We do our utmost to oblige our readers, but we cannot afford time to seek for references for them; they must do that. We place less value than some people on having pipes with water under the fire; we believe that good bars are in every way better. Your boiler ought to heat 1,200 feet; but a No. 4 does not give us a definite idea, as different makers differ in size, and the size would have enabled us to have judged better. If well set, &c., do you keep the heat from going up the chimney by a damper?

Names of Fruits (*Richard Nicholson*).—*Apples:* 1, Warwickshire Pippin; 2, Crimson Queening; 4, Fearn's Pippin; 5, Alfriston; 6, Hollandbury. *Pear:* 1, Susette de Bavay.

Names of Plants (*A Novice*).—1, Adiantum, insufficient to determine the species; 2, Onychium japonicum; 3, Pteris longifolia; 4, Gymnogramma calomelanos; 5, Aspidium molle (?) (*Fred*).—Oporanthus luteus. (*Amateur*).—We cannot satisfactorily name the scraps you send. 1 is

Specularia speculum; 2, probably a leaf of Albizzia lophantha; 3, Centaurea ragusina; and 4 may be Cineraria maritima. (*J. Bryan*).—1, Rivina levis; 2, Euphorbia jacquiniæflora; 3, Justicia speciosa; 4, Habrothamnus fasciculatus. (*An Old Subscriber*).—Garrya elliptica. (*Frederick Webber*).—1, Pellæa geraniifolia; 2, Pteris semipinnata; 3, Phlebodium aureum; 4, Platycerium alcicorne (?); 5, Davallia canariensis.

METEOROLOGICAL OBSERVATIONS in the Suburbs of London for the Eight Days ending December 29th.

Date.	Barometer.		Thermometer. Air.		Thermometer. Earth.		Wind.	Rain in inches.	General Remarks.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

THE PAST AND THE FUTURE.

In this first Number of "our Journal" appearing in 1867, we, as is our custom, now review the past and salute the new year. We hope we are, as we should be, very grateful; we have been spared to address our numerous friends again. It is now many years since we first did so, and although the "insatiate archer" makes his annual gaps, yet we are thankful that the original phalanx remains a numerous and serried one.

Many will remember the past year with gloomy feelings. It has been to them, we fear we may say to most, a period of gloom, loss, and trial. We are indeed thankful we have not to do with those themes, nor should we advert to them were it not that the destruction of cattle owing to the rinderpest, and the consequent rise in the price of meat, have forced the public of all classes of society to look at poultry as a valuable auxiliary in providing food for a nation. The wonderful increase in our importations of eggs and every article of food produced in the farmyard has awakened the attention, not only of those who seem to consider it their province to provide the food of millions, but of the political economists who assess the loss that is suffered by the community when money leaves the country. We have no doubt the exceptional state of the food market during the past year has awakened the attention of those men whose energies are never directed to a subject without producing a visible result. There can be no doubt that the question is capable of great development, and that food, both meat and eggs, may be provided in much larger quantities than at present, without any increase of expense.

The beginning of 1866 was notorious for the number of companies that were formed, and of speculations that were entered into. Poultry was represented by two companies; one has been some time defunct; the other is, we believe, the "sick man" of the poultry world—no other result could be expected. None but a very theorist could have dreamed that poultry could be profitably bred on five acres of land in sufficient quantities to enable the Company (limited) to sell it by weight at per pound in the metropolis.

While on the subject of production, we must mention the fact of several hatching machines being brought before the public. We anticipate much good from them. They will never supersede hens, nor would it be a gain if they did, but they will undoubtedly increase the poultry stock.

The Poultry Club still exists; some of its originators and old office-holders are retiring, and a few new members are joining. The account furnished of their Rochdale Show was discouraging, and the "Standard of Excellence" has not become the text book of amateurs. We wish them every success in all that tends to the good of the pursuit.

Birmingham, the great mother of shows, and the originator of most of our schemes as connected with exhibitions, has again been in the van of innovation, and new ideas were adopted with success at her last Show. It is no uncommon thing in larger undertakings than poultry shows for classes to clash, and for one to ignore the other. Directors and managers can speak feelingly of conflicting interests, and exhibitors, spectators, and purchasers form three of them. The first class is often threatening to withdraw from exhibiting unless certain things which they desire are complied with. The third is supplied from the second, and they declare justly that they supply the sinews of war. Birmingham has tried to please all, and has partially succeeded. Purchasers wished to be able to buy a hen of their own selection, and one that might be bred from without having brother and sister in the yard. The new classes have proved a success, having nearly doubled the sales; while purchasers have been suited, the sales of the birds have proved a welcome addition to the profits of the prizetakers. Manchester has again been the scene of a large and successful Show. Mr. Jennison deserves well at the hand of amateurs for the care and punctuality that attend all his dealings.

The South is giving signs of vitality, and shows are springing up. The Royal Agricultural Society of England will again have poultry at Bury St. Edmunds, where the show will be held this year.

Dorkings have held their own, but have made no progress in weight. There must be a limit, and they have, perhaps, attained it. Spanish remain stationary. Cochins are decidedly improving in quality and popularity. Brahma Pootras are realising our predictions, and not only form a very large class, but an offshoot, the Light Brahmas, is treading on the heels of the Dark birds. Polands increase in numbers and quality. Game are always admirable, but they have surpassed themselves in the past year. Hamburghs are numerous and good, but we doubt whether the best pens are as meritorious as they were some years ago. Game Bantams are deservedly favourites with the public, and their classes are not only numerous but produce exquisite specimens; Blacks and Whites hold their own, but Sebrights fall off in numbers. The Rouen Ducks have at last beaten the Aylesburys in weight, and have also formed more numerous classes. Geese are still improving. We should be afraid after what we have seen to fix a limit to the weight they may be made to attain. The same may be said of Turkeys.

We feel somewhat as we should imagine a Judge feels when at a maiden assize he is presented with a pair of white kid gloves. We have no fault to find, no grievance to dilate upon, no complaint to make. While this gives us great pleasure in our task, of necessity it curtails our paper. Our profession of faith is an old one. We have to tell the truth so far as lies in our power. The old saying will recur to many, "*On ne se fâche que de la vérité.*" If we have caused pain by any remark, the fact that we did not intend to do so will make the *amende* easy—we apologise for it. Our career has been smooth and easy through a troublous time, we thank our subscribers for it.

Our support years ago, and our great comfort and happiness now, have been, that among those who form our subscribers we have none but friends. Our success has proved that we were not mistaken in the line we chalked out when we started; and now, when we address all, our subscribers, contributors, and friends—when we close a year of unusual trial to those who are still numbered among the working classes—we feel strong in our motives and practice, and hope and believe there will be a hearty response from all when, forgetting the past, except so far as it may have taught useful lessons, we heartily wish to all

A Happy New Year.

Walsall Poultry Show.—As an additional attraction to this Show, sweepstakes are being arranged for the following

varieties of poultry:—Dorking, Spanish, Buff and White Cochins, and the two classes of adult Game. Subscription one guinea each, to be divided among subscribers only into two prizes—three-fifths for the first, two-fifths for the second. The Hon. Secretary, Mr. J. Bayliss, will receive subscriptions, which will close on the same date as the entries—viz., January 5th. Several gentlemen have already given in their names as subscribers to the Buff Cochin and Game classes.

THE POULTRY CLUB.

Absence from home prevented me last week from correcting one or two errors in your report of the Club meeting at Birmingham. The first I observe is with reference to the motion proposed by me with regard to the detention of the Club funds by the Hon. Treasurer without explanation. You say, "An explanation was offered by Mr. Zurhorst exculpating Mr. Tudman," when in point of fact the very reverse was the case. The facts are as follows: Mr. Tudman, having had due notice of the resolution calling on him to explain why he had not paid over the money voted and ordered by the Stewards on account of the Rochdale prize list, came to the meeting, anticipated the call for an explanation by giving in his balance-sheet, resigning, and leaving the room before the motion could be brought on, without remark of any kind, except that some of the money received on account of the "Standard of Excellence" had not passed through his hands. Mr. Tegetmeier explained that he had offered it to Mr. Tudman, who declined to receive it, and that as a last resource he had remitted it to the Hon. Secretary.

As Mr. Tudman had apparently run away to avoid explanation, I deemed it necessary to offer some remarks, before withdrawing the motion, as to why I brought it forward. In doing so I dealt as lightly as possible with the absent; but I was compelled to show how far, in the gratification of private feeling, Mr. Tudman had jeopardised the credit of the Club, and I stated circumstantially my reasons for calling on Mr. Tudman for a public explanation. As he did not choose, though filling a most responsible office, to afford this, I was compelled to come to the conclusion that his conduct was unjustifiable to the honourable body for which he was trustee; and so far from exculpating him I left the facts in the hands of the meeting, expressing my own opinion of the undignified and selfish course he had pursued.

The motions respecting the judges were consolidated; and so close was the division of opinion, that the first voting resulted in a tie. The second voting had the same result, an additional vote having been obtained on each side, and the Chairman finally gave the casting vote.

There was no question submitted as to the disposing of the remaining copies of the "Standard," for the Club has no doubt on this subject, as there is still a fair demand, though not as great as at first.—F. W. Zurhorst, *Hon. Sec. Poultry Club, Donnybrook.*

Absence has prevented me replying to "A Member," whose letter appears in your Journal of the 18th ult.; but I am, no doubt, all in good time, and I am sure the spirit of fair play which always animates your Journal will afford me space. The communication in question is a tissue of misstatements from beginning to end. But to begin. He says, 'a member high in office informed him that the 'Standard' had been cast aside as useless long since," &c. Now this is so utterly at variance with the facts, that I am inclined to think "A Member" must have dreamed it (I should not venture to think it was a concoction), as the following figures are well known to all members, including those "high in office," who have taken the trouble to read the reports or attend the meetings. The "Standard" cost some £27 to publish and bind a five-hundred edition. The whole of the members then on the books received a free copy. The numbers sold have been sufficient to pay the whole expenses and leave a balance of from £8 to £10 applicable to other purposes, together with some 150 copies available for sale or presentation free to new members on application to the Honorary Secretary. At our next balance our publishers will have a goodly balance of cash to hand us, and I am this day sending off copies to individuals outside the Club who have applied for them. So much for assertion No. I. Now the next.

The numerous commendations of the "Standard of Excellence" that have appeared in the columns of the press, and its large sale, render any further comments on its merits unnecessary.

With reference to the Club Judges not judging book in hand, "A Member" again displays his ignorance of facts. I will simply quote a portion of the minutes of a meeting held the 1st of October, 1864, Mr. Kelleway in the chair. Mr. Beldon said that some misapprehension existed as to the rules for judging, "no judge could be expected to go about book in hand;" and it was then unanimously resolved that to prevent misapprehension the title of the forthcoming book should be changed from "Rules for Judging" to "The Standard of Excellence." The Club prospectus published in January, 1865, stated that it "was for the guidance of exhibitors," and to "obtain as far as possible uniformity of judging." I presume our well-informed "Member" (?) will now understand why the Judges at Rochdale did not go about book in hand.

As to the discussion and division on the additions to the Judges, I suppose "A Member" will allow others to entertain an opinion. It is a pity he did not, as he says he attended the meeting, assert his, instead of confining himself to writing anonymous uncertainties!

Again, with regard to the Rochdale Show, how reliable is "A Member's" information! how exquisitely just his information! He says the Rochdale Show must have cost the Club £30, and then says he was at the Birmingham meeting. Had he either opened his ears or lifted one of the balance sheets on the table, he would have seen that the Show unfortunately cost the Club £128 (not £30 as he suggests)—viz., £75 guarantee money, and £53 from Club funds, and that though the entries paid the prize list, the receipts at the door amounted in three days to but £43, the rain having come down incessantly from end to end of the Show.

I may add that copies of the balance sheet were laid upon the Club table, as well as sent to each guarantor, and the promptitude with which those gentleman to a man paid the call after receiving the balance sheet needs no comment. What Mr. Tudman said at the meeting I have stated above. I am in possession of the shorthand-writer's notes, and the omission of the full report respecting Mr. Tudman's resignation and its causes was dictated by a desire to avoid personality.

As to what Mr. Tudman and Mr. Ashton did for the Club, the minute-book before me shows that they attended the first meeting, with many other gentlemen at Liverpool, but that they proposed no resolutions. They were appointed joint Secretaries—Mr. Ashton speedily resigned, and Mr. Tudman followed him twelve months after.

With regard to the Club costing half its subscriptions to work, I have only to point to the fact that the annual income is £57, a small amount of which is in arrear, that no less a sum than £40 has been paid this year out of the Club funds towards the Show, and that Mr. Tudman by his balance sheet had upwards of £12 in hand at the Birmingham meeting, the printing, stationery, and postage for the whole year being under £8.

In conclusion I would advise "A Member" ere he again rushes into print to get up his facts a little more accurately. It was only due to the members of the Club that this refutation should be written, but no further anonymous correspondents will be recognised or replied to by—F. W. Zurhorst, *Hon. Sec., Poultry Club, Donnybrook.*

POULTRY JUDGING.

I see quite enough to dishearten exhibitors in the present system of judging, and the rejection of the motions on this subject before the Poultry Club show that we have little hope of reform in that quarter. The Poultry Club has proved a disappointment. I agree for the most part with the letter of your correspondent lately on the subject. I make no charges of dishonesty against the judges, although I am quite aware that dishonest judges do exist. I think a vast deal of mischief arises rather from a friendly feeling towards local exhibitors, and a pertinacious interference of officials, than from any premeditated favouritism.

Not a sufficient number of judges is employed, too much is expected of them, and many of them are willing to believe that they are competent to judge in all classes. Everything connected with the fancy breeding of poultry is undefined, uncertain, and unsatisfactory. There is no point of authority. We have no fixed rules—no standard by which to work; everything seems to be a matter of taste and opinion.

With this feeling I attached myself to the Poultry Club; but however good a man the present Secretary may be, the

members do not seem inclined to do anything. Except the "Standard of Excellence," which with all its faults is a useful production, nothing has been done.

I am inclined now to go in for poultry as an article for food. I dare say you have seen Mr. Geyelin's circular, "Our System of Selling Poultry, and the Remedy." He has, I think, the right plan, but at present he fails in bringing it to bear.

The National Poultry Company may answer as a place for breeding and selling good birds, but there is a want of vigour there, and under the present system they will not produce any change.

You will think I am a general grumbler, but I am sure you will agree with me in many things. I want to work certain reforms, and I will do so, if possible, without angry feeling or personal attacks.—Egomet.

SUNDRIES.

In reply to "Clericus," before he accuses his "Black Country" dealer of imposition in the matter of his Partridge Cochin cock, he should be able to *prove* that some imposition had been practised. I do not think any person conversant with the changes of plumage that fowls undergo in moulting, would be satisfied with the simple statement offered by "Clericus." Changes from black to white are well authenticated, and would appear much more like "shameful dishonesty," than the case mentioned, and yet Dame Nature may be alone to blame.

In reference to "Poultry Show Neglects," and "Exhibitor," I can sympathise with him in the matter of catalogues and prize lists, though not as relating to Newport. I have before now in the pages of "our Journal," advocated certain courtesies to exhibitors. A ticket of admission is one courtesy I have advocated; it might induce the exhibitor to attend the show, he might purchase, and thus aid the funds; and in any case I do know this, that it gives the exhibitor a more lively interest in the welfare of the exhibition. As to catalogues, I feel that exhibitors ought to be the *first* persons considered. I have gone myself to an exhibition to find all the catalogues sold, though I had ordered one. It does appear to me that exhibitors are really the backbone of exhibitions. This may be diseased imagination on my part, but I think that as the great majority must be unsuccessful, it would be worth the while of managers to pat all on the backs, and show them some little attention. Let it be a rule at every exhibition, to dispatch by the first possible post a catalogue and prize list to every exhibitor. Would the managers of a large show lose £5 by such generosity? I should say, certainly not; but a very few exhibitors declining to enter at a second show would cause a loss of far more than £5 in entries.

Railway charges, however, seem likely still to be the stumbling block to increase of exhibitors. To myself quite recently, obtaining prizes has not been sufficient to preserve me from losing money by exhibiting. I have just paid 4*s*. 6*d*. for one hamper of Polish fowls (therefore not heavy), travelling one hundred miles on a single railway, and since that I have sent to the Newport Show three pens for 5*s*. 2*d*.; the return journey cost me 10*s*. 3*d*., the distance being under one hundred miles. Mr. Cork is right, most probably, in his reply to "Exhibitor." The railway should be blamed for detention. I can only say my birds returned from New Shoreham in capital condition. One cock has been exhibited three times successfully since that Show, without being any the worse. This could not be if he had suffered from neglect at Shoreham. The "Exhibitor" at New Shoreham might probably, with trouble, have traced the packages, and found out where the fault was. Perhaps he had better pocket the affront. My crusade against the railways has ended, as I think, in all poultry parcels being charged to me on our local railway 50 per cent. extra. I cannot help fancying that orders have been given to all clerks to look out for my name, and to lay it on heavily.—Y. B. A. Z.

INCUBATORS.

If "Edgworth" and "A Spanish Breder" will put themselves in communication with me, I shall be most happy to reply to their queries about my incubator.

I have endeavoured to construct it to be as perfect as possible in command over internal and external temperature—I believe hitherto the weak point—and I will guarantee that if one is fitted according to my instructions, it shall keep the requisite temperature, 102° to 103°, absolutely without variation; further, that if the slight extra expense is incurred of having my outer anti-radiation casings, many a mishap of the gas or lamp going out will have no evil effect, for the incubator shall keep its proper temperature for six hours without any heating medium whatever. One thing, however, I cannot guarantee when an incubator has gone out of my hands—that is, another's attention thereto.

Lastly, in reply to "H. Wilcocks." There must be some error, for Mr. Massey assures me all correspondence is duly answered. May I request "H. W." to write once more?—Fredk. Schröder, *Manager, National Poultry Company (Limited)*.

MANCHESTER POULTRY AND PIGEON SHOW.

Most amateurs of experience anticipated a first-rate Show this year at the Belle Vue Gardens, Manchester, and their anticipation was correct, for the Show of December 21st, 22nd, and 24th, has been by far the best of any yet held under the management of the Messrs. Jennison. This is not to be wondered at, for every successive year proves only the more certainly that no better place exists for the accommodation of a large show, nor can there be any more praiseworthy individuals as regards the general attention paid to every portion of the valuable live stock exhibited. In proof of what we have just stated, a large quantity of home-baked bread was expressly made on the premises, each loaf being from 5 to 6 inches thick, and about the size of the large flagstones used for paving our general thoroughfares. These immense loaves of bread, each pretty well as much as a man could lift, had been made a few days previously, and were consequently in excellent condition for the purposes intended, being not in the least clammy, but, on the contrary, sweet and good-flavoured. They were broken to small pieces, well soaked in cold water, and then mixed with barley flour, and this constituted the first food of the poultry after being taken from their travelling baskets. During the whole Show, once each day they were allowed a similar meal, the remainder of their food being a mixture of excellent barley and Indian corn. From this careful management doubts cannot exist but that many pens of poultry will actually be returned in far superior condition to that in which they were received at Manchester. Nor was the scrupulous care of the proprietors of the Belle Vue Zoological Gardens expended exclusively on the poultry, as a very large entry of dogs had also been consigned to them. To meet the requirements of this host of animals, quite a string of living horses arrived at the Gardens a few days previous to the meeting, nor was a single one of these animals slaughtered until it had undergone veterinary inspection to ascertain if it was perfectly free from constitutional disease. The quantity of this flesh when mixed with a due proportion of barleymeal would have staggered the belief of almost any one. The small toy and pet dogs were provided also with other kinds of food more especially adapted to their respective wants. This careful management, under so experienced a supervision, renders the Manchester Show so popular and well supported. It is by experience proved that railway companies are always among the last parties to avail themselves of suggestions, however urgently directed; but we cannot forbear once again drawing the attention of railway directors to the impolicy of putting dogs and poultry to travel in the same van, for we are informed several valuable pens of fowls were destroyed by their canine fellow-passengers during transit, to the no small annoyance of the owners of the poultry, and as inevitably to the ultimate serious loss of the railway companies themselves, who, as a matter of course, are legally liable for such gross neglect and mismanagement.

The arrangement of the pens throughout the whole Show was admirably adapted for the inspection of the public, and it would, indeed, be invidious to particularise the merits too closely of individual classes, when we are fortunately enabled to say that scarcely an indifferent class throughout the whole Show could be selected. The Grey *Dorkings* were most commendable, the young classes exhibited (of a cockerel and pair of pullets) proving exceedingly good and popular. A reference to the printed prize list will show our readers that in this, as in almost all other breeds throughout the Show, the premiums were very widely sown. Perhaps besides being one of the most extensive, the best class in the whole Show proved to be the young Black *Spanish*. Never had the Judges awarded prizes to better specimens, nor could their condition throughout the whole entry be surpassed. The *Crève Cœurs* mustered strongly, and were good; nor were the *Polands* less worthy of our highest praise. The *Game* classes were remarkably well filled, but the condition of many of the birds from the late wet weather was not equal to what it might otherwise have been. In *Cochins*, both the Buff and the Partridge-coloured ones, the Manchester Show held a very high position: they were evidently the picked birds of the kingdom, most of them having been specially reserved by their owners to test their quality at Belle Vue. The young Buff Cochins, although the first prize was £10, strange to say, undoubtedly proved by far the least deserving of any of the Cochin classes.

Geese, *Turkeys*, and *Ducks*, were shown in great abundance; and here, as usual, Mr. Charles Jennison exhibited a very well-filled class of a great variety of "fancy" water fowls, taken purposely from the pools of the Gardens. Another scarcely less interesting feature of the Show was a class composed of foreign *Doves*, some varieties being so

small as hardly to be larger than sparrows, though of the most exquisite colour and markings.

This class for Doves, and the collection of *Pigeons* with which they were closely connected, were literally thronged with visitors during the whole time the Show was on view. The weather being very favourable, everything went off most satisfactorily.

DORKING (Coloured, except Silver-Grey).—First, Mrs. F. S. Arkwright, Etwall Hall, Derby. Second, Viscountess Holmesdale, Linton Park, Staplehurst. Third, J. Anderson, Ruthven House, Meigle. Fourth, J. White, Warlaby, Northallerton. Highly Commended, E. Shaw, Plas Wilmot, Owestry; J. White. Commended, Hon. W. H. Fitzwilliam, Wentworth Woodhouse; Rev. J. F. Newton, Kirby-in-Cleveland; J. Robinson, Vale House, Garstang; W. H. Walker, Shenfield, Brentwood. *Hens.*—First and Second, Viscountess Holmesdale. Third, Mrs. F. S. Arkwright. Highly Commended, W. McConnell, Chelford, Manchester; Miss Davies, Wrexham Road, near Chester; Duke of Newcastle, Clumber Park, Notts; Mrs. A. Hurt, Alderwasley, Derby; H. Anderton, Leigh, Lancashire. Commended, T. Statter, Stand Hall, Whitfield, Manchester; Admiral W. Hornby, Knowsley Cottage, Prescot; Mrs. Dale, Falconer House, Scarborough. *Chickens.*—First, D. C. Campbell, M.D., Brentwood. Second, Viscountess Holmesdale. Third, T. Statter. Fourth, J. White. Highly Commended, Admiral W. Hornby; Viscountess Holmesdale; J. Anderson; D. C. Campbell, M.D.; Mrs. F. S. Arkwright. Commended, E. Longton, Woolton, Liverpool; Miss Davies. *Pullets.*—First, Duke of Newcastle. Second, Miss Davies. Third, D. C. Campbell, M.D. Highly Commended, Hon. W. H. Fitzwilliam; Miss Davies; Messrs. Gunson & Jefferson, Whitehaven; J. K. Fowler, Prehendal Farm, Aylesbury; Viscountess Holmesdale. Commended, Viscountess Holmesdale; J. Anderson.

DORKING (Rose-combed).—Prize, Viscountess Holmesdale. *Chickens.*—First and Second, Viscountess Holmesdale.

DORKING (White).—First, Second, and Third, H. Lingwood, Needham Market, Suffolk. Highly Commended, J. Robinson.

DORKING (Silver-Grey).—First, R. D. Holt, Orrest Head, Windermere. Second, Rev. T. O'Grady, Hognaston Vicarage, Ashbourne. *Hens or Pullets.*—First, Rev. T. O'Grady. Second, Miss Milne, Otterburn, Kelso. Highly Commended, D. Parsons, Cuerden, Preston; J. Hardie, Corbie Ewes, Langholm.

EXTRA DORKING PRIZES.—First, Admiral W. Hornby. Second, Messrs. Gunson & Jefferson. Third, J. Robinson. Commended, J. Anderson.

SPANISH.—*Cock.*—First, Messrs. Burch & Boulter, Sheffield. Second, H. Lane, Ashley Road, Bristol. Third, R. Teebay, Fulwood, Preston. Fourth, E. Jones, Berkley Place, Clifton. Highly Commended, T. B. Hartley, Heywood, Manchester; D. Parsley, Kingsdown, Bristol; R. Teebay; J. H. Wilson, St. Bees, Whitehaven. Commended, W. R. Bull, Newport Pagnell; J. Thresh, Bradford. *Hens.*—First, E. Jones. Second, H. Beldon. Third, E. Brown. Highly Commended, G. Bridle, Didsbury; Messrs. Burch & Boulter; J. Thresh; W. H. Walker. Commended, J. Stevens. *Chickens.*—First, D. Parsley. Second, Viscountess Holmesdale. Third, E. Jones. Fourth, T. Cliff, Hanley. Highly Commended, Miss Davies; Miss Biggar, Ecclefechan. Commended, E. Jones; A. O. Worthington, Newton Park, Burton-on-Trent; W. R. Bull; J. R. Rodbard; Hon. Miss D. Pennant, Penrhyn Castle, Bangor; Messrs. Burch & Boulter. *Pullets.*—First, J. Stephens, Walsall. Second, W. R. Bull. Highly Commended, T. B. Hartley.

EXTRA SPANISH PRIZES.—First, H. Beldon. Second, Third, and Highly Commended, R. Teebay. Commended, E. Brown, Sheffield.

COCHIN-CHINA (Cinnamon and Buff).—*Cock.*—First, E. Smith, Middleton, Manchester. Second, H. Tomlinson, Birmingham. Third, A. Fenton, Crimble Hall, Rochdale. Fourth, Rev. F. Taylor, Keastwick, Kirkby Lonsdale. Highly Commended, A. Fenton; R. White, Broomhall Park, Sheffield. Commended, G. Fell, Springfield, Warrington; R. White; H. Bates, Yardley, Birmingham; H. Mapplebeck, Woodfield, Moseley. *Hens.*—First, H. Tomlinson. Second, E. Smith, Middleton. Third, A. Fenton. Highly Commended, G. Fell; Rev. C. Spencer, College House, Attleborough; A. Fenton; Mrs. R. White. Commended, W. A. Taylor. *Chickens.*—First, H. Mapplebeck. Second, G. Fell. Third, Hon. Mrs. Sugden, Stapeley House, Nantwich, Cheshire. Fourth, A. Fenton. *Pullets.*—First, H. Mapplebeck. Second, T. Boucher. Highly Commended, Hon. Mrs. Sugden; Rev. C. Spencer; W. A. Taylor. Commended, Hon. Miss D. Pennant.

COCHIN-CHINA EXTRA PRIZES (Cinnamon and Buff).—First, A. Fenton. Second, J. Nelson, Heaton Mersey, Manchester. Third, C. Jennison, Belle Vue, Manchester. Highly Commended, A. Fenton.

COCHIN-CHINA (Brown and Partridge-feathered).—*Cock.*—First, R. White. Second, J. R. Rodbard, Aldwick Court, Wrington, Bristol. Third, A. Fenton. Highly Commended, E. Tudman, Whitchurch, Salop. Commended, Messrs. Bowman & Fearon, Whitehaven; E. Tudman; J. Elliott, Westleigh, Leigh; A. Fenton; J. R. Rodbard. *Hens.*—First, J. Stephens. Second, E. C. Stretch, Ormskirk. Highly Commended, E. Tudman; A. Fenton. Commended, E. Smith. *Chickens.*—First, E. Tudman. Second, J. Horrocks, Tonge, Middleton, Manchester. Third, E. C. Stretch. Commended, A. Fenton. *Pullets.*—First, J. Pool, Ulverston. Second, E. Smith, Highly Commended, E. Tudman; A. Fenton. Commended, E. C. Stretch; C. E. Ridsdale, Copley, Halifax.

COCHIN-CHINA (White).—*Cock.*—First, R. Chase, Balsall Heath, Birmingham. Second, F. W. Zurhorst, Donnybrook, Dublin. Commended, Rev. W. J. Mellor. *Hens.*—First, R. Chase. Second, F. W. Zurhorst.

EXTRA COCHIN-CHINA PRIZES.—First, R. Chase. Second, E. Tudman. Third, E. C. Stretch. Highly Commended, J. Holme. Commended, Hon. Mrs. Sugden; E. Tudman; H. Beldon; J. Horrocks.

BRAHMA POOTRA (Dark).—First, R. W. Boyle. Second, J. Stevens. Third, W. Hargreaves. Highly Commended, M. Brookshank. Commended, T. Pomfret; H. Lacy, Hebden Bridge; J. K. Fowler; G. H. Roberts.

BRAHMA POOTRA (Light).—First, A. O. Worthington. Second, C. Maples, jun.

BRAHMA POOTRA (Either variety).—*Cock.*—First, R. W. Boyle. Second, Col. Stuart Wortley. Third, J. Shorthose. Commended, C. Cork.

EXTRA BRAHMA POOTRA PRIZES (Any variety).—First and Second, T. Pomfret.

POLISH (Any variety).—First, Sir St. G. Gore, Bart. Second, P. Unsworth, Highly Commended, G. C. Adkins, The Lightwoods; Sir St. G. Gore, Bart.; T. Walmsley; H. Beldon; H. Carter; Mrs. C. W. Brierley. Commended, T. Walmsley. *Chickens.*—First, P. Unsworth. Second, Sir St. G. Gore, Bart. Highly Commended, G. C. Adkins; P. Unsworth. Commended, G. C. Adkins; R. Charlesworth, Manchester; Miss J. Baily, Hartley, Wintney, Hants.

CRÈVE CŒUR.—First and Second, W. Blinkhorn, Waterdale, near St. Helen's. Third and Highly Commended, Col. Stuart Wortley.

GAME (Black-breasted Reds).—First and Second, Sir St. G. Gore, Bart. Third, R. Scrimminger. *Cock.*—First, R. Pashley. Second, T. Gorton, jun., Cheetham Hill, Manchester. Third, R. Scrimminger. Highly Commended, Sir St. G. Gore, Bart; J. Halsall, Ince, near Wigan. Commended, F. J. Asthury, Charlotte Street, Manchester; Sir St. G. Gore, Bart.; C. P. Ackers, Bickersham, near Wigan; H. M. Julian. *Chickens.*—First and Fourth, Sir St. G. Gore, Bart. Second, S. Matthew. Third, W. Callender, Welshpool. Highly Commended, Sir St. G. Gore, Bart.; F. Sales. Commended, F. J. Astbury; J. Halsall.

EXTRA GAME PRIZES (Black-breasted Reds).—First, P. Norbury. Second, Mrs. Hay. Third, J. Anderson.

GAME (Brown and other Reds, except Black-breasted).—First, Sir St. G Gore, Bart. Second, T. Statter. Third, J. Wood. Highly Commended, Sir St. G. Gore, Bart; R. Pashley; S. Matthew. *Cock.*—First and Third, Sir St. G. Gore, Bart. Second, R. Scrimminger. Highly Commended, T. Statter; C. Chaloner; R. Swift. Commended, J. Fletcher; G. W. Cooper. *Chickens.*—First, Rev. F. Watson, Messing, Kelvedon, Essex. Second, J. Anderson. Third, E. Aykroyd, Girlington Road, Bradford. Fourth, J. Wood. Highly Commended, F. Sales; G. Clements; M. Billing, jun., Erdington. Commended, T. Statter; Sir St. G. Gore, Bart.

EXTRA GAME PRIZES (Brown and other Reds, except Black-breasted).—First, S. Matthew. Second, E. Aykroyd. Third, N. Grimshaw.

GAME (Black-breasted and other Reds).—*Hens.*—First, T. West. Second, W. Cox. Third, Sir St. G. Gore, Bart. Highly Commended, T. Robinson; G. Clements. Commended, W. Bourne; J. W. Harrison; C. Marlow. *Chickens.*—First, J. Wood. Second, J. Halsall. Third, W. W. Pyne. Highly Commended, H. J. Stokes. Commended, E. Aykroyd.

GAME (Duckwings, and other Greys and Blues).—First, Duke of Newcastle. Second, A. K. Briggs, Rawden, near Leeds. Third, S. Matthew, Stowmarket, Suffolk. *Chickens.*—First and Second, Sir St. G. Gore, Bart., Hopton Hall, Wirksworth, Derbyshire. Third, W. Horton, Albrighton, near Wolverhampton. Commended, J. Firth, Halifax.

GAME (except Black-breasted and other Reds).—*Cock.*—First, F. Sales, Crowle, Lincolnshire. Second, J. Charlton, Chapelthorpe, near Wakefield, Yorkshire. Third, Sir St. G. Gore, Bart. *Hen.*—First, J. Charlton. Second, Sir St. G. Gore, Bart. Commended, J. Firth; J. Halsall, Ince, near Wigan.

GAME (White and Piles).—First, Sir St. G. Gore, Bart. Second, T. West, St. Ann's, Eccleston, St. Helen's. Highly Commended, G. Wostenholme, Queen Street, Sheffield. Commended, Sir St. G. Gore, Bart. *Chickens.*—First, R. Scrimminger, Pailton, near Lutterworth, Warwickshire. Second, R. Pashley. Highly Commended, Sir St. G. Gore, Bart.

GAME EXTRA PRIZES (except Black-breasted and other Reds).—First, T. Burns, Ahram, near Wigan, Lancashire. Second, J. Anderson. Commended, P. Norbury, Bowden, Cheshire.

DUCKS (White Aylesbury).—First, Captain H. B. Lane, Bracknell, Berks. Second, J. K. Fowler. Third, E. Leech.

DUCKS (Rouen).—First, Sir St. G. Gore, Bart. Second, T. Burns. Third, T. Statter. Fourth, T. Wakefield, Golborne, near Newton-le-Willows. Highly Commended, E. Longton; T. Statter; Miss Davies; C. P. Ackers; E. Leech; J. Nelson; S. H. Stott; J. Holme, Knowsley, Prescot, Lancashire. Commended, A. Fenton.

DUCKS (Black East Indian).—First, A. Fenton. Second, C. Sidgwick.

DUCK EXTRA PRIZES (Any variety).—First, Messrs. Gunson and Jefferson. Second, R. Leech. Third, T. Wakefield.

ORNAMENTAL WATER FOWL.—First, J. Jennison (Black Swans). Second, S. A. Wyllie, East Mousley, Surrey (Mandarin Ducks). Third, J. Jennison, Belle Vue, Manchester (Carolinas). Highly Commended, A. O. Worthington, Burton-on-Trent (Fancy Geese and Canadian Geese); E. Longton; Mrs. C. W. Brierley, Middleton, Manchester (Mandarins); J. Jennison (Mandarins, Shieldrakes, Pintail, Barnacle Geese, Brent Geese).

GEESE (White).—First, Messrs. J. & W. Rostron, Levenshulme, Manchester. Second, W. Gamon, Chester. Third, R. Harper, Reddish, near Manchester. Commended, Messrs. J. & W. Rostron.

GEESE (Grey and Mottled).—First, J. K. Fowler. Second, S. H. Stott, Quarry Hill, Rochester. Third, Rev. W. J. Mellor, Colwick Rectory, near Manchester. Highly Commended, J. Hardie.

TURKEYS.—First, E. Leech, Rochdale. Second, Mrs. Dale. Third, J. Smith, Breeder Hills, Grantham. Highly Commended, F. E. Richardson, Bramshall, Uttoxeter; S. Lang, jun., Barrow, near Bristol; S. H. Stott; R. Leech, Rochdale. *Poults.*—First, E. Leech. Second, J. Smith. Third, Mrs. Dale. Highly Commended, Miss Davies; J. Anderson; F. E. Richardson; J. Hardie; E. Leech.

EXTRA STOCK (Any variety of Fowls not before named).—First and Second, S. A. Wyllie (La Flèche and Houdan). Third, Col. Stuart Wortley (French Fowls).

HAMBURGH (Black).—First, C. Sidgwick, Keighley, Yorkshire. Second, G. Lingard, jun., Selly Oak, Birmingham. Commended, R. S. Moore, Gateacre, near Liverpool. *Chickens.*—First, J. Lancashire, Tonge, Chadderton, near Manchester. Second, J. Fielding, Newchurch, near Manchester. Very Highly Commended, R. Goodwin, Middleton, Manchester. Highly Commended, J. Jackson, Bury, Lancashire. Commended, J. Harrop, Middleton, Manchester; G. Lingard.

HAMBURGH (Golden-pencilled).—*Chickens.*—First, T. Wrigley, jun., Tonge, Middleton. Second, J. E. Powers, Biggleswade, Bedfordshire. Third, F. J. Astbury. Highly Commended, H. Beldon. Commended, T. Walker, jun., Denton, near Manchester. *Cock.*—First and Third, T. Wrigley, jun. Second, A. Bamford, Tonge Lane, Middleton. Highly Commended, R. MacGregor, Perth, N.B.; J. E. Powers; W. Hargreaves, Bacup, Lancashire.

HAMBURGH (Silver-pencilled).—*Chickens.*—First, H. Beldon. Second, J. Walker, Haya Park, Knaresborough. Third, T. Sharples, Rawtenstall. Highly Commended, J. Thresh. *Cock.*—First, H. Beldon. Second, T. Sharples. Highly Commended, J. Parr, Barton-on-Irwell. Commended, B. Bee.

HAMBURGH (Pencilled).—First, A. O. Worthington. Second, J. E. Powers.

PENCILLED HAMBURGH EXTRA PRIZES (Either variety).—First, J. E. Powers. Second, H. Beldon.

HAMBURGH (Golden-spangled).—*Chickens.*—First and Second, J. Rae, Abfield, Manchester. Third, N. Marlor, Darton, Manchester. Highly Commended, J. Buckley, Taunton, Ashton-under-Lyne; J. Andrew, Waterhouses, Ashton-under-Lyne; J. Ogden; T. Scholes, Hollinwood.

Manchester; E. Brierley. Commended, W. Horton; J. Buckley; W. A. Hyde; T. Scholes; J. Parr; H. Carter, Upperthong, Holmfirth; J. Walker. *Cock*.—First, J. Ogden Second, T. Walker, jun Third, W. A. Hyde, Ashton-under Lyne Highly Commended, J. Roe; J. Buckley; N. Marlor. Commended, E. Brierley; H. Carter.

HAMBURGH (Silver-spangled).—*Chickens*.—First, J. Fielding. Second, J. A. Taylor. Third, J. Walker. Highly Commended, H. Beldon; J. Lancashire. Commended, J. Fielding; J. Jackson; Mrs. A. Hurt. *Cock*.—First, T. Sharples. Second, J. Fielding. Commended, T. Wrigley, jun.

HAMBURGH (Spangled).—*Hens*.—First, J. Ogden. Second, J. Roe. Very Highly Commended. T. B. Hartley; J. Fielding Highly Commended, T. Scholes; N Marlor; J. Walker Commended, J. Buckley.

SPANGLED HAMBURGH EXTRA PRIZES.—First, N. Marlor. Second, J. Andrew.

GAME BANTAMS (Black-breasted and other Reds).—First, J. Fryer, Staveley, Derbyshire. Second, J. Crosland, jun. Third, G. Smith. Fourth, J. W. Morris. Highly Commended, H. Ashton, Polefield, Prestwich; D. Parsons; G. R. Davies; Miss E. A. Crawford. Commended, Sir St. G. Gore, Bart.; A. Fenton; J. Holme; R. MacGregor.

GAME BANTAMS (Any other variety).—*Chickens*.—First, J. Crosland, jun. Second, Sir St. G. Gore, Bart. Third, Rev. W. J. Mellor.

GAME BANTAM.—*Cocks*.—First, J. Barr, Swan Island, Atherton, near Manchester. Second, Mrs. C. W. Brierley. Third, J. Crosland, jun. Fourth, G. Griggs Highly Commended, F. L. Roy, jun.; A. Fenton; J. A. Taylor; Miss E. A. Crawford. Commended, Sir St. G. Gore, Bart.; G. R. Davies; W. Parker.

GAME BANTAM (Any variety).—*Hens*.—First, S. Lang, jun. Second, W. M'Connell. Commended, J. Anderson.

GAME BANTAM EXTRA PRIZES (Any variety).—First and Third, D. Parsons. Second, J. Barr.

BANTAMS (Any variety except Game).—First, A. K. Briggs (Black Bantams). Second, M. Leno (Gold-laced). Third, G. Griggs (Speckled-booted Bantams). Highly Commended, F. L. Roy, jun. (Silver-laced Sebright); H. Ashton (White-booted); J. W. Morris (Black Bantams).

PIGEONS.

POWTERS (Any colour).—First, J. Thackray, Petergate, York. Second, F. Crossley, Elland, near Halifax. Highly Commended, J. K. Harvey, M.D, Cork; E. E. M. Royds, Greenhill, Rochdale.

CARRIERS (Black).—*Cock*.—First, J. Firth, jun., Webster Hill, Dewsbury. Second, F. Crossley. *Hen*.—First and Second, F. Crossley.

CARRIERS (Any other colour).—*Cock*.—First, G. H. Roberts, Penwortham, Preston. Second, A. Mangnall, Broughton. *Hen*.—First, J. Hawley, Bingley, Yorkshire. Second, A. Lowe, Over Hutton, near Bolton. *Young Birds*.—First, J. Hawley. Second, F. Else, Westbourne Grove, Bayswater, London. Third, G. H. Roberts. Commended, M. Hedley, Claremont Green, Redhill, Surrey.

DRAGONS.—First, H. Yardley, Market Hall, Birmingham. Second, J. Percivall. Highly Commended, H. Yardley. Commended, F. Crossley.

ANTWERPS.—First, S. A. Taylor, Sutton Coldfield, near Birmingham. Second, J. Hawley. Highly Commended, S. A. Hawley.

JACOBINS (Any colour).—First, T. H. Ridpeth, Rusholme. Second, J. Mur, Glasgow. Commended, A. Mangnal

NUNS.—First, F. Else. Second, C. Bulpin, Bridgewater, Somerset. Commended, H. B. Whittaker, Alkrington, Middleton.

RUNTS.—First, T. D. Green, Saffron Walden, Essex. Second, E. E. M. Royds, Greenhill, Rochdale. Highly Commended, H. Yardley.

BARBS.—First, J. Gell, York. Second, J. Thackray. Highly Commended, J. Fielding, jun., Rochdale. Commended, J. Thackray.

TURBITS.—First, J. Thackray. Second, C. Bulpin. Highly Commended, J. Hawley.

OWLS.—First, F. Crossley. Second, J. Fielding, jun. Highly Commended, J. Fielding, jun.; J. Baily, jun.

TRUMPETERS.—First, J. Hawley. Second, W. H. C. Oates, Besthorpe, Newark, Notts. Highly Commended, J. Firth, jun. Commended, J. Thackray.

FANTAILS.—First and Second, H. Yardley. Highly Commended, F. Else.

TUMBLERS (Almond).—First, J. Thackray. Second, R. Fulton, Deptford. Third, F. Crossley.

BEARDS.—First, J. Thackray. Second and Highly Commended, W. H. C. Oates.

BALDS.—First, T. H. Ridpeth. Second, J. Fielding, jun. Highly Commended, J. Hawley.

TUMBLERS (Any other variety).—First, J. Thackray. Second, R. Fulton. Highly Commended, J. Fielding, jun.; E. E. M. Royds

ANY OTHER VARIETY NOT BEFORE NAMED.—First, Third, and Highly Commended, J. Baily, jun. (German Toy, Archangels, and Austrian Powters). Second, H. Yardley.

DOVES (Any variety).—First, Second, and Highly Commended, J. Jennison, Zoological Gardens, Manchester (Chinese Doves, French Doves, and Stock Doves).

RABBITS.

BLACK AND WHITE.—First, J. Read, Coventry. Second, W. Newsome, Leeds.

YELLOW AND WHITE.—First, W. Stelfox, Greenheys. Second, J. Taylor, Sheffield.

TORTOISESHELL.—First and Second, G. F. Jones, Bootham, York. Highly Commended, H. Handford, Wilford, Notts.

BLUE AND WHITE.—First, G. F. Jones Second, W. Newsome.

GREY AND WHITE.—First, W. Stelfox. Second and Highly Commended, H. Handford.

SELF-COLOUR.—First, J. Taylor. Second, J. Reed. Highly Commended, H. Handford.

LONGEST EARS.—First, W. Newsome. Second, G. Mellor, Macclesfield. Highly Commended, E. E. M. Royds, Green Hill, Rochdale

ANGORA.—Prize, A. Parry, Rochdale. Highly Commended, C. Rayson, Prestwich, Manchester.

OTHER FOREIGN RABBITS.—First and Highly Commended, S. A. Wylie, East Moulsey, Surrey (Leporides). Second, D. Barker, Cheadle Hulme (Himalayan).

JUDGES.—*Dorkings, Spanish, Cochins, Brahmas, and Crève Cœurs:* Mr. Edward Hewitt, Sparkbrook, Birmingham, and Mr. W. B. Tegetmeier, Muswell Hill, London. *Game, Game Bantams, &c.:* Mr. J. H., Smith, Skelton Grange, York, and Mr. R. Teebay, Fulwood, Preston, *Hamburghs, Polands, Ducks, &c.:* Mr. James Dixon, North Park Bradford, and Mr. S. Fielding, Trentham. *Pigeons:* Harrison Weir, Esq., Peckham, London, and T. J. Cottle, Esq., Cheltenham. *Rabbits:* Mr. Henry Yardley, Market Hall, Birmingham.

HECKMONDWIKE POULTRY SHOW.

DECEMBER 26TH.

A GOOD number of first-class birds were exhibited, and the visitors seemed highly gratified while examining the various classes of birds shown. The Committee consider the Exhibition a success, and feel in a measure repaid for the labour bestowed in connection with it.

GAME (Black-breasted Red).—First, Extra, and Second, G. Noble, Staincliffe. Highly Commended, W. Fell, Adwalton.

GAME (Brown-Red).—First, J. Hodgson, Bowling Old Lane, Bradford. Second, H. C. Mason, Drighlington. Highly Commended, W. H. Robinson, Long Lee, Keighley; T. Kilburn, Batley Carr. Commended, J. Ineson, Staincliffe.

GAME (Duckwings and other Grey and Blue).—First, W. Fell. Second, C. Smithson, Heckmondwike. Highly Commended, W. Kellett, New Road, Birstal; J. Elam, Heckmondwike. Commended, W. Fell.

GAME (White and Pile).—First H. C. Mason.

GAME (Black and Brassy-winged).—First J. Ineson. Second, J. Ibbotson, Gomersal.

GAME BANTAM (Red).—Extra Cup and First, C. Clegg. Second, G. Noble.

GAME BANTAM (Duckwing).—First, J. Hirst, Hillhouse, Heckmondwike. Second, J. Elam. Highly Commended, J. Ibbotson; H. Shepley, Carlinghow. Commended, — Armitage, Gomersal.

BANTAM (Black).—First, J. Parker, Heckmondwike. Second, S. Schofield, Heckmondwike.

SPANISH (Black).—First, W. H. Charlesworth, Newhouse, Huddersfield.

HAMBURGH (Golden-spangled).—First, H. Firth, Dudley Hill, Bradford. Second, J. F. Loversedge, Newark, Notts.

HAMBURGH (Pencilled).—First, J. Ibbotson.

COCHIN-CHINA.—First, H. Firth Second, S. Schofield.

ANY OTHER DISTINCT BREED.—First, P. Greenwood, Rawfolds, Cleckheaton.

GAME (Red).—First, W. Fell. Second, G. Noble.

GAME (Any colour).—*Hen*.—First, — Suddick, Tong Street, Dudley Hill, Bradford. Second, G. Noble.

EXTRA.—First, J. Brooke. Second, G. Noble. Eighly Commended, J. Elam; J. Beaumont.

JUDGES.—Mr. J. W. Thompson, Southowram; Mr. Enoch Hutton, Pudsey; and Mr. Mason, Rochdale.

MUNSTER POULTRY SHOW.

ON December 20th, the Exhibition of Poultry, Pigeons, song and ornamental birds was opened in the new market, which was appropriately decorated for the occasion. The pens were arranged on stands in rows, so as to give intermediate space between each row for a promenade, enabling the visitor to see every bird in the Exhibition.

The entries amounted to 444, and the Exhibition was decidedly the finest of the kind ever held in Munster, or perhaps in Ireland, and in the opinion of the gentlemen selected to judge of the merits of the various classes, is highly creditable to Limerick.

The department for Pigeons, singing and ornamental birds, was a source of the greatest attraction. Mr. Corbett, of Castleconnell, exhibited a complete aviary, composed of foreign and native birds, both song and ornamental, and it is not too much say his birds would form an exhibition in themselves, for this gentleman has perhaps the finest private collection of this kind in Ireland.

In the *Pigeon* classes there was a keen competition in consequence of the superior quality of those exhibited. Mr. A. W. Shaw gained the medal for the greatest number of points in Pigeons, and Mr. Perrott, of Cork, won the silver cup for the best pair of Powters of any age or colour. The collections of those gentlemen were very extensive, and remarkable for the beauty exhibited by the birds they contained, and they likewise were great objects of attraction to visitors, particularly to connoisseurs. In the poultry department the entire collection was worthy of admiration; and to those who are not rearers of fowl it showed to what perfection those birds required for domestic use can be bred, and how lamentably deficient Ireland has been hitherto in their rearing. Now that this Exhibition has been so great a success, let us hope that it will lead to the establishment of a permanent Society in Limerick, so that in the course of a few years it will not only take the lead in this country, but that it will result in establishing annual exhibitions of all kinds of fowl equal in extent and breed with the most favoured ones in England. Ireland is eminently adapted for being a first-class fowl-breeding country; and we see no obstacle that could not be overcome in having as good a breed as that which exists in England.—(*Chronicle*).

DORKING (Coloured or Silver-Grey).—First, F. W. Zurhorst, Belville Donnybrook. Second, R. P. Williams, Clontarf, Dublin. Highly Commended, J. C. Cooper, Limerick. Commended, Mrs. Fosberry, Clorane, Kildimo; T. O'Grady, Roughgrove, Bandon. *Chickens*.—First, T. O'Grady. Second, Major Vandeleur, Limerick. Highly Commended, F. W. Zurhorst; J. C. Cooper. Commended, T. O'Grady.

SPANISH.—First, R. P. Williams. Second, J. C. Cooper. Highly Commended, Miss E. de C. Drevar. Commended, A. Comyns, jun. *Chickens*.—First, A. Comyns, jun. Second, R. P. Williams. Commended, R. P. Williams; J. C. Cooper.

GAME (Black or Brown-breasted).—First and Second, J. C. Cooper. Commended, J. Purcell, Carrig.

GAME (Any other variety).—First, A. E. Allen, Cork. Second, J. C. Perry, Browning's Town, Cork.

COCHIN-CHINA (Cinnamon or Buff).—First and Second, F. W. Zurhorst. Highly Commended, R. P. Williams. Commended, F. W. Zurhorst.

COCHIN-CHINA (Brown or Partridge-feathered).—First, C. F. Staunton, Clondalkin. Second, J. C. Fitzgerald, Abingdon House, Murroe.

COCHIN-CHINA (White or Black).—First and Second, F. W. Zurhorst. Highly Commended, A. Comyns, jun.

BRAHMA POOTRA (Dark).—First, R. W. Boyle, Bray, Co. Wicklow. Second, J. C. Perry. Highly Commended, J. C. Cooper.

LA FLÈCHE.—First, F. W. Zurhorst. Second, J. C. Cooper.

MALAY.—First and Second, J. C. Cooper.

CRÈVE CŒUR.—First, J. C. Cooper. Second, D Sullivan, Ballybrown.

HOUDAN.—First, F. W. Zurhorst. Second, J. C. Perry. Commended, J. C. Cooper.

SULTAN FOWL.—First and Highly Commended, F. W. Zurhorst. Second, J. C. Cooper.

WHITE-CRESTED BLACK OR BLACK-CRESTED WHITE FOWL.—First and Second, Miss E. de C. Drevar.

GOLDEN OR SILVER-CRESTED FOWL.—First and Second, W. Sylvester, Sheffield. Highly Commended, R. P. Williams.

HAMBURGHS (Golden or Silver-pencilled).—Prize, F. W. Zurhorst.

HAMBURGHS (Golden or Silver-spangled).—First, J. C. Perry. Second, R. P. Williams.

GAME BANTAMS.—First and Second, C. F. Staunton, Castleconnell. Commended, W. Corbett; J. Lloyd, Warren's Place, Cork.

BANTAMS (Any other variety).—First, Miss F. Croker, Ballynagarde, Limerick. Second, F. W. Zurhorst.

ANY OTHER VARIETY OF FOWL.—First, W. Corbett. Second, J. C. Perry. Commended, R. Wheeler; Capt. Gilbert, Killaloe.

DUCKS (Rouen).—First, R. P. Williams. Second, T. Hollis, Reading. Third and Highly Commended, J. C. Cooper. Commended, Lady Clarina, Elm Park, Clarina.

DUCKS (White Aylesbury .—First and Third, F. W. Zurhorst. Second, R. P. Williams. Highly Commended, F. W. Zurhorst; R. P. Williams; D. O'Grady. Commended, J. C. Cooper.

GEESE (White).—First and Second, J. C. Cooper. Third, W. Corbett. *Goslings.*—First and Second, J. C. Cooper. Third, S. F. Dickson, Vermont, Limerick.

GEESE (Grey and Mottled).—First and Second, J. C. Cooper. *Goslings.*—First and Second, J. C. Cooper. Third, T. Costelloe, Murroe. Commended, J. C. Cooper; S. F. Dickson.

TURKEYS.—First, T. Hollis. Second, F. W. Zurhorst. *Poults.*—First and Second, J. C. Cooper. Third, Mrs. E. E. Llewellyn.

SELLING CLASS (Any distinct variety).—First and Second, Capt. Gilbert. Third Mrs. Webb, Knocklong. Highly Commended, R. P. Williams; Capt. Gilbert; J. C. Cooper. Commended, J. Christie; Capt. Gilbert; J. C. Cooper.

Cup (value five guineas), for the greatest number of points in poultry, J. C. Cooper.

SINGLE COCKS.

DORKING (Any colour).—First, D. O'Grady, Ballynorth, Pallaskenry. Second, R. P. Williams. Commended, J. C. Cooper.

SPANISH.—Prize, J. Bresnahan, Limerick.

GAME.—First, J Downey, Garvey's Range. Second, P. Mack, Newtown.

COCHIN-CHINA.—First and Second, F. W. Zurhorst.

BRAHMA POOTRA.—First, R. W. Boyle. Second, F. W. Zurhorst.

COTTAGERS' PRIZES.

ANY DISTINCT BREED.—First and Third, J. Christie, Ballybrown. Second, P. Enright, Muckinich. Fourth, Mrs. M. Switzer, Clarina.

DUCKS.—First, Mrs. M. McMahon, Cooper Hill. Second, T. McMahon. Third, Mrs. M. Switzer.

PIGEONS.

POWTERS Yellow, Red, Mealy, or other colour).—First, J. H. Perrott Cork. Second, A. W. Shaw, Limerick. Highly Commended and Commended, A. W. Shaw; J. H. Perrott.

POWTERS (Black-pied and Blue).—First and Second, J. H. Perrott. Highly Commended, Dr. Harvey, Cork; J. H. Perrott. Commended, J. H. Perrott.

POWTERS (White).—First, Dr. Harvey. Second, J. H. Perrott. Highly Commended, A. W. Shaw.

CARRIERS (Black).—First and Second, G. Wherland, Cork. Very Highly Commended, G. Wherland. Highly Commended, A. W. Shaw. Commended, A. W. Shaw; Dr. Harvey.

CARRIERS (Dun).—First and second, G. Wherland. Highly Commended, A. W. Shaw.

CARRIERS (Blue or other colour).—Second and Highly Commended, A. W. Shaw.

SHORT-FACED TUMBLERS (Almonds).—First, Dr. Harvey. Second, A. W. Shaw. Very Highly Commended and Highly Commended, A. W. Shaw.

SHORT-FACED TUMBLERS (Kites or whole feathers).—First and Second, A. W. Shaw.

SHORT-FACED TUMBLERS (Mottles or other colour).—First and Second, A. W. Shaw.

COMMON TUMBLERS (Balds or Beards).—First, Second, and Commended, A. W. Shaw.

COMMON TUMBLERS (Ermine or Fawn-booted).—First and Second, C. Cooper, Cooper Hill, Limerick.

BARBS (Black).—First, G. A. Wherland. Second, C. F. Staunton. Highly Commended, G. A. Wherland; J. H. Perrott.

BARBS (Any other colour).—First and Second, J. H. Perrott. Commended, G. A Wherland.

JACOBINS (Red or Yellow).—First and Second, J. H. Perrott Commended, C. F. Staunton; J. Lloyd; T. O'Grady.

JACOBINS (Any other colour).—First, and Second, T. O'Grady.

FANTAILS (White .—First, J H. Perrott. Second, C. F. Staunton. Highly Commended, J. H. Perrott. Commended, T. O'Grady.

FANTAILS (Any other colour).—Prize, J. W. Edge, Birmingham.

OWLS (Blue or Silver).—First, C. F. Staunton. Second, J. H. Perrott.

OWLS (Any other colour).—First, A W. Shaw. Second, J. W. Edge.

TRUMPETERS (Mottles).—First, J. H. Perrot. Second, A. W. Shaw. Highly Commended, J. H. Perrott.

TRUMPETERS (Any other colour).—First, C. F. Staunton. Second, T. O'Grady.

TURBITS.—First, A. W. Shaw. Second, F. Waitt, Sparkbrook, Birmingham. Highly Commended, F. Waitt. Commended, C. F. Staunton; T. O'Grady.

NUNS.—First, T. O'Grady. Second, A. W. Shaw.

ANY OTHER VARIETY OF MERIT.—First, J. Lloyd. Second, J. H. Perrott (Brunswicks). Extra Second, W. Corbett. Highly Commended, F. Broemel, Ladywell, Kent; F. Waitt; J. W. Edge. Commended, F. Waitt; J. Lloyd

FOR THE BEST PAIR OF POWTERS (Any age or colour).—Cup, J. H. Perrott.

MEDAL.—A. W. Shaw.

CANARIES.

YELLOW (Belgian).—First and Second, W. Corbett. Commended, T. Fitzpatrick, Catherine Street, Limerick.

BUFF (Belgian).—First, Mrs. La Touche, Newbridge, Co. Kildare. Second, W. Corbett.

VARIEGATED (Belgian).—First and Second, Mrs. La Touche.

CRESTED OR OTHER VARIETIES.—First and Second, W. Corbett. Highly Commended, Mrs. La Touche; Miss F. Croker, Ballynagarde, Limerick. Commended, Mrs. La Touche.

GOLDFINCH MULE.—First and Second, Hon. E. Roche, Whitegate, Cork. Highly Commended, J. Lynch, Limerick. Commended, Miss F. Croker.

LINNET MULE.—Prize, C. Cooper.

ORNAMENTAL WATERFOWL.—First, Second, and Third, R. P. Williams.

ORNAMENTAL BIRDS.—Highly Commended, W Corbett.

The following were the Judges:—*Poultry and Pigeons:* Mr. P. Jones, Fulham, London; *Small Birds:* Mr. James Keating, Cork; Mr. John Donoghue, Limerick.

HIVE OVERTURNED.

AN accident has happened in my apiary which has doubtless occurred to many others. The night of the 13th-14th of December was very boisterous here, and after long-continued rains the ground had become much and deeply saturated; on Friday morning the news was brought me that a stock of bees had been blown over, and I found my only remaining primitive hive standing out on a post driven into the ground had come to grief, the pedestal having given way with the weight. The hive with its contents, after having rolled 12 or 14 yards down an inclined plane, had fortunately righted itself as to position, and the poor bees, ever ready to make the best of matters, had collected and clustered, with the exception of those crushed and a knot on the two or three bits of comb that had tumbled out in the descent, on the only comb that had not been detached, and which remained up inside the hive. The great mass of ruin was on the ground under the hive, the honey of course running out.

Having ascertained the state of affairs, I called to my gardener to bring his spade, and, making it quite clean, we pushed it under the comb and hive, and in that manner lifted the lot on to a floor-board, and carried it to another stand near to its former place, but more secure. We then placed a tea-tray under the lip or landing-board to catch the honey that was draining out, and on this, an inch or so above its surface, a piece of perforated zinc to give the bees that might come out with it a chance of escape from drowning. I then left them until the evening, when I took away the floor-board with the great mass of *débris*, and put in its place a clean dry one with some sealed combs of honey, to enable the bees to go in and out with safety. On Saturday there was a great commotion cleaning up the outside honey, not only by the rightful owners, but also, I feared, by robbers from stocks not far distant; and yesterday, to be certain, I placed more honey outside, and soon perceived proof of their being robbed, some slaughter being caused by fighting, although the thieves had the worst of it.

I now propose feeding by filling a short-necked water-bottle with honey and sugar, tying muslin or the like over the opening, and placing it inverted in the hole at the top of the hive, cut for supering. Will this plan, by giving the necessary quantity of food, save the bees? (I could not see the queen among the two or three hundred killed, so trust she is safe), or could you under the circumstances suggest a better plan?—A. T.

[With only one comb remaining in the hive and at this season, a fatal issue appears almost inevitable. Still, with the exceptionably mild weather we are now experiencing, and in the genial climate of Jersey, the poor bees may possibly have the ghost of a chance; but in order to enable them to avail themselves of it, food should be given in a wide-mouthed pickle-bottle, which should be perseveringly refilled as rapidly as it is emptied. The stock would, however, have a better chance of surviving if the broken combs were pieced together, and the whole fitted into frames and retained therein by means of strips of wood, zinc clips, or any other mode which your ingenuity may suggest. When the job is complete, the combs

should be placed in a hive, and the bees either knocked out or brushed from their present domicile on to the top of the frames, whence they will find their way down between the combs. The remaining comb should now be cut out of the old hive, fitted into a frame, and added to the others, and, the crown-board being put on, the hive should be placed on the old stance. After the expiration of two days, advantage should be taken of the first few hours of mild weather to open the hive and remove the artificial supports from all the combs which have been fixed by the bees, after which the necessary supply of food must be furnished as rapidly as possible by means of an inverted pickle-bottle.]

SWARMS DESERTING THEIR HIVES.

I FIND in page 476 a few remarks on the subject of bees leaving one of Neighbour's hives shortly after they were hived, which appears in your opinion to have been caused by the smell of the wood. I cannot say that I coincide in this idea. I had once two swarms which were put into two straw hives in one day, but to my mortification they deserted their hives a few hours after being hived and flew away. This took place in my early days, but since then I have not in one instance had any difficulty of this kind to contend with, although I have hived several hundreds of swarms, some of which I have put into wood, straw, and glass hives. I have also stocked Nutt's collateral boxes, Woodbury bar-frame boxes, Stewartons, Langstroths, and boxes invented by myself known as Addey's ten-bar sliding boxes, likewise Neighbour's and other kinds, of which some were newly painted inside, and others not painted at all. I once put swarms into some straw hives which were sewn with tarred twine and used as soon as made; but I have not in one instance had the bees leave after hiving since I made a practice of cementing wax inside at the top in such a way that the bees can attach their combs to it. With irons made expressly for the purpose I cement a bit of comb to the top before hiving, and in boxes which contain bar-frames I coat them with wax inside, and fix small bits of combs under the top part of each bar; by so doing I have escaped the difficulty which many apiarians have had to contend with.

I may add, that I admire the humane principle, having during the last autumn taken not less than two hundred stocks of condemned bees in this neighbourhood to make unions of, and I shall always feel it a pleasure to impart information on the humane system of management.—THOS. ADDEY, SEN.

HOW LONG MAY A ROYAL CELL REMAIN SEALED?

I NOTICED a singular circumstance in raising queens this year. After having supplied a queenless stock with some brood-comb under a bell-glass on the top of the hive, as is my custom, three queen cells were started, one of which was sealed over in thirty hours after it had been commenced, whilst the other two were not sealed till four days after, and both emerged from their cells on the twelfth day; yet, strange to say, the one that was first sealed was not hatched until the fourteenth, being about eleven and a half days after being sealed.—A LANARKSHIRE BEE-KEEPER.

OUR LETTER BOX.

YORKSHIRE SOCIETY'S POULTRY SHOW.—The first prize for Cochin-China (Yellow or Buff), was awarded to Henry Steward, Laurel Villa, Bishopsthorpe, York.

ANALYSES OF EGGS (*W. H. M.*).—We are obliged by your communication; but we have several much fuller and more particular analyses by Dr. Prout and others.

GAME FOWLS (*Query*).—"I do, of course, include hens in stating that Brown Reds stand first for shape and carriage. The best Game hens are the Dark Grey and Brown Red hens, with dark combs and faces; these are always the gamest and hardest. If by Blood hens is meant Red Blood hens, which is the correct meaning, the hens of the Cheshire Piles, and the White-legged wheaten hens are the best, as described by me in page 436, together with the other red-eyed breeds there mentioned. Game hens should be short in body, and rather upright and erect, with sloping backs. Hens carrying their backs level or horizontal are less spirited birds. The sportsmen's breeds described by me lately are all the best breeds for spirit. I mean to give some further notes on Game fowls, if possible, soon; on judging and breeding them first. Having visited Batavia in Java, Singapore in Malacca, and the coast of China in 1849 and 1850, and Spanish America previously, I can also give some notes on the wild Indian breeds, and on the sorts used for fighting in those countries, such as Gallus Bankiva, Sonneratii, giganteus, æneus, furcatus, Stanleyi, Jungle Fowl, Firebacks, and a few other foreign breeds. Should "QUERY" wish to write to me privately he can have my address, and I will willingly answer his queries to the best of my ability. There were two slight errors or misprints in my article in page 436. In Dark Black-breasted Reds 'clear-hackled' is spelt 'clean-hackled;' and in Red Duns 'dark shade' is made 'dark shape' as to the legs.—NEWMARKET."

KEEPING POULTRY PROFITABLY (*F. J. C.*).—Mr. Brent in his notes upon this subject, meant that if eggs only were desired he would recommend White Dorkings to be kept. If chickens only, then Brahma Pootra hens and a Houdan cock. To keep the breeds pure if allowed to run together in a farmyard would be impossible. We have found for both eggs and chickens either Dark Cochin-China or Brahma Pootra pullets and a coloured Dorking cock were productive.

VARIOUS (*F. T.*).—We never give salt to fowls. Citrate of iron is only given to individual fowls afflicted with leg-weakness. Four grains daily is the dose. If bruised oats are the food given to fowls, and they have a good grass run, there is no need for soft food, except that a change occasionally is always desirable.

PRODUCTION OF EGGS, &c., (*Aliquis*).—We published Mr. Brent's notes, and you will see an answer to-day to another correspondent. It is not usual for a Grey Dorking cock to lose all his black feathers and become quite white the third year. Many poultry-breeders in 1867 will keep journals who never kept them before, and we hope will send us the results of their experience.

POULTRY RUN GLAZED (*Frances*).—Do not have it heated. Being glazed it will be quite warm enough for early chickens, even in the severest weather.

LEG-WEAKNESS (*Constant Subscriber*).—The weakness you speak of, apparent in your Houdan cockerel, is unusual at this time of year, or in the breed you keep. We therefore seek for some other cause. Is your poultry-house paved, bricked, or boarded? Either would cause it. There is no healthy flooring to a poultry house but earth. Either of the floors we have mentioned causes an unnatural action of the feet (toes), and they induce cold in the limbs, which causes the weakness you complain of. At this season of the year you have little hope of a cure; but if the bird promises well, and you wish to save him, put him in a small place on oat-straw, feed on oatmeal slaked with strong ale, and give him raw eggs to eat. Break the shell in half, and let him have the yolk only. Give him also cooked meat chopped fine. Feed very frequently, and a little at a time.

CROOKED BREASTS (*F. N.*).—We are not responsible for the omissions of the "Standard of Excellence." The crooked breast-bone of your Dorking cockerel may be hereditary, or it may arise from quick growth and narrow perches. It is always a bad sign, and we should not breed from a bird that had it. Where a fast-grown, and consequently weak bird roosts on a narrow perch, it lacks the power to support the body by the clasp of the feet, and from very lassitude the breast rests on the perch. At an early age, being only a gristle, it takes the impress of it.

EGGS LAID AT THE BIRMINGHAM SHOW (*J. L. A.*).—Those who frequent the Birmingham Show cannot fail to have observed the men who go about to collect the eggs. Every one is broken the moment it is seen. It has been attempted to purloin them, but the offenders have always been given into custody.

GAME COCKS (*A Subscriber*).—We can give you no rule for preventing Game cocks fighting. Many have tried it: none have succeeded. It is their nature. They may be separated for a time by the following process:—When two are determined to fight, let two persons take a long rod each, and at the end fasten an empty bag or pillow-case. As soon as the birds are sparring closely, each person must choose one of the two cocks and buffet him well with the empty bag. They will leave off fighting, but the process must be frequently renewed.

VARIETIES RUNNING TOGETHER—PROPORTION OF THE SEXES (*E. M. B. A.*).—Separate your fowls at once. There is no certainty after the new year begins. In breeding for exhibition a cock should not have more than three hens in January. As the weather gets warmer and the days become longer the number may be increased. The disappointment in early eggs is caused by the neglect of this rule.

BANTAMS WITH COCHIN-CHINAS—WHITE COCHIN-CHINAS (*Martyn*).—We speak under correction. We have for many years kept Bantams and Cochin-Chinas together. We have never had the suspicion of any bad results; others will tell you differently. No coloured feather of any hue is admissible in the saddle of a White Cochin cock of any age.

FOWL'S WING CUT—HAMBURGH'S COMBS (*H. C. G.*).—A cut wing is a disqualification. The comb of a Hamburgh must not only be quite upright, but firm on the head.

BARBS AT YORK SHOW.—Your correspondent is labouring under a mistake in writing that my birds were so highly dressed that one of them was nearly blind before leaving the Show. It was merely the effect of cold. The bird's eye had not even been bathed with anything except water. I hope you will oblige me by inserting this, and clear me from what amounts to a charge of cruelty.—E. E. M. ROYDS.

WILTSHIRE MODE OF CURING BACON (*B. B.*).—Directions for an eight-score pig:—Lay the flitches on a long wooden tray, slightly tilted for the brine to run out of a hole made in one corner. In Wiltshire there are always four chines; lay everything in the tray. Allow one stone of salt, one pound of saltpetre, half a pound of bay salt. Mix all in a pan, and rub in at first daily, and after the first week every other day for a month. At the end of that time rub the flitches with bran, and hang them up in a dry kitchen, with a stick placed between them and the wall.—A WILTSHIRE LADY.

POULTRY MARKET.—DECEMBER 31.

WE have had a curious Christmas market. There was a good supply and a bad demand in the early stages, and things were reversed at last. Turkeys were sold at high prices on Monday and on the Christmas morning. They monopolise all, and other quotations are not to be made. Now, as at other times, one fact remains apparent—that Turkeys are in a measure, and with rare exceptions, subject to the law of meat, and quality being given, the more that they weigh the more they are worth. This rule is good up to 18lbs.; after that they make fancy prices, and over 20 lbs. every pound adds greatly to value.

WEEKLY CALENDAR.

Day of Month	Day of Week	JANUARY 8—14, 1867.	Average Temperature near London. Day.	Night.	Mean.	Rain in last 39 years.	Sun Rises.	Sun Sets.	Moon Rises.	Moon Sets.	Moon's Age.	Clock before Sun.	Day of Year.

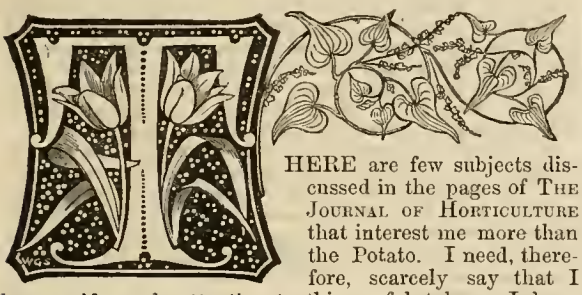
14	M	Primula sinensis.	42.1	29.9	36.0	18	3 8	16 4	52 11	53 0	8	9 16	14

From observations taken near London during the last forty years, the average day temperature of the week is 41.9°; and its night temperature 30.7°. The greatest heat was 54°, on the 9th, 1862; and 12th, 1852; and the lowest cold 6°, on the 8th, 1841 and 1861. The greatest fall of rain was 0.86 inch. N.B.—The Calendar contains the names of plants flowering in the greenhouse.

POTATOES AND THEIR CULTURE.



HERE are few subjects discussed in the pages of The Journal of Horticulture that interest me more than the Potato. I need, therefore, scarcely say that I have paid much attention to this useful tuber. I have read with interest what has been recently written by "D.," of Deal, and Mr. Dobbie, and can corroborate what the former has said about varieties, and what the latter has stated about planting whole sets in preference to cut ones.

Like "D.," of Deal, I consider the Prince of Wales the most worthless Potato imaginable, notwithstanding that it was sent out with the flaming character of being "a boon to the world." Any person who knows a really good Potato would not tolerate it under any circumstances. I also agree with him in considering the Lapstone Kidney the finest in quality of all Potatoes.

I may name, in addition to the five varieties enumerated by "D.," of Deal, the Dalmahoy and American Early, both well-known varieties in Scotland, and first-rate second earlies. They are hardy in constitution, heavy croppers, and excellent in flavour—certainly in all respects not inferior to Daintree's Early.

Ross's Early is an amazing cropper, and of the very best quality, but it requires much room, and is only a third early, eating well all winter.

Myatt's Ash-leaf is with me the heaviest cropper of all the Ash-leaved varieties, and it is fourteen days later than the common old Ash-leaf, yet the best early sort.

The Curly Top, mentioned by Mr. Dobbie, deserves all he has said of it in point of earliness and constitution, but it is a little inclined to be waxy—a great drawback to any Potato.

Touching the chief features in the culture of Potatoes, I have, like Mr. Dobbie, proved over and over again that there is no greater mistake than that of selecting very small sets or of cutting up large Potatoes into many. Any one can put this matter to the test by planting a quarter of Potatoes, beginning at one side, and putting in a row of very small sets, gradually increasing their size in every row till the very largest are planted. It will be found at harvest-time that the small sets give the greatest proportion of small fry, and *vice versâ*, so that when Potatoes are planted whole, medium-sized sets should be chosen. Of the early Kidney varieties I always save sufficient of the very largest tubers I can select, and have ever found them produce the finest crop with the least proportion of small Potatoes unfit for table. The seed should always be saved from the earliest crops, and in garden practice it is a good plan to green them, and store them thinly on shelves in a dry airy place; as soon as they begin to sprout they should be planted the first opportunity.

I consider that the cutting of sets is attended with many evils. The Potato loses much of the sap that should be husbanded. In dry seasons, and particularly in field culture where the ridge system is practised, and the manure ploughed into the centre of the ridge in a dry state, the cut Potato is surrounded with a medium which sucks the sap from it like a sponge, and unless rain set in blanky fields are the result, and the farmer says his Potatoes have taken the "dry rot."

It is not a matter of unfrequent occurrence to see Potatoes first allowed to grow in pits, and then be cut into small pieces, and planted as above; and surely it is a practice which cannot be regarded as anything but most irrational. In garden practice I either plant in soil that has been well manured for the previous crop, or else trench in the manure in autumn, and in doing so mix it well with the whole staple.

One-half the manuring which takes place in field culture I regard as positively mischievous, just because it is generally done in dry weather in April, and when the manure, if not well rotted, becomes dried before it is ridged-in with the plough.

The ridge system itself I look upon as very objectionable on light dry soils. The manure and sets are enclosed in a dry state in an elevated ridge, where the manure when once dry is not easily wetted, and can be of little avail to the crop; indeed, I have seen it turned out in autumn in very much the same state as when it was ridged-in in April. If the sets were planted on the flat instead of in ridges in dry soils it would be the means of producing fine crops, and more especially if the manure were well incorporated with the soil in the previous autumn. The system of grubbing with horse-hoes close to the stems of the crop, loosening the plants about the neck, and, tearing up the stringy roots on which the young tubers are formed, is pernicious in the extreme.

In gardens where the soil is generally rich and deeply worked I think wide planting should be practised. By this means light and air are allowed to play freely about the tops, and the rays of the sun can benefit the soil. For such sorts as Myatt's Ash-leaf, Lapstone, and Daintree's I allow 2 feet 10 inches, and from 12 to 14 inches between the sets; and for larger-topped sorts such as Ross's, 3 feet by 15 inches. I am persuaded that more fine useable tubers are thus produced than when thick planting is practised.

The early varieties, such as the Ash-leaved, may, when planted at such distances, be allowed to grow with two shaws; and the later sorts at the widest distance named sometimes I leave with three without any bad effects. Indeed, if allowed to grow with only one top, such as Ross's Early, are apt to be too large for any purpose, excepting baking whole in their jackets; for this purpose I am required to grow a few of Ross's every year. One season, about three years ago, I took the trouble to weigh twenty-four tubers out of about three barrowloads, and their united weight was 44 lbs., whilst one set reached the enormous

weight of 3¾ lbs. These were sound to the centre, and when baked, came out of their skins sparkling like powdered sugar. They were produced from large Potatoes planted whole and wide, and when turned out the soil looked as if it had been literally paved with Potatoes of enormous size, and there was scarcely a single tuber that could be called small.—D. Thomson.

MAKING VINE BORDERS.

After reading the article by "Vitis" on the construction of Vine borders at page 420 of the last volume, I thought it was really requisite for some one of experience in the matter to make a few remarks as quickly as possible, for what "Vitis" says is calculated to lead people sadly astray, and it is probable that any one about to make Vine borders will be proceeding with the work at once. Therefore, without any apology, I offer the following remarks.

In the first place, I consider it exceedingly presumptuous on the part of "Vitis" to refer to the system proposed by a practical man like Mr. Wills in the jeering way that he does, thus endeavouring to detract from the merit of that method which is not only undeserving of condemnation, but than which, when the exact proportions of the materials are stated, it is impossible to imagine a more correct mode of making a Vine border where the question of expense is no consideration. I do not suppose Mr. Wills for one moment thought his method would meet the requirements of such men as "Vitis." If "Vitis" had politely requested Mr. Wills, stating his means and the object in view, I have no doubt Mr. Wills would have had much pleasure in giving instructions as perfect in their way as the plan which he has already laid down.

With regard to the depth of the border described by Mr. Wills, his provision for airing it and its being composed of such open materials sufficiently remove all objections on that score, especially if it be made 2 feet 6 inches above and the same depth below the ground level, seeing that a foot or 15 inches of the lower portion consists of drainage, so that the layer of turf forming the bottom of the compost will be only 15 inches below the ground level. This, with perfect drainage, will, I am quite satisfied, protect the mass of compost from becoming dank or unhealthy for the roots of the Vines in any part.

I am no advocate for applying bottom heat to Vine borders in the usual way with hot-water pipes, but I cannot see anything but what is right in the way in which Mr. Wills proposes to apply it, the object being merely to keep up a circulation of air around the mass of compost.

After very extensive experience in the formation of Vine borders, I can with confidence strongly recommend Mr. Wills's plan to all who do not mind going to the expense. I am sure Mr. Wills must have bestowed much thought on the subject, and I am sorry he did not make calculations, which I have no doubt he is well able to do, showing the exact proportions of the materials used, as his doing so would have prevented sharp people, who are always ready to point out errors in such a nice way, having the opportunity of doing so. I beg to propose that Mr. Wills shall be allowed to make a chapter of remarks on his own article, to give him an opportunity after more mature deliberation of adding and supplying whatever may be deficient, so as to make it perfectly plain to the most ignorant on the subject. I maintain that the article is a good one, and worth bringing prominently forward so that it may be made perfect.

A few words more respecting the depth of the border. I have found that it is not right to water Vines after the fruit begins to colour, which process lasts about one month, and if the Grapes are wanted entirely for private use it may be a month or two more before the crop is cleared off, during which time the Vines should have no water poured on the roots. As Vines thrive best in very open material, three months, with the shallow borders made entirely inside, and composed of open materials, is too long for the roots to be without water in, it may be, the hottest three months in the year: hence my reason for recommending the deep border, which will retain moisture sufficient for the Vines until water may be applied after the crop is cleared. I would not make the deep border on any account without the provision for airing it.

With regard to the method of making a Vine border described by "Vitis," there is one thing alone in it that in nine cases out of ten would lead to nothing but disappointment and labour in vain. I do not mean to say there would be no Grapes, but in most cases the Vines, if used for early forcing, would be backward at breaking, come on slowly, and at the best be only middling when finished.

How this state of things would be brought about is soon told. The roots of the Vines would go down not only many feet, but yards, out of the influence of the atmosphere, either natural or artificial.

One February I planted some Black Hamburgh Vines, and forced and fruited them the second season. The border was made entirely inside the house on a good floor composed of two layers of bricks grouted in mortar, and was about 3 feet deep. It was composed of fifteen parts of the very best turf from an old pasture, three parts of old lime rubbish, two parts of an excellent quality of sand, as the turf was destitute of sand, but neither heavy nor light, and one part crushed bones, with a little nicely-prepared horse-droppings, just sufficient to make the roots start boldly. It was not hunger that drove the roots from home, yet the Vines during the second season perplexed me sorely, for in many respects they showed indications of their roots having gone down into wrong quarters, which I could scarcely believe to be possible. At the end of the second season the Vines were lifted and removed to another house. I was astonished to find that the roots had found their way through the floor at the bottom, and I traced them 9 feet down below the level of the floor, and then cut them of the thickness of my finger; how much further they went I do not know.

What I want to impress upon the minds of those who are looking out for instructions in the making of Vine borders, is that they should make sure of preventing the roots from rambling away from the prepared border, and how difficult this is to accomplish; and if they are not willing to go to the expense of doing this, to let it alone altogether. I recommend them not to be satisfied with anything less than the following carefully executed.

After the necessary preparations are completed for laying the floor, which should be made before any brickwork connected with the structure is commenced, scrape together in heaps 2 inches of the material forming the bottom, and saturate it with coal tar, which may be procured at a trifling expense from the gas works, if any such exist in the neighbourhood—if not, use another material destructive to the roots of the Vine. Mix the whole well together, let it lie a few days, then spread it all over the bottom again, and upon this place close together a layer of brickbats, or any other material, to the thickness of 3 or 4 inches. The man when putting this down must have a board upon his own work to stand upon; the substance under the layer should be so stiff that it will not ooze up when trodden upon. Next grout the layer all over with mortar so stiff that it will not work up the tar on being spread and brushed about with a broom; then let it remain a few days to dry and harden. The boundary walls and all the walls connected with the structure must have their foundation upon this floor, or if brought from below must have a layer of slates at this level. The boundary walls from the level of the floor must be made so that the roots may have no chance of finding their way through. This may be effected by means of slates put in the middle of the wall, or by leaving a cavity to be filled with a layer of the material used for the bottom of the floor. This may appear to be an unnecessary precaution, but I have found it quite requisite. I have known the roots of Vines go through a floor composed of two layers of bricks, and two brick walls besides, hence my reason for applying something more than ordinary brickwork to secure them, and never in my experience have I lifted Vines without finding that they had wandered away from the prepared border. I do not think Muscats can be grown to perfection without this precaution, but with it, and covering the outside border, they may be fruited as perfectly as the Black Hamburgh—that is, they may be made to produce bunches as full and regular in the berry and finely ripened, the berries being of an enormous size.

"Vitis's" experience of Vine-growing leads him to think that under any circumstances a little drainage is all that is requisite, then again he speaks of the border being trodden upon until it is quite hard. To say the least of it, this is a very loose style of gardening to set before the public.—A Gardener.

At page 481, in your Journal of December 25th, a writer who signs his paper "Forwards" states he has read Mr. Pearson's little book on the Vine, in which he recommends green turf, which he says from many soils would make the worst possible Vine border. I have referred to the work in question, and find the passage stands thus:—"The soil for Vines should be light and porous, and moderately rich, and is better for con-

taining a good quantity of lime. The bulk of it ought to be chopped turf from an old pasture; if neither too sandy nor too heavy, this alone would grow good Grapes. It may be used the day it is cut as advantageously as if kept a year. To ten barrowloads of this turf soil add two of broken oyster-shells, old lime rubbish, or chalk, or a mixture of the three, which is preferable; one of horse-droppings, and half a bushel of broken bones."

Now I would ask, Is the remark of "Forwards" a fair one? Is not the sort of turf soil pretty well indicated in the passage I have quoted from Mr. Pearson's book?—A Lover of Fair Play.

PEAS—QUANTITY OF SEED NEEDED—ESTIMATE OF VARIETIES.

In reply to the question relative to the quantity of Peas sown per acre of kitchen garden; that here is nearly five acres in extent, and there is a large demand for Peas, yet I find 24 quarts ample for the whole season.

Too much cannot be said in favour of Essex Rival and Wonderful. Although Essex Rival is about a week behind Dickson's First and Best in coming in, I depend upon it for large gatherings.

For a first crop I sow in pots in the end of January, harden off, and plant-out the first opportunity, and find the yield to be more than double those from November sowings, and quite as early, to say nothing of the trouble of the latter from mice, &c., and especially from the gardener's feathered friends.

I find the following sorts are as good as any I have tried:—Dickson's First and Best, Essex Rival, Dickson's Favourite, Wonderful, Veitch's Perfection, Hairs' Dwarf Mammoth, and Ne Plus Ultra.—G. E., *Strawberry Hill*.

OUR VINES.

(*Continued from page 6.*)

Through all the winter time, day after day, we looked at our Vines. They were still pale, leafless, unpromising-looking canes, giving no sign of growth, nor even of life. Uncle Tetley peered at them through his spectacles, and papa bought a large magnifier; but yet we could make nothing out. Cousin Herbert took a trowel and turned away the soil from about the Vines. There were lots of little white thread-like roots pushing in all directions; but, then, Cousin Herbert had never seen Vine roots before, and did not know whether they were right or wrong, so I asked George, our gardener, a supposed clever man. "Why, you see, Miss, I never took much notice that way. I am not sure they should be either white or brown, I have seen them both. I don't think it matters much."

February passed, March came—a dry, sunny, blustering month, as much dust in the streets and on the moors as would have ransomed every king in Christendom, our Vines at South Field were out in full leaf; those at Ridge Close had not a leaf to be seen, nor even the least appearance of any swelling of the eyes. "They are dead right out, I am sure," said papa; "I would write to that Bradford man and tell him, if I were you, Herbert;" but Herbert had larger hope and longer patience, so waited on. One morning in the first week of April, a little glistening tear had gathered in the eyes of several of the Vines, and during the same day the had-been-owner walked in.

"What! Your Vines in this state yet?" He took up a syringe and doused them over and over again. It was a regular thunder-storm inside, with heavy rain. How it did run down the glass, carrying with it a good many Yorkshire blacks we did not know to be there. Certainly it was a cleansing operation. Kate timidly suggested the idea of drowning, but he only syringed away the harder, saying, "Do you not know I pledged myself for the success of these Vines? and unless you wish me to fail you will not let them die of thirst. Tell your brother to syringe them night and morning, and during the day while the dry sunny weather lasts, and to water them once a-week, giving them at least three gallons each." Then he took up a watering-can and emptied the cistern that always stood full in the vinery.

After this the Vines grew apace, Cousin Herbert syringing them every morning before he went to his office, and in the evening when he returned, and Kate looking after them during the day. There was no doubt they had wanted water, for in the moist atmosphere they grew amazingly, leaf after leaf unfolding itself in the warm April sunshine. Soft delicate leaves they were, and very beautiful.

One morning going into the vinery we found several of the leaves on the Lady Downe's Vine and one Muscat Hamburgh eaten by some insect, nearly all the young leaves were more or less disfigured; perfectly round holes they were, as if they had been cut out with an instrument. Cousin Herbert said "We must see after it, for the Vines would be injured if not destroyed; if the leaves went wrong the roots would follow, for the leaves are the great root-feeders." Uncle Tetley always laughs at this theory, and calls it absurd, and says, "There never yet were and there never can be leaves without roots." So Kate and I spent much time seeking for something that could have done the mischief. Aunt Margaret thought it was a caterpillar. No one seemed to share her opinion. Janet said, "The likeliest thing was an earwig," but then it was too early in the season for those little, lazy, comfort-loving pests to have become troublesome, and in all our search we never met with one. I said, "Might it not be a snail or slug?" "Oh, no!" said Kate, very wisely, "it cannot be that, for the little molluscs never make those clear ring-like holes, they are much too greedy, they eat on straight before them until leaf, or flower, or whatever they have attacked is done with, unless they meet a midrib or dry stem which proves harder than they like. Besides, they would have gone to the Ferns at our feet in preference to making a long uphill journey for very doubtful food." Cousin Walter said, "It might be the crickets," with which our vinery was already sadly infested. "That cannot be," said Janet, "for crickets are anti-vegetarians."

So the search went on day after day, and the wonder whatever it could be agitated the two households in no small degree. Even Aunt Margaret shared in the search, and came in conqueror after Kate and I had spent a weary time, and Cousin Herbert pounds of paraffin composites, for the evening was his only spare time, and he would not use our farthing rushlights. Yes, Aunt Margaret came in one day with a little cinnamon-brown beetle stuck at the point of her darning-needle, looking hard at it as if afraid it would escape. "Is this the gentleman you are seeking?" said Aunt Margaret. "A clever fellow he is to hide away just on the very bit of Vine bark nearest to his own colour. I tell you what, Kate, with all your cleverness and your quick eye for shade and colour, you could not match yourself like this."

"Clever do you call it, Aunt Margaret?" said Kate, "I call it the Divine instinct of self-preservation."

"Well! well!" said Aunt Margaret.

"It is all chance," said Janet, "you might just as well have found it anywhere else—across the way on Maud's Dendrobium nobile, for instance." Janet's book-learning and French reading had made her rather sceptical about what she called simple things.

"I do not think it looks like an insect to eat Vine leaves," said mamma, who was at Ridge Close at the time, and who is a great lover of those little hard-backed fellows.

"Then, pray," said Cousin Herbert, "what was he doing up there? In truth, I searched the leaves under and over, but never once thought of the canes. You deserve a gold medal for your success, Aunt Margaret."

Then the poor little beetle was put under the magnifier and subjected to close observation. If he had any shyness about him he must have been greatly troubled. Some one wanted to keep it as a specimen for future use, but Aunt Margaret coolly put it in the fire, saying she was a member of the "Humane Society, and, doubtless, it was suffering from the prick of her needle." After this we found several; they were always hiding away on the bark, on the shady side of the cane. Whenever a new hole was seen then fresh search was made until they were fairly exterminated.

Through all the long summer days, and the shortening ones of autumn, the Vines grew and flourished. How much we thought of them! How proud we were of them! If they had been chickens, or children, they would have been spoiled right out with over-kindness or over-praise. Everybody admired them. They shot right out straight as an arrow, as if aiming to reach at one-year's spell the light graceful roof. Uncle Tetley used to go round the vinery nearly every day, and slacken the strings which tied up the Vines to some little brass hooks Cousin Herbert had put in by the sides of the windows for that purpose, saying as he did so, "The poor things must have room to grow." I have a fancy Cousin Herbert used to tighten them many a time to keep them up in their proper place. However, the canes did thicken fast, almost past belief.

Far into November the leaves were fresh and green, growing on still. Cousin Herbert became uneasy, "It could not be right," he said, "they ought to be going to rest as all the Vines in the houses about were. Papa sent George in to look at them and hear what he thought; but George came back a Job's comforter. "Ah, well!" he said, "they have grown much too fast. Such soft, hollow, fuzzy canes will never ripen to bear fruit, whatever Mr. Herbert may say, or his fine gentleman gardener. I know better than that, a bit of practice is worth a deal of theory."

Soon after this some frosty nights came and the leaves changed rapidly. Bright golden leaves they were, speckled over with brown, and they tumbled down in all directions, dust-dry withered things. Then, in December, Cousin Herbert bought a new knife to cut back the canes. It was quite an affair; we formed a procession to the vinery to see the operation. "They are easy enough to cut," said Cousin Herbert, when high up the ladder, "did not need a new knife for the operation." I begin to think, After all George is right, they are a bit soft and fuzzy.

"They are no such thing," said papa, who always sticks up for the Vines against everything and everybody. "Why, look here, at these good thick buds, I should not wonder but you may have fruit next year."

"Yes, if our Vine doctor will let us," said Kate, "but he says they ought not in justice to the plants."

"I would take no notice about what he says," said papa.

"To be sure not," said Cousin Walter, "take the gifts the gods send, and not wait for the years that may never be."

"I rather think your Vine doctor, as you call him, will have his own way, in spite of all you can do or say," said Aunt Margaret, "and I would not injure my Vines for the sake of one year's waiting. Some of us may live to see the fruiting years if Walter do not."

Cousin Herbert had a sorry time of it up the ladder, one wanting them to be cut shorter, another to be left longer; but in and out among the canes his knife went, and the work was soon done.

So the Vines were once more at rest; the canes were thicker and darker, the little brown beetle would have to get himself a darker coat if he wished to escape observation as easily as before; and the buds were large and plump and full of promise. Throughout the month of February we could see the sign of coming growth, the hidden life ready to burst forth when the spring sunshine called it. March they were out in full leaf, growing vigorously—nay, madly growing, as the Willow grows by the waterside, as if all life meant so much cane and leaf, and nothing more. Such monster leaves George could not find on our South Field Vines. He said he "was glad he could not, for coarse leaves would lead to coarse fruit."

In this second year we did not forget the syringing process, and tried our best to keep the house at a proper and increasing temperature. Several bunches of incipient bloom made their appearance to our infinite delight, but as the weeks passed the bloom did not open, but twirled and twisted itself up into tendrils. We pulled it down, even made little cotton bags and put in stones and bits of bricks and hung them up to the bunches to keep them straight, but they still twirled and twisted and would have their own way.

"Why, there would have been blossom, Miss," said George, only Mr. Herbert has washed it all away. Vines should never be wet after they come into leaf."

One day the Vine doctor, as we call him, came in. "I have been into your house," he said, "and looked round. Your Vines are in first-rate condition. I have cut them back properly and stopped the laterals. They will go on now famously. It should have been done before, but I could not get over sooner."

"I suppose they are bleeding, then," said Kate.

"Well, perhaps you had better take in some basins, or dishes, or something; it is a pity anything should be wasted; and yet it will do them no harm, they are in such rude health they can bear a trifle with impunity. I would cease syringing for the present if I were you, they grow fast enough."

When we went into the vinery and found the floor and shelves covered with leaves, and shoots, and laterals, we gave a great cry of horror. We thought surely ruin had come and no mistake, and asked in dismay, "Where would be the roots which all these leaves would have made?"

"Never you mind the philosophy of the roots; but look here, these are the leaves to take care of, for they feed the buds for next year's bloom; they must not be injured or broken off by any means. If you want Vine leaves, take some of those high up belonging to the eyes that will be cut away. It is better, though, to let them alone. Next year you will have fruit, I hope."

Although we told all this to Uncle Tetley, he laughed and would not believe, and a few days after a lady came begging Vine leaves to put about her French Grapes, a sort of make-believe they were English. What does Uncle Tetley do but invite her in to choose. So she, of course, all unknowing, chooses the lowest down, easiest to get, and the largest. Poor Kate declared boldly he must not take those, but one, two, were already gone. By main force—half play, half earnest—we held him back, Janet scolding all the time, asking what right we had to interfere to prevent her father from breaking off any leaves he might fancy—all of them, if it would give him pleasure. He was surely worth more than all the Vines in the world. "If I were you, papa, I would take what I wanted, they are all your own."

"They are not," I said sharply, "they are our Vines, and Uncle Tetley never calls them his."

Uncle only laughed, and the visitor declared she would much rather have a few small leaves if they could be reached. Though she said so, I am afraid she went away with her handful of leaves which our young Vines could ill spare, thinking us shabby, niggardly creatures.

So on into the summer months we went all prosperous, and yet we were not quite safe through the wood; for during August several of the leaves on two of the Black Hamburghs assumed a strange appearance, the edges of the leaves curling in as if to hide the stems; and the leaves when broken off and examined were scabbed and blistered, as if the green liquid which fills the little cells had flooded over, and in some evil hour broken up the light tissue boundaries. What could it be? what had caused it? were questions asked continually. We turned to the gardening books which had been pored over beforetimes without number, and soon found a name for the disease, its cause and prevention. But, oh! those warted leaves, how beautiful they were when seen through a magnifier! What a marvellous world each seemed to hold in its hollow! What glorious mountains covered with green moss and scarlet Lichens, the very stones among which seemed to sparkle like diamonds! and then such soft deep-sheltered vallies as to live in would be Paradise. Where the scabbed edge had been broken there seemed to rise up immense rocks, pile upon pile, and beyond these stretched long weary green plains, over which a feeble spider moved, like one of those huge, clumsy, extinct animals of the era before man was.

"Never mind fretting about it, Herbert," said Aunt Margaret one day, "it's my opinion Vines are like little children; there are so many diseases they are liable to, which they must have if they are ever to grow up. It's only their measles or chicken-pox period; they will be all the better when they get through it."

"Then after all we may sit under our own Vine and Fig tree, and hope to eat the fruit of our own growing," said Cousin Herbert one evening in autumn, as we lingered in the vinery. The rich sunset was tinging the dark leaves of an old Sycamore tree, and a silver-barked Birch was swaying to and fro, making long graceful shadows on the grass beneath.

"I wonder," said Kate, "if we should ever grow rich and great, and be forced to keep gardeners, if we should have as much enjoyment in proportion as we have in this little place."

"No, indeed, you would not; you are too independent, and like your own way too much, Kate, and you know too much. No, you would feel very like renting your own property, or living by sufferance in the house you had mortgaged," said Cousin Herbert.

"I think there would be a great deal more pleasure and comfort, certainly less labour," said Janet.

"I think there would be less idle time," said Aunt Margaret. "Ah, girls! you waste a great deal of precious time. When I was young, people never sat as you do, with folded hands doing nothing; they even took out their work with them when they went visiting."

"Then, I think, dear Aunt, we must be living in the reaction period," I said, "and yet all rest, all folding of the hands is not idleness."

"Perhaps," said Kate, "we work harder when we do work, and so get through more. At any rate, they say life's pulses beat faster than of old."

"Then why do you work so hard," said Janet, "and at a man's work, too?"

"Because I like it," said Kate, "and certainly it is not more

a man's work than a woman's. I think, indeed, it is the world's great plot of neutral ground belonging to all who have skill, or taste, or strength, to work in it, and all may work in it on a level, for the necessary outlay is small, it needs no costly tools. I often wonder dear Bessie Parkes never tried it as a good, a pleasant, and a remunerative employment. To be sure the Latin names might be hard to learn; but then many women have learnt harder things."

"And very fine they would look out in the rain and puddle planting monster trees they could not carry," said Janet.

"Well, I suppose few women live beyond the reach of a man's stronger arm, and help could always be procured to do what women were unable or unwilling to perform for themselves," said Kate.

So the autumn and the winter came again, the leaves all fell from the Vines; they were once more at rest. All rubbish was carried away, the house was smoked, well swept down, and our fire-maiden came in with hot water, soap, and brush, to "clean out the place," as she called it. How she laughed and sang at her work, called it her holiday, and how clean and fresh she made it, and the only extra cost to us was a new print dress for the one cook said she "had spoiled doing new-fangled work."—Maud.

(To be continued.)

THE GLADIOLUS IN POOR SOIL.

Being a great admirer of that beautiful flower the Gladiolus, I beg to state, in support of the opinion of some growers, that this flower does exceedingly well with me in very poor soil, very little better than brick-rubbish, and the atmosphere is not very good, the place being only one mile from London Bridge. I mention these facts for the encouragement of those who may think soil and situation may not suit this flower.

I have had spikes equal to those I saw this season at the Crystal Palace; they have been admired by experienced gardeners.—William Edwards, *Bermondsey*.

A VISIT TO TOWERVILLE, HELENSBURGH.

At this season (October), when the shadow of approaching winter is beginning to fall on the parterres and flower-borders, the lover of floral beauty can still find under glass much of the brilliance of summer, and even some of the first freshness of spring. On the afternoon of the 16th was gathered and arranged what it was feared would be the last bouquet of out-door flowers for the season. It was for an invalid lady friend in London, who would appreciate the gift all the more that it came from her natal district. It seemed to be the finest of the many which had been gathered and arranged in the course of the season. Next morning the hoar frost lay thick on plant, and flower, and grass, and at a glance it was evident that, in as far as the more tender specimens were concerned, my worst fears had been realised. Cast down though for the moment I unquestionably was, the thought that I was that day to pay a long-promised visit to a very dear friend, one of the most enthusiastic and successful amateur horticulturists of my acquaintance, dispelled the rising gloom, and made me forget the grudge I owed John Frost for coming on so very soon.

The day was not far advanced when I started. Glasgow was soon reached, and then by rail to Helensburgh—one of the most sunshiny seaside towns in the west of Scotland. The sun was bright overhead, but a misty veil hung over the Frith of Clyde, and shut out from view one of the most glorious panoramas on which the eye can rest, and which, if equalled, is certainly not surpassed. Arrived at our terminus, I hurried on to Towerville, along pleasant streets, skirted on either hand with villas and villa gardens, and, after a ten-minutes walk, arrived at the private entrance.

The first object that attracted attention was the flag which my hospitable friend had raised in expectation of my arrival, and which the morning breeze flung out from its folds with a force that made the strong flagstaff bend like a Willow sapling. Next the villa came in view, enlarged since my last visit; but so skilfully had the architect adapted the addition to the original building, that even a practised eye would fail to detect what recollection alone informed me of—that its parts had been planned and erected at different times. As it now stands it is, both internally and externally, a very model of its kind, and, while neither imposing from its size nor pretentious in its style, it gives one that idea of elegance and comfort which we deem essential to a seaside summer residence.

Another turn in the road brings the owner in view. He is leaning on a gentleman's arm, for, unfortunately, Mr. Henderson has been for the last eight months an invalid, set aside from any active share in the business of the important and influential firm of which he is a partner; but here his love of flowers and plants has served him in good stead, occupying without fatiguing his mind, affording healthful recreation, giving a present enjoyment, and leading heart and mind "from Nature up to Nature's God." As a man of business, as an enlightened patriot, as a warm-hearted friend, he has gained a name both in this country and in Italy, where he is even better known; and if it be the will of Providence that "a youth of labour" should be followed by an "age of ease," amid such scenes as those by which he is surrounded, I am persuaded that, even as he has no occasion, so he will not be found to complain.

The first cordial welcome over, and a slight repast disposed of, we are once more on the gravel on our way to see the latest novelties and improvements.

The lawn, with its adjoining terraces, stretches away eastwards from the villa. It is sufficiently extensive to admit of the introduction, without confusion, of a large number of our rarer Conifers and evergreens. All along the main approach, on the right hand there is a row of Cedrus deodara, while on the left hand these are admirably balanced with large Portugal Laurels, in the intervals between which rise deciduous trees in great variety, and a fine effect is thus produced. Among others were fine specimens of Wellingtonia gigantea, Cupressus macrocarpa, and C. Lawsoniana. One feature in the decoration of the lawn is quite unique in this part, but is easily accounted for by Mr. Henderson's long residence in Italy. Here and there, partially hidden by the evergreens, or skirting the line of walk, or forming the terminating point in some pleasing vista, are beautiful marble statues, copies of well-known works, and although, assuredly, we have not the warm, dry climate which some regard as essential to this kind of ornamentation, still the effect on the day of my visit was charming; and after the eye became accustomed to their presence I would not on any account have dispensed with them.

The great attractions of Towerville, however, are under glass. Adjoining the house is a small conservatory, in which a matchless collection of tree Ferns have their temporary abode. The larger number are specimens (some of them 10 and 12 feet high), of Cyathea dealbata, the fronds of which are already 5 feet long, and yet only one-half of their original size when they were dug up in their native habitat. The tallies attached to these splendid plants tell a marvellous tale. They inform us that in the beginning of this year (1866), they were growing in the depths of a New Zealand primæval forest; and now, after the lapse of only eight or nine months, they are throwing out their graceful fronds in every direction, overarching the on-looker with their silver tracery. What care must have been bestowed on them in their transit from the Antipodes! and what skilful treatment by Mr. Henderson and his clever painstaking gardener before a result so satisfactory could have been realised! A new house is being planned by Mr. Clark, of the Glasgow Botanic Gardens, for the reception of this interesting collection of valuable plants.

A few steps from the small conservatory is the Orchid-house—a spacious building, with a passage all round, so wide that it is obvious that the comfort of the ladies of the household has in this been consulted. The impression produced on entering this house is one not likely to be soon effaced. In front you have a tiny sheet of water, on which the huge leaves of the Victoria regia are floating as healthily as if on the surface of a Guiana lagoon, and in which some gold fish are glancing like flashes of fire. Overlooking the little lake, as if the *genius loci*, is a statue—a beautifully executed copy of the famous Nina del' Arno, surrounded on all sides by foliage of the richest colours and the rarest forms. Overhead a Banana (Musa Cavendishii), showing unmistakeable signs of fruit, shoots upward to the lofty roof its broad leaves, some gradually unrolling. The effect of the central row of plants, including another Banana (Musa textilis), is very fine, and is greatly heightened by the splendid specimens in front, by which their stems are concealed. Among these may be particularly noticed Cissus discolor (7 feet high), Maranta zebrina (4 feet high and 7 feet in diameter), Alocasia zebrina, and Alocasia metallica. Interspersed are large plants of Golden and Silver Ferns, such as are seldom seen elsewhere, and at least

one magnificent specimen of Adiantum cuneatum, for which I confess a special fondness. Between the pathway and the sides of the house a bench runs all round covered with plants, and over them, depending from the roof in wire baskets and on wooden matrices, you have Orchids in endless variety; the odd shape of the flower in one case, the rich colours in another, and the powerful perfume in a third, compelling you to pause and admire. Not a foot of space in this large house is lost, and yet the arrangement is so perfect, that when at the farther end you meet with a lovely copy of the Venus de Medici, you are satisfied that her presence there is in thorough keeping with the whole.

Attached to the larger building is a smaller one, in which the temperature is lower, and where another class of Ferns and Orchids is under cultivation. Here you may rest on the sofa and admire the wall over against you, clad with Moss and covered with graceful Ferns, which are retained in their position by ornamental wirework; on turning your eye to the right you may see reflected in the large mirror which forms the outlet the whole passage along which you have come, with its verdant and variegated fringework—

> "So wondrous fair, the whole might seem
> The scenery of a fairy dream."

Space will not permit me to speak of the greenhouse, or vinery and Peach-house, in the former of which are many rare and beautiful plants. My object is so far served, in showing what men of means and taste may do to provide an endless source of instruction and enjoyment for themselves and their friends, and in paying a just tribute to one who has used with such industry and liberality the advantages and facilities which, as an extensive shipowner, he enjoys for introducing new plants and splendid specimens of known species to our land, in which the disadvantages of climate can be overcome by the aid of art.—J. R. A.

CURRANT CULTIVATION.

The Currant is one of our most useful hardy fruits,and may be grown to perfection as well in the gardens of peasants as in those of the wealthy. Under ordinary circumstances it will be ripe by the early part of July, and by careful protection from the depredations of birds the Red varieties may be had in use until the end of October.

Although I venture to offer a few cultural remarks on this useful fruit, I do not by any means wish it to be understood that I anticipate offering any new suggestion, or writing anything not well known to the majority of gentlemen's gardeners; but I write for the amateur.

Whatever mode of pruning the Red and White Currants may be adopted, they require to be regularly pruned every year. In rearing young trees various methods may be practised, but the easiest and most general is by cuttings.

In raising trees from cuttings the first object to be attained is a clear stem about 6 or 8 inches high, and free from suckers. The cuttings are procured from the growth of the previous year, and for them the strongest, straightest, and best-ripened shoots should be chosen. All the buds on the portion to be inserted in the ground should be carefully picked out, leaving three or four of the terminal ones, and reducing the cutting to about a foot in length by taking off the unripened points. By removing the buds, or eyes, the trees are prevented from throwing up suckers, which are injurious, besides being unsightly and troublesome to displace. The cuttings may be planted in a shady situation in rows about 18 inches apart, and about 9 or 10 inches asunder in the row. They will generally in the first season produce about three shoots each, all of which may be allowed to grow during the summer, in order to assist in the production of roots. If it is intended that the trees shall be grown in the open quarters in the usual bush form—open in the centre, then when the leaves have fallen in the autumn, two out of the three may be cut away, leaving the third, the most upright, for the future stem, and shortening it down to about three buds; the lowest bud below the cut must be about 8 inches above the ground. Three shoots will usually be produced in the following year, and in the autumn the trees will be ready for their final planting.

Any common garden soil will suit the Currant, and it will grow freely and bear abundantly either in an open or a shady situation; but to insure good fruit the ground should be well cultivated, and, previous to planting, be trenched to the depth of 2 feet. While they will grow in almost any soil, Currant trees delight in a strong loam, and will there produce best, but on a sandy soil the crop will come in rather earlier. The time of planting will be from the fall of the leaf to the beginning of March, but to insure success they should be planted in October.

When the trees are planted the roots should be nicely and carefully spread out in a horizontal position, and the shoots may be reduced one-third of their length, taking care to cut to a bud pointing outwards. We have now a tree with a stem 8 inches high, and three branches diverging from it. Several shoots will be produced in the following season; but two should be encouraged on each branch, the rest being shortened to within one or two buds, or an inch of their base. The six shoots left will form the framework of the future tree, and should be again shortened to two-thirds of their length, or about 9 inches. On these other branches may be encouraged from near their base, and at a regular distance from each other of 6 or 8 inches at their extremities, and confining the head to the height of 4½ or 5 feet. When the trees are thus formed, by allowing the requisite number of branches to rise at regular distances from each other, they will require every winter the laterals or side branches produced in the previous year to be cut back to one or two eyes, around which a number of little fruit-spurs will be formed; and the leaders having attained the desired height must be cut to within two or three buds of their base.

There are some people who recommend summer pruning for bush Currant trees. Where trees are strong and luxuriant, producing a mass of watery spray, crowding the centre of the bush, this may be removed in June to admit sun and air—agents essential for perfecting the growth and flavour of the fruit. All the root-suckers may be twisted off. I may here observe that if there be no more shoots retained than will be necessary to remain at the winter pruning, the next season the tree will in consequence be less vigorous, for more leaves are encouraged, or more of the respiratory organs of the plant; and in proportion to these so will the roots be, and the more roots the more vigorous the tree.

Besides being planted in the open borders, Currant trees may be trained against a wall. For this purpose they may be planted 3 or 4 feet apart. In training wall trees two branches should be taken, right and left, in a horizontal direction, about 6 or 8 inches from the bottom of the wall. From these, upright shoots should rise at about 8 inches from each other. As these grow upwards the leaders will require shortening, according to their strength, to encourage the formation of fruit-spurs. The laterals must be shortened-in in June, and at the winter pruning should be cut nearly close to the old wood. Many other modes of training may be adopted, according to the inclination of the cultivator; but the same system of pruning may be invariably pursued—namely, spurring-in the laterals and shortening the leading shoots.

My remarks have hitherto been applicable to the Red and White Currants; the system of pruning to be followed with the Black Currant must be somewhat different. The Red and White Currants bear the fruit both on the young wood of one, two, or three years' growth, and on the older branches, from small snags and spurs on the sides of these, and which often continue fruitful for several years. The Black Currant bears chiefly on the wood of the preceding year; also from spurs, which, however, are less abundant and smaller in size than on the Red and White Currants. In pruning very little shortening is required. The chief thing to be done is, when the branches are too crowded, to thin them out, or to shorten back any that are becoming too high. No two shoots should be allowed to touch each other, and all cross branches must be cut clean away. The fruit is disliked by some people, and never brought on the table for dessert. It is used in tarts and puddings, and made into jellies, wines, and preserves.—Quintin Read, *Port Hill Gardens.*

GRAPES IN A COOL HOUSE FOR MARKET.

After many years of plodding industry my friend has accomplished his purpose. By the labour of his hands he has built himself a home. His plot of garden he has walled round, and in the enclosure he is about completing a vinery. His aim has been to obtain abundance of light and ventilation. He has succeeded admirably. The house is a lean-to, the back wall 18 feet high, length of rafter 18 feet, length of house upwards of 80 feet. He purposes planting twenty-seven Vines of a sort or sorts which will produce by sale the best returns.

On this point he asks my advice, and so anxious am I that he shall be advised in the best possible manner, that undeterred by any false pride as a gardener, I appeal to you, and should be greatly obliged if in an early impression you would name the kinds you consider most suitable; and what would you advise to be planted on the back wall? It is not intended to use much fire heat, but an apparatus is fixed in case it is required.—Yorkshireman.

[In such a house we would plant only Black Hamburghs. They are good croppers, and find a ready market. With the Vines at something like 3 feet apart, it would be useless planting much against the back wall. If the house is wide, perhaps it would be as well to plant Vines there, but they could not be expected to bear much until they reached the roof, after the front Vines were established.]

PEAR CULTURE.

(*Continued from Vol. XI., page* 461.)

2nd.—WALLS AND ESPALIERS.

Pear trees trained on walls with a few exceptions produce the finest, largest, and best-flavoured fruit. To have some kinds in perfection it is necessary to grow them against a wall, especially in cold, wet, exposed situations.

Selections of the best varieties for wall culture according to my experience and taste are—

THIRTY-SIX.

Doyenné d'Eté	Williams's Bon Chrêtien	Glou Morçeau
Jargonelle	Louise Bonne of Jersey	Forelle
Beurré d'Amanlis	Hacon's Incomparable	Jean de Witte
Gansel's Bergamot	Althorp Crasanne	Winter Nelis
Brown Beurre	Beurré Diel	Knight's Monarch
Thompson's	Joséphine de Malines	Napoleon
Seckle	Passe Colmar	Beurré d'Aremberg
Suffolk Thorn	Comte de Lamy	Beurré de Rance
Urbaniste	Van Mons Leon Leclerc	Ne Plus Meuris
Flemish Beauty	Beurré Bosc	Chaumontel
Figue de Naples	Duchesse d'Angoulême	Easter Beurré
Marie Louise	Bergamotte d'Esperen	St. Germain

Kitchen.—Uvedale's St. Germain.

TWENTY-FOUR.

Althorp Crasanne		

Those marked with an asterisk require a wall in cold, wet, exposed situations.

A wall for the cultivation of Pears ought to be 12 feet high, and not less than 10 feet. If under 9 feet high there is little chance of a crop unless root-pruning be frequently practised.

I have come to the conclusion, 1st, That if trees are wanted to occupy but a small space they must be on the Quince; and to have them fruitful root-pruning, or rather lifting, should be commenced with the planting of the tree, and continued biennially or triennially until the energy of the wood growth of the tree be subdued. 2nd, That to have the Pear on the Pear stock fruitful and healthy, space must be afforded sufficient to allow the tree to develope itself in its full proportions. 3rd, That root-pruning and frequently pruning, pinching, and stopping, though they favour fruitfulness, cause premature death.

From the above it will be seen that I am an advocate for plenty of room. I find Pears like it. They are fruitful or barren in proportion. The distance apart which I would recommend for Pears on the Pear stock against a 12-feet wall is 30 feet; on one of 11 feet, 33 feet; and upon a 10-feet wall, 36 feet. However high the wall, I would not plant the trees less than 30 feet apart. I have a Marie Louise upon a 20-feet wall, covering a space of 36 feet by 20, or 720 superficial feet of wall, which is no more than sufficient, and yet very little pinching is required. The tree produces fruit much finer in size, colour, and flavour than those afforded by trees occupying much less space. It is the same with trees of Glou Morçeau, Forelle, and other varieties. For low walls, or those from 7 to 10 feet high, trees upon the Quince stock are alone suitable; and they should be planted 12 feet apart on a nine-feet wall, 15 feet upon an eight-feet one, and 18 feet apart upon a seven-feet wall. If root-pruned 3 feet less distance should be allowed.

The above distances are for trees fan or horizontal-trained; but for upright training on the Pear stock, after which fashion trees are sometimes grown for covering high walls, I would allow 6 feet apart. Upright-trained Pear trees on the Quince may be 4 feet apart on a 12-feet, and 6 feet apart on a 10-feet wall.

For espaliers, when there are six side branches the trees may be 24 feet apart on the Pear stock, and 15 feet apart on the Quince, allowing 2 feet more distance between the trees for every less number of side branches.

It is to be understood that all the distances named are for trees planted in good Pear ground, for if the soil be poor the trees will not be nearly so vigorous, and they may be kept fruitful upon a less extent of wall. The same remarks apply where the soil is shallow and hot. In a poor light soil horizontal-trained trees may be planted 18 feet apart if trained on a 12-feet wall; and where the soil is of a medium texture 24 feet will be a suitable distance. For espaliers the distance may be lessened to the extent of 3 feet between each tree.

A west aspect is the best for Pears, and for the hardier kinds a north-west aspect answers tolerably well in the southern counties; but in the northern ones not only is a west wall necessary for the hardier varieties, but a wall with a south-west aspect is requisite in order to have certain Pears in perfection. In elevated and exposed situations nothing short of a west wall is suitable, and a south-west aspect would in many cases be preferable. It is worthy of note that the hotter the aspect the finer the fruit will be in respect to size and appearance, but these properties are very often no criterion of the real merits of a Pear. A Pear should not only have a smooth skin, be large and well-coloured, but be melting, juicy, and of fine flavour. These characteristics are not generally combined, for the fruit from trees on hot walls (not flued), are large and well-coloured, but are woody and juiceless, and have less flavour than those grown on bushes and pyramids. The fruit from the last, where the climate is suitable, is invariably the most melting, juicy, and high-flavoured.—G. Abbey.

(To be continued.)

WINTER PROTECTION FOR CELERY.

There are few places where Celery is not in great demand at almost all seasons, and much time and labour are required to produce first-rate crops of it. From the first handling of the tender seedling in early spring to the protecting time in autumn, considerable attention is required from the cultivator. It is not, however, my intention in the present short article to advance anything on a subject already so well known as the cultivation of this plant, but merely to put forward a plea for the better protection of a crop that may cost us some trouble, and it may be even anxiety, as I have known more than one employer fond of having large and fine Celery, who would be so dissatisfied in the event of its failure that the gardener was no longer secure in his situation.

After Celery has finished growing and been finally earthed up, it is in danger of decay, and no time should be lost in excluding from it heavy rains, or even slight frosts, either of which are the first death-blow to the heads. This is only found out when the digging-up takes place, when invariably out of every dozen one-third is found good for little. This is fre-

quently the case with the later part of the crop, more particularly in heavy, damp soils, and where the quantity grown being large it is impracticable to take it up and store it away.

The usual materials employed in the protection of Celery are fern, straw, or litter of any sort; but all of these are insufficient to resist such drenching rains as we have experienced during the past autumn. The natural growth of the plant is certainly above ground; the consequence is when it is treated artificially, by being buried root and stem, it is more liable to decay if not properly protected from an excess of wet.

The way we manage to save all our crop, let the weather be what it may, is as follows; the expense is rather considerable at first, but eventually a great saving is effected:—A quantity of old sailcloth was purchased at a sale, and it was cut into strips wide enough to form a kind of arch over the plants in the rows. A few stakes driven in between the plants along the row, with a strip of wood nailed over the top of the stakes, are sufficient to support the cloth. Pegs stuck in at each side of the ridge, a little below where the edge of the cloth reaches, and some strings attached to the cloth, will secure it from high winds. The cloth has a coating of tar, which enables it to resist the heaviest rain, as well as a severe frost, without in the least interfering with the foliage of the plants. After the rain or frost has passed away the covering can be taken off with little trouble.

If the above material is not to be had, old doors or sashes placed on each side of the ridge and the side edges brought to meet over the plants, will answer the purpose much better than the littering system. A free circulation of air around the foliage is necessary when the weather will permit. This is not obtained if the plants are almost covered with litter on the first appearance of frost, and the litter perhaps only removed as the Celery may be required.—W. C., *Boughton, Staplehurst.*

MATHIOLA BICORNIS.

We think you should call attention to this very acceptable addition to our annual flowers grown for their perfume. We can fully endorse all that Messrs. Backhouse said of it when they sent it out, which is saying a great deal now-a-days, when we see but few of the so-called "novelties" figuring a second year in flower-seed catalogues. Its only drawback is that the flowers are closed in the daytime; but we intend to try it mixed with Phlox Drummondi, Petunias, or some annuals of like growth this year, which will give the beds a pleasing appearance by day. Like most of its tribe it was vigorously attacked by slugs and snails, and doubtless in many places it never was seen after sowing.

The following is Messrs. Backhouses' description, slightly abbreviated, and we advise all who have not tried it to do so in the coming season:—

"An evening-scented Stock of unrivalled fragrance, from the mountains of Greece. No annual in cultivation, even including Mignonette, surpasses or perhaps equals this in the powerful and yet delicate perfume of its flowers. At 100 yards distance the scent of a bed of this annual, on a summer's evening, is often so strong as to arrest special attention. The plant grows 1 foot or more in height—the upper half or two-thirds being a branching spike of pink and lilac blossoms, partially closed during the daytime (when the scent is feeble), but expanding fully towards evening, and remaining so during the night and early morning. Unlike some 'night-scented' flowers, this is pleasing in colour, and, especially when grown in a mass, forms quite a pretty effect. The perfume resembles that of the Stock and Sweet-scented Clematis combined. It must be treated as a common hardy annual."

In reference to Mr. Robson's hint that we should give a few notes on the Apples suited for orchard culture, we beg to say that press of business at this season prevents us doing so; but we shall endeavour to give such a list some time this year.—Thomas Bunyard & Sons.

PORTRAITS OF PLANTS, FLOWERS, AND FRUITS.

Cattleya Dowiana (Captain Dow's Cattleya).—*Nat. ord.*, Orchidaceæ. *Linn.*, Gynandria Monandria. Native of Costa Rica. Flowers yellowish nankeen; lip crimson purple, with yellow lines. A superb species.—(*Bot. Mag.*, *t.* 5618.)

Bowiea volubilis (Twining Bowiea).—*Nat. ord.*, Liliaceæ *Linn.*, Hexandria Monogynia. Native of the Cape of Good Hope. Curious, but inconspicuous.—(*Ibid.*, *t.* 5619.)

Curcuma australasica (Australian Wild Turmeric).—*Nat. ord.*, Zingiberaceæ. *Linn.*, Monandria Monogynia. Introduced by Messrs. Veitch. Native of Cape York, Australia. Flowers yellow; upper bracts pink.—(*Ibid.*, *t.* 5620.)

Helianthemum ocymoides (Basil-like Rock-rose).—*Nat. ord.*, Cistaceæ. *Linn.*, Polyandria Monogynia.—Native of Spain and Portugal. Flowers yellow, with plum-coloured eye.—(*Ibid.*, *t.* 5621.)

Grias cauliflora (Anchovy Pear).—*Nat. ord.*, Myrtaceæ. *Linn.*, Monadelphia Polyandria. Native of West Indies.—(*Ibid.*, *t.* 5622.)

Pelargonium—*Meteor*, a tricoloured. Raised by Mr. Saltmarsh, Chelmsford. In the style of Mrs. Pollock.—(*Floral Mag.*, *pl.* 321.)

Aquilegia pyrenaica.—A dwarf species. Flowers purplish blue.—(*Ibid.*, *pl.* 322.)

Rose—*Napoleon III.* A Hybrid Perpetual, raised by M. Eugène Verdier. Dark crimson.—(*Ibid.*, *pl.* 323.)

Pansies—*Thomas Downie*, white, purple blotch and fringe. *Miss J. Kay*, yellow, crimson maroon blotch. *Imperial Blue*, blue, with deep purple blotch. *Hugh Adair*, white, dark mauve blotch. Raised by Mr. Fleming, Cliveden.—(*Ibid.*, *pl.* 324.)

Azalea—*Her Majesty* "is a sport from Madame Miellez, and one of the finest Azaleas which have yet been obtained, both as regards form and substance, while in colour and marking it is quite distinct from all others. The flowers are of the full average size, and the colour is a soft lilac-tinted blush more or less dense, white at the margin, thickly spotted with crimson in the upper part, and marked with variable stripes, or sometimes broadish bars of deep rosy purple. Its high quality as regards the flower itself, and this novelty of colouring, will make it an acquisition in any collection of these showy plants. Mr. Barnes says, 'I have never seen anything like a spurious flower upon it; and it is also a strong, robust grower'—two qualities which add immensely to its value."—(*Florist and Pomologist*, vi., 2.)

INTENSE COLD.

By our Meteorological Report it appears that the temperature near London fell in the past week to a lower point than has been recorded at any time during the last forty-one years. The minimum thermometer at Chiswick indicated on Saturday morning the 5th inst, that the lowest temperature during the previous twenty-four hours had been 11° below zero, or 43° below freezing. We are assured that the instrument was correct, and that its readings corresponded with other thermometers in the neighbourhood. It will be very interesting if our readers will communicate the temperatures registered in other parts of the country, and, as soon as it shall be apparent, the damage done to vegetation.

OKEFORD FITZPAINE.

A small, quiet, Dorsetshire village, nestling amidst the downs, and surrounded by orchards and pasture lands, where cider enough, and sour enough to give cholera to half the county, is made, and whence rich Dorset butter finds its way to the great all-devouring metropolis; with its church recently and well restored, without any of that gaudiness at which good taste must revolt; very like, I dare say, to many another village in its neighbourhood—such is the quiet haven where I believe we may say our good friend and ardent Rose-lover, Mr. Radclyffe, has anchored, or rather, let us say, is laid up in ordinary for the rest of his days. When one writes of Okeford Fitzpaine it is like writing about Stratford-on-Avon. It is the residence of our Rose-growing friend that will give it an interest in the eyes of the readers of The Journal of Horticulture, even as it is the "Swan of Avon" that makes Stratford the place of pilgrimage for many a true-hearted Englishman. Many a Rose-grower will find his, aye, and if not afraid of the bachelor Rose-grower, her way thither, and I know will ever find a hearty welcome. Let them drive up with a Maréchal Niel or Jules Margottin in their button-hole, and "open sesame" will be the word. Thither at the close of November I found myself wending my way; and albeit it was the wrong time of the year for Roses and Strawberries, I yet knew we should have a genial talk together, and that our imagination would clothe the Roses with their many-coloured blossoms, make us inhale the fragrance of the Strawberries, and even detect the bloom on the Peach trees.

At present any one, even a Rose-grower, might easily pass by Mr. Radclyffe's without noticing it, for it is one of those small, old-fashioned, cottage houses which we see in most villages, close to the road, with a strip of garden about 6 or 8 feet wide between the house and the road. I say at present, because yellow Roses are planted in front, and I doubt not will ere long cover it, as they did the house at Rushton, and so be sure to attract the passers-by. If the house is old the gardens are old too; but a master's hand has been at work on them, and I have no doubt that ere long they will be a garland of beauty and fragrance.

It is well known that Mr. Radclyffe is about the strongest client that Manetti has, that he has written it up on all occasions, and with justice too, for nothing could do better than his did at Rushton; hence all his Roses are dwarfs, budded low down on the Manetti, and the greater portion of them most vigorous. Here, for instance, as you look out of the window is a border of Bourbon Acidalie, consisting of six plants of that fine white, perhaps when caught well the finest white we have; there on that bank on the other side is a bed of Souvenir de la Malmaison. Then, as you mount the somewhat steep bank you find Roses on all sides—Roses in beds and borders, in sixes and dozens—here a dozen of Charles Lefebvre, there a dozen of Jules Margottin, another of Senateur Vaisse, and so on. Oh, what a crown of beauty these will be in July next! At the farther end of the garden you come to a long border of yellow Roses—Gloire de Dijon, Triomphe de Rennes, Celine Forestier, and such-like flowers, which will give a continuous bloom during the greater part of the year. You can see at once the liberal treatment they all receive—plenty of manure of good quality, dug in round the stems, and applied in every way. Then Mr. Radclyffe has an eye to the future. He has sunk a well and put up two pumps (no man could value water more than he does), so that he will be able to give them plenty of moisture if we have a dry season. There is only one point on which I have any doubt—viz., as to whether his Roses will do as well on the Manetti in this rich loamy soil as they did on the dry, strong, chalky soil of Rushton. There the stock throws vigour into plants which on the briar would have languished and died, but I am not so sure that he will find it the same on his present rich soil. I shall be curious to know whether the Manetti will not be too much for the Rose, and whether some of the not-over-vigorous-growing varieties will not succumb to its influence. I fancy I have found it so.

We of course had a long talk about varieties. Mr. Radclyffe has been so bitten by supposed novelties, that he has gone to the extreme, I think, of discrediting all new ones; but as soon as he finds that a variety is really good he sets to work at it, multiplies it, and obtains a good stock. Thus, in his 1200 Roses there might not be found, perhaps, so much variety as in some gardens, especially in those of persons who grow much for exhibition, but they are all well-proved sorts, which will not fail a grower when he wants a few dozens of good Roses. As his Roses had all been moved this year, their removal having commenced in August, there was not much autumnal bloom; but treated as they are, I am sure there will be abundance of it when they have the opportunity of returning the labour and care bestowed on them.

The Strawberries were looking in splendid condition, the collection comprising the best varieties in cultivation. Mr. Radclyffe has written so much on this delicious fruit, that I can only say that the appearance of his beds fully bore out the statements he has made concerning them. Rivers's Eliza, Dr. Hogg, Cockscomb, Mr. Radclyffe, Sir Joseph Paxton, and Frogmore Late Pine seemed to be his special favourites for growth and excellence. They were certainly most promising, and will by-and-by yield, I feel certain, if the season be at all favourable, a most abundant crop.

All who were interested in Rushton will remember the three wonderful Peach trees which were one of the sights of that garden, producing year after year large crops of fine fruit, and invariably succeeding in doing so when others had failed. Now these trees he could not remove, but he was determined not to be without Peaches; so one of the first things that he did was to run up a wall (which I think he will have to make higher), 217 feet in length; on this wall he has planted twenty-two Peach and Nectarine trees, which he is treating on the pinching and repinching system. He says the days of long pruning are or ought to be over. He is not, however, satisfied with these. He is trying the system known as the cordon or Du Breuil system, originated in France, and much practised there both for Peaches and Pears, especially in the neighbourhood of Montreuil, which supplies so much fruit to the Paris markets. He has obtained 107 trees of Peaches and Nectarines, comprising Noblesse, Royal George, Early Albert, Walburton Admirable, Prince of Wales, Barrington, Salway, Early Victoria, Early York, and Bellegarde Peaches; Pitmaston Orange, Victoria, Prince of Wales, Elruge, and Violette Hâtive Nectarines, all on the Plum stock. Of these he has planted fifty-five against the walls and fifty-two a little in advance. If these latter, he says, form fruit and do not ripen, he will another year put lights behind them; and he adds, "If I should succeed in raising fruit from the main stems of maiden trees that have never been cut down and trained, it will be probably the first time that it has ever been done."

It will be thus seen that for the lover of Roses or of fruits—for one who pursues his hobby with all a lover's ardour—there is abundance of interest at Okeford Fitzpaine. It is one of the glories of gardening that you have at all seasons something to interest. Your dried bulbs of Tulip or Gladiolus have each their history and are interesting; your bare bushes of Roses or well-covered plants of Strawberries are not dull to you; and what shall we then say of the glories of the garden in the summer, when the Queen of Flowers holds her court? Then will Okeford Fitzpaine be worth a pilgrimage, and I should gladly lay it out amongst my anticipations of the future, that I may be there to see, and rejoice with our genial and hearty friend in the success of his work.—D., *Deal*.

WORK FOR THE WEEK.

KITCHEN GARDEN.

Little out-door work can now be performed where snow has fallen, and we believe this is the case pretty generally; men should therefore be employed about such work as can be done within-doors, and which we have already pointed out. *Carrots*, where young ones are wanted early prepare a slight hotbed for the purpose, cover it with leaf mould to the depth of 6 or 8 inches, in which sow the seed. A little Radish seed may be scattered on the bed at the same time, but the Radishes must be drawn young. *Cucumbers*, the plants in houses must be strictly attended to, to keep them in health; refrain from removing or injuring any of the leaves, if possible; guard against over-watering, which is particularly injurious in dull weather; prepare dung for the main early bed; make a small seed-bed for raising the plants; after the heat is up, stir the dung inside the frame every other morning until the heat is sweet and regular. As soon as the young plants have perfected their seed-leaves they should be potted, two in a pot 4 inches in diameter, using some of the soil already in the frame. Plant them deep in the pot, so that a little fresh soil can be added as they grow. *Cauliflowers*, should the weather prove severe, the frames containing young plants should be covered with mats, or some material to protect them in some measure. Plants in the open ground should have some pliable rods bent over them, and then be covered with mats. *Dwarf Kidney Beans*, the plants in bearing should be placed in saucers or shallow troughs, having some soil in them, which should always be kept moist. This will encourage the growth of roots, and will also prevent the heat of the flue drying the soil at the bottom of the pots. *Lettuce*, when the frost is severe protect the frames which contain young plants for spring use. Those also which contain Cabbage Lettuce for present use must likewise be covered up. *Mushrooms*, beds should now be made in sheds or houses purposely fitted up for a spring supply. The horse-droppings should be well beaten down, and the bed should not be less than a foot in depth. Temperature sticks should then be thrust to the bottom in several places and examined daily; when the heat has become somewhat regular, and not exceeding 80°, the spawn may be inserted just below the surface, and the bed afterwards earthed up. *Sea-kale*, as that which was covered first is cut, remove the pots or boxes to that portion which has hitherto had no covering, so as to keep up a succession; the dung and leaves which have been previously used will serve the purpose again if a little fresh be added.

FLOWER GARDEN.

A change has taken place in the weather, which renders it necessary to protect all choice trees and shrubs in the open garden which are not hardy enough to withstand frost. The roots and the collar of the stem should be securely protected, as, if the rest of the plant is injured, there is some chance of its shooting again. Trees and shrubs that have recently been planted should have their roots secured from frost, and in some

cases it would be well to bind haybands round the stems of valuable trees. Cover choice bulbs sufficiently to prevent the frost injuring them, and also the roots of Fuchsias and other half-hardy plants. Roses must have additional coverings to the roots, such as litter, moss, leaves, sawdust, or rotten tan, and the tops must be protected with straw, fern, hay, laurel, spruce, or broom boughs, in fact, anything of that kind, and the drier the materials are used the better. The same remarks apply to creepers on walls. Over these mats may also be fastened, for although coverings are not required to be firm, the mats are useful in keeping the other materials dry and clean. Now is an opportune period to make and colour the plan of the flower garden, if not already done. Make it the *beau idéal* of what a flower garden might and should be, and so ascertain the quantity and quality of the plants requisite; then determine, in spite of difficulties, to carry the plan out, and a surprising amount of success is certain to follow.

FRUIT GARDEN.

Prune espalier Apples and Pears, and fork up ground about them in frosty weather, to disturb and destroy insects. In the orchard thin out cross and crowded branches from Apple, Pear, and Quince trees, it is a great mistake to have too much wood. Scrape off moss and lichen from the stems, and if time will serve, dress both these and espalier trees with a mixture of quicklime and blue clay mixed to the consistence of thick paint; if this is well done there will be no need to scrape them for some years.

GREENHOUSE AND CONSERVATORY.

Take advantage of bad weather to wash up and arrange the stock of dirty pots, to paint any tubs or baskets, wires, &c., out of use. Prepare labels of various sizes, and forked sticks for pegging down plants in the flower garden. Look over the stores, and provide whatever may be required for the season's use. The principal work in these houses will consist in keeping them and their inmates scrupulously clean. The conservatory should now be gay with Camellias and forced plants, which will take the place of the Chrysanthemums now over. Keep up a regular succession of plants to bloom in spring, by bringing forward the stock of forcing plants as wanted. Roses, both dwarf and standards, Honeysuckles, hybrid Rhododendrons, and Azaleas, with a host of other things, will enable you, in addition to the usual occupants of the houses, to make a brilliant show throughout the spring. Hyacinths, Narcissus, Tulips, Lily of the Valley, and other plants of the above class, must be duly forwarded as wanted. Hardwooded plants will require a dry, pure atmosphere to guard against mildew and damp. The surfacing of many plants that are not likely to require shifting can be performed. Great caution is required in the application of heat, as it would have an injurious tendency for the future to cause excitement at the present time amongst any tribes of plants that are required to bloom in their natural season. A day temperature of 55° will be quite sufficient here at present; if this cannot be maintained without strong fires, be content with 45°, and moderate fires, remembering that with this low temperature a very small circulation of the air will suffice. A high degree of heat would both hurry the beautiful Camellias and other choice flowers past their best, and create a necessity for the application of more atmospheric moisture, which, unless a warm roof is secured by covering, must end in drip, to the great prejudice of the delicate blossoms.

COLD FRAMES.

As long as the temperature here can be maintained from 32° to 35°, little harm will ensue by keeping them covered. Our practice is to tilt the back and front alternately whenever the glass rises to 32° out of doors. By these means the accumulating damp is dispelled, and the plants receive as much light as will prevent etiolation. Take care that the roof is well protected; the best way is to put a mat on the glass, then a coat of clean straw, and then another mat.—W. KEANE.

DOINGS OF THE LAST WEEK.

A FEW hints have come our way to the effect, "Beware of prophesying about the weather," merely because we mentioned frost as being likely to occur between Christmas and the new year. We never do assume to foretel what is to come, but our guesswork has not been so far wrong after all, as the new-year's morning brought a sharp frost with it, which would have been sharper still but for a fall of snow during the previous night.

Ice.—But for the snow on Wednesday morning, which covered the ice on our ponds somewhat deeply, and thus prevented the thickening of the ice, so as to give it strength for the ice-hook, we would have secured some on that day. We propose when the snow falls less heavily, and if the frost continue quite as severe as it is this (Wednesday) morning, to break holes in the ice and jet water over the snow-covering, which will thus by another morning give us a good thickness of ice, and enable the men to secure it from deep ponds without danger.

We cannot say that the last season has taught us any lessons about ice farther than have been communicated in former years, except this, that snow that had been collected, and with no great weight of ice above it, when dug out was not so firm as we used to have it, and though it answered quite as well for the butler's purposes as ice, it did not suit the housekeeper so well for pastry and icing. On the whole, we consider ice better than snow, when it can be had. Both do exceedingly well when mixed, and especially when there is enough of moisture, either naturally or communicated, to run all into a solid mass, not an interstice being left for air. Ice itself will keep better when so pounded together. All our previous experience with snow alone would point to the importance, not only of pounding it together well, but if the snow is at all dry, using a little water to make it go closer together. Last season we did not use much labour with it, as we expected to put in a heavy weight of ice over it, which would have done the compressing process for us. As it was deemed unadvisable to do so, the snow-ice came out less firm and compressed than usual. When snow is thoroughly compressed, there is little difference between it and ice. When not well pounded, it will be too loose for freezing-mixtures, creams, &c., though very good for cooling-purposes.

Sweeping Walks was a hopeless task. So long as the snow, though deep, was light, a broom could make a pathway quickly, but in half an hour there were 3 or 4 inches more snow. When the snow becomes deep, there is nothing better for walks and roads than simple snow-ploughs, such as a triangle formed of three stout pieces of wood 4 feet long, 1 foot deep, and from 1½ to 2 inches thick for walks, with a handle to hold by at the base, and a ring and chain in front for another man or two to pull by, according to the depth of the snow. For roads, the pieces of wood should be stronger and deeper, and if the base be 6 feet, the two sides should be 7 feet, and be well braced between to hold men or heavy weights if the snow is heavy. Such a simple machine, with handles like a plough, and one or more horses put to in front, would soon clear a great space of road. When the snow is deep, 5 feet in width at the base would be enough, and when once an opening is made, the space may be made wide enough by holding the plough sideways along each side of the opening, and thus sending the snow farther back each way. Except in deep cuttings, and large snow-wreaths, men can do but little with shovels in comparison with what can be quickly effected by such a simple plough.

Gutters and Leads of large houses should be examined, especially when frost precedes snow, as in that case, if a few leaves should collect in the cesspools for the water-pipes, the moisture contained about them may be frozen over hard, and if a sudden thaw come, and there is much snow on the roof, there will be no outlet for the water, the gutters and the leads will be flooded, and the water will pass through the roof and the ceilings of the rooms. We are apt to forget at times how much more quickly snow will disappear from a steep roof, even at an average temperature of from 35° to 40°, than ice will become melted that has been formed in the cesspool of a pipe. We have known cases where generally-intelligent people would not acknowledge this simple matter until they consented to put a pound of ice into a pound of water, even at 40°, and to wait until the ice melted. This simple experiment, too, and testing the temperature of the water in the melting process, would give an idea of the amount of caloric that was parted with before water could become ice, and the amount that must again become absorbed before the ice could be changed into water. At any rate, we can recollect of fully half a score of cases in which, owing to the slow melting of ice, and the unwillingness to incur the trouble and the expense of sending a man to the roof of the house to see if all the water-courses were clear, what would have been obviated by even less than a day's wages has involved a loss, in damage to ceilings, papering, and furniture, of scores of pounds, and in one or two cases hundreds would have been nearer the mark. This is a matter generally attended to by the carpenter, bricklayer, or gardener, and very often by the last. There is nothing very desirable in

the job; but it is important that some one should have it as a matter of duty to attend to, otherwise it may turn out that what is the business of everybody may become the business of nobody, until after much mischief is done. Perhaps, too, the appointing some one in particular to look after such a simple matter is all the more important, as just in proportion to the energy, fidelity, and industry a man brings to bear on his own particular department, so in general will it be found that he is extremely sensitive as to going at all out of that department without clear and specific orders and defined arrangements.

KITCHEN GARDEN.

Here the weather has pretty well brought all matters to a stand, and rabbits and hares will give us little trouble with some other things. We have before had trouble with young plantations of Cabbages, but now we shall have none with a nice quarter planted in September. Not a single plant is left, and Brussels Sprouts will ere long follow them if the four-footed game are to have their way. These Cabbages had been netted round, but nothing but high wire netting would have kept the vermin out. Seeing how matters were going, we have potted some hundreds of strong Cabbage plants, and set them in an orchard-house, resolving to plant them out in better times. We did so with a fine lot of Cauliflowers last season, and after all they were so cut off level with the ground by rats, that to have Cauliflowers moderately early we were obliged to force them on under glass lights. Wherever game and rabbits are encouraged close to and in the garden, rats follow as a matter of course, and they will increase do what you will, until they pretty well frighten people to go out at night from the strength of their bands, and their clearing everything that is eatable before them, as we have reason to believe, from the newspapers, they are already doing in some parts of the country. All forced vegetables are much the same as in previous weeks, and it is well to have a good stock in such weather, as it makes one more independent of out-door supply.

FRUIT GARDEN.

The weather did not permit of much being done out of doors, with the exception of wheeling to Gooseberries and Currants manure and the decomposed rubbish-heap, which will be pointed in when the weather changes. After the heavy snow on Wednesday morning we took the opportunity of *smoking* the orchard-houses *with bruised Laurel leaves*. The snow was shaken off the Laurels with a rake, and a dozen armfuls of the young shoots were obtained. The task was not one of the most pleasant, but then it did not last long, as the shoots and leaves could be beaten and broken inside, and then there was plenty of in-door work for the day. These houses are so open that it would be a great trouble to smoke them with anything, unless at such times as there was a good covering of snow on the roof. We need not give details as to making the small fires and piling the half-bushels of bruised Laurel shoots and leaves on them, farther than this, that the great object is to obtain all the smoke possible, to have it cool, and never to allow a twig or a leaf to flare. The houses were filled with a very dense smoke for at least six hours, and though we have no faith in any kind of smoke destroying the eggs of insects, we would not give much after such a continued smoking for anything having the breath of life. Even a man could scarcely go in to look at the smouldering heap for a few minutes. We forgot, we think, to answer the question put last year as to the efficacy of such smoking with Laurel leaves and shoots as contrasted with tobacco smoke if it could be cheaply obtained. Well, if equally cheap, we would by far prefer tobacco of home-growth or otherwise, and one of our correspondents lately showed how that could be successfully and economically grown in shrubberies in fresh soil, and afford there, too, a nice appearance; but at present, not to speak of the law interfering with private growth, there can be no comparison as respects expense between tobacco and the Laurel leaves for smoking for such purposes; and as prevention is better than cure, we would always be inclined to resort to the plan under similar circumstances. Through this and other precautions we have of late years been troubled with few insects, with hardly one all last season in these houses. We must not, however, make too sure, and a little effort to secure freedom from insects now will be much easier than killing them if they do appear at a critical time. With snow-covered glass and all together we could scent the pungent odour of the Laurels some hundreds of yards from the houses.

ORNAMENTAL DEPARTMENT.

The great object has been to keep cold pits and frames secure by covering, and in houses just to keep plants safe, and at the lowest temperature compatible with safety; and this required the smallest amount of air to be given, and also prevented the waste of heat in raising into vapour the amount of moisture that would have been required in a higher temperature. Until now, damp and excessive vapour in the atmosphere have had to be guarded against, and no great amount of vapour will have to be added to the atmosphere of houses kept in a cool state, say from 45° to 55°—at least not much more vapour will be required than can be given by damping the floors and stages of the house, unless the outside thermometer should be much more than 10° below the freezing point. Much also will depend on the state of the atmosphere, as a glass house will often be more cooled in a temperature of 5° below freezing, with a brisk wind, than it will be when the outside is 10° below freezing, but with not even a zephyr moving. In protecting we threw a little straw over some pits supplied with a little heat inside, but in all other cases we were glad of the heavy fall of snow. It will protect many vegetables from the cold, and it will make cold pits and frames more secure. As we know that the temperature inside is low enough, so as to arrest growth, we will not take away the snow or expose the glass so long as this weather is likely to last, and the keen frost along with the snow, even with a low barometer, would lead us to expect some days longer of it.

So long as this stormy weather lasts the keeping the houses safe, with no waste of fuel, must ever be a first consideration. If the damper is not used, heating by hot water must always be expensive, and for small single houses much more so than flues or stoves. We have been amused by the details given by "Maud" about lighting a stove, and could corroborate them with instances of those who ought to have known better. Looked at from "Maud's" stand-point, the whole article is admirable; looked at, as we think unnecessarily, by bringing in the gardener's stand-point, there are several allusions that may receive hereafter a little healthy criticism. But as to the fire, we have had many smart young men beaten with a furnace, that, besides heating a boiler, went through a long tortuous flue in the back wall of the house. When this furnace fire was lighted after long periods of damp weather, there was no chance of making it draw if a soot-door, near the end of the flue, was not taken out and a small brisk fire put in the flue there. We recollect seeing four clever fellows once, almost as black as chimney-sweeps, but with bright lines down their cheeks where the water was brought liberally from their eyes by the acrid, sour smoke. We had seen the smoke pouring out of the shed in which the stokehole was placed instead of coming out at the chimney-top, and had heard the men called in, one after another, to consult, as smoke-doctors, in the great emergency, as to how to make the smoke go up instead of out on them, and all without avail. Well, everything had been done correctly, a little dry litter and dry wood had been used for lighting, the furnace door had been shut, and the ashpit door had been opened that the air might reach the fire through the bars, and yet out poured the smoke by the crevices of the furnace door, open ashpit door and all—and why? because no one had thought of the damper, which was full in near the furnace, and when pulled out smoke and flame shot up like a sky-rocket. We congratulate "Maud" on having such close-fitting furnace and ashpit doors. They are the first essentials to economical heating by boilers; and the second essential is the due regulation of the damper—that is, the damper should be pulled out on lighting the fire, at least for half its length, and then whenever the fire becomes bright and the heat is well up, shove the damper in to its full length, and afterwards draw it out just a little to give a little draught. There seems to be so much difficulty in this simple matter, even among professionals, who, by having the damper out at all unseasonable times, send the heat from tons of coals up the chimney, that we have come to the conclusion, that in all heating of small and moderate-sized houses by boilers, it would simplify matters to pull the damper out partly when lighting the fire, and after the fire was established to send the damper at all times right across the flue, but to have a hole in the centre of the damper about 1 inch in diameter, or two or three holes that would come to as much, which would be sufficient for draught, and yet send much heat back again on the boiler.—R. F.

TRADE CATALOGUE RECEIVED.

William Paul, Waltham Cross, London, N.—*Select List of Vegetable, Flower, and Agricultural Seeds, Seed Potatoes, &c.*

COVENT GARDEN MARKET.—January 5.

The wintry weather of the past week has shut out the greater part of our supplies, as the growers are almost unable to get to market, and rough goods have considerably advanced in price. Oranges and Nuts are plentiful, owing to the large stocks on hand; but Pears are very limited in quantity, and good dessert Apples command a ready trade. Potatoes remain as before, but there are few arrivals this week, and very little business has been transacted.

TO CORRESPONDENTS.

*** We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed *solely* to *The Editors of the Journal of Horticulture, &c.*, 171, *Fleet Street, London, E.C.*

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

Beurré de Rance Pear (*J. J. T.*).—You were misinformed. There is only one Pear known by this name. It is fully described and its synonymes stated in Hogg's "Fruit Manual." We apologise for having omitted this answer accidentally for so long.

Nitrate of Soda for a Lawn (*Berley*).—Nitrate of soda is usually sold under the name of cubic petre. It should be pounded fine and sown over the lawn in March at the rate of 1 lb. to each thirty square yards.

Osier Planting (*Salix, Dublin*).—For white basketwork, the French Willow, Salix triandra; for other baskets and fine wickerwork, Salix Forbyana. The annual shoots of the first are not less than 8 feet long, and of the second not less than 6 feet. The sets should be planted 3 feet from each other. We do not know which species is locally known as "The Packthread Willow."

Books (*A Subscriber, Bandon*).—"The Garden Manual" for twenty postage stamps, "The Poultry Book for the Many" for eight postage stamps, and "Bee-keeping for the Many" for five postage stamps. If you enclose the stamps with your direction, the books will be sent to you from our office post free.

Garden Walks (*Idem*).—You may make most excellent walks without gravel, if you can procure gas tar and follow these directions:—A layer of stones, brickbats, shells, or clinkers, 6 inches deep, to form a dry bottom; a layer of chalk or lime, in the proportion of one to ten of the stones or other foundation, and well rolled and watered to the thickness of 3 inches, with a rise of 2 inches in the centre; over this half an inch of gravel and lime, or fine chalk; water and roll well again; add one-eighth of an inch of the best coloured gravel; and again roll until quite solid. Have the walk 2 inches wider on each side than you desire, as this checks the turf and weeds from encroaching, and prevents the rain water getting to the foundation of the walk.

Stocks for Camellias—Propagating Azaleas (*Constant Reader, J.H.*).—The best kind of stock is the single-flowering Camellia. The stocks are raised by sowing the seed, or from cuttings, but the latter are not nearly so free-growing. The beginning of April is a good time to graft Camellias. The varieties of Azalea indica are propagated by cuttings taken from the shoots of the current year when about half ripe; inserted in very sandy peat and silver sand under a bell-glass on a gentle heat, they root freely. The "Garden Manual" will suit you. It may be had free by post from our office by enclosing twenty-six postage stamps with your address.

Evergreen Trees for a Blind (*Ben*).—The Weymouth Pine we fear would not serve you; but Pinus austriaca and Scotch Fir would, we think, grow well when established. Pinus cembra will grow almost anywhere, and Pinus maritima thrives in such a soil as yours; so does the Pinaster Pine, of which Pinus Hamiltonii, about which you inquire, is but a variety.

Pteris serrulata Sowing (*M. H.*).—The spore-cases on the part of the frond sent us were ripe, and the spores shed. It will suffice to place the fronds over the pans full of compost, and to rub the under side of the frond with the hand gently, so as to cause the spores to fall on the surface of the compost. If you do this until the surface is covered with a fine brown powder perceptible to the eye, you have done all that is needed.

Camellia Leaves Yellow (*Idem*).—Your plant is only shedding its old leaves. Continue it in the stove until the growth be perfected, keeping it in the coolest, lightest, and most airy part. When the wood becomes firm, and the buds show in the axils of the leaves, remove the plant to a cool house.

Netting to Protect Seed-beds (*Tyro*).—You can obtain the netting of any dealer in fishing tackle, and such is frequently advertised in our columns. You may save yourself much trouble in the protection of seed-beds by moistening the seeds you propose sowing, throwing a few pinches of red lead over them, and mixing up so as to give the seeds a reddish hue, or a slight coating of the red lead. No birds take our seeds now, and we simply treat them in the above manner before sowing.

Mixing Animal Manure and Lime (*Idem*).—From the fact that lime sets free the ammonia by causing rapid decomposition of animal matter, it is considered wasteful, ammonia being produced faster than the plants are able to appropriate it, and it is consequently often lost. Animal matters had better decompose slowly, and thus give out ammonia gradually.

Trenching (*Idem*).—Your ground will be all the better of a good trenching, bringing some of the subsoil to the top, so that by exposure to frost and air it will be rendered suitable for the growth of plants. The black soil is best at bottom. The roots will go down to it.

Grafting Pelargoniums (*R. J.*).—Your best mode of grafting will be side-grafting, leaving the head of the stock partially reduced until the union is complete. The operation would be much facilitated by placing the plants worked in a gentle heat of 50° or 55°, and a bottom heat of from 65° to 70°, and maintaining a close and moist atmosphere, with shade from bright sun. The surest of all modes is grafting by approach, or inarching, and you may follow that mode by raising the plants for scions to the height required, they being in small pots.

Red Spider on Peach Trees (*H. H.*).—Unnail the trees, and wash the wall with a solution of 8 ozs. of soft soap to the gallon of boiling water. If the wall is very much cracked and full of crevices, have all the joints made good with hair mortar, and wash the wall with fresh lime and soot, mixed with sufficient urine to bring them to the consistency of limewash. Apply the mixture boiling, and take care not to drop the wash upon the trees. Before nailing wash them with a solution of 4 ozs. of soft soap to a gallon of water, and apply it at a temperature of 140°, taking care not to dislocate the fruit-buds. The best preventive of the attacks of red spider is to keep the trees well syringed with water from a garden engine during hot weather, and to afford them plenty of water at the roots. Avoid gas tar.

Cucumber (*L. A.*).—"Telegraph" is, as you say, one of the most prolific and best varieties for early forcing. Any of the principal London seedsmen, we should think, could supply you with seed of it.

Wood of Peach Tree (*X. A. B.*).—The wood enclosed by you was perfectly healthy. The darker colour of the centre is natural. As you do not state whether the tree was over-luxuriant, nor any other particulars, we cannot suggest the cause of unfruitfulness. Cutting off the branches most probably was wrong.

Drying Plants (*Hortus*).—Put them properly spread out on dry sand, and cover them with some of the same, and dry them in a gentle heat. When dry fasten them by stitches of thread on cartridge paper.

Greenhouse Constructing (*J. F. C.*).—We like, as a whole, the proposed plan of your house very well. We would advise that for a 14-feet-wide house, the back wall should be from 2 to 3 feet higher than the proposed 11 feet. The modes of ventilating will answer very well. The proposed conical stages in the house—that is, four shelves on the one side, four on the other, and one wider at top in the centre, will answer for storing away great numbers of small pots in winter. For showing off flowering plants in such a lean-to house, a flat-sparred table 24 or 27 inches off the ground would do as well and cost much less money. The proposed heating will keep out sharp frost. If you wanted more heat you could take two pipes, smaller ones, along the back and as far as the doorway. You could also greatly help by having a cistern where your two proposed pipes terminate at the doorway. The 16-oz. glass you allude to would do, and so would the rafters 20 inches apart, but to have a nice fixed roof, and be in little danger from hail, &c, we would advise the rafters to be 18 inches apart, and the glass to be 21-oz., though it would cost nearly a third more. Wood will answer for the front shelf, but stone or slate would be better. To do justice to the plants the Vines should not be nearer than 5, or even 6 feet to each other. Conical boilers supplied from the top are easiest fed, but unless the grating works on a pivot so as to let all fall down, they are worse to clean out. On the whole we think a small saddle boiler will be as useful to you; in fact, if the house had been ours, and the pathways had been tiled instead of being flagged, we would have had a small flue all round below the tiles instead of a boiler, and then on a cold day the warm tiles would be comfortable to the feet. We think your stokehole and all else will do.

Lifting Vines (*S. D. M.*).—The Vines you propose lifting will, if the operation be carefully performed, bear a crop next season, but we would not take more than half a crop, and if the Vines show weakly, we would not allow them to bear this season. After replanting cover the border over the roots with 18 inches or 2 feet of hot dung, keeping the house cool for a fortnight or three weeks, and allow the Vines to break naturally—that is, do not force them. The chalk will answer for the border instead of lime rubbish, but we prefer the latter.

Converting Pits into a House (*A Prolix Inquirer*).—Your range of brick pits 29 feet long by 5 in depth, we have no doubt would make a good house by going to the expense of adding to them another side and ends, thereby making a span. You do not state the width, and we cannot, therefore, advise you as to size and the purposes for which it might be employed. Unless you have other pits or frames we would not recommend the conversion of the former into houses; for,the expease is in many cases equal to that of new structures, and after it has been incurred the converted pits are seldom equal to such in durability, appearance, and utility. Besides, after much has been spent in the conversion of the pits, further outlay will probably be necessary in providing new frames or pits, which are for all intents and purposes the most useful of glass structures. If you do not want pits for Cucumbers and Melons, and for affording protection to plants, or if you elect to grow them in houses, when a place already built and needing no increased expenditure would answer as well, if not better, the proposed conversion may be made. The case will be different if the pits are of sufficient width for a house already, and only need pathways and slight alterations for heating, &c.; but even then we do not see how your garden will be complete without frames or pits, nor how you will manage without them.

Labour for a Garden of One Acre (*Idem*).—Your garden of one acre, one-fourth of which is grass, one-fourth shrubbery, and the remainder kitchen garden, with, in addition, a greenhouse and the pits above named, will be well managed by a gardener, affording him occasional help such as that you speak of by your groom, though it is as well to keep every servant's work as distinct as possible, and interfering as little with that of others as the case will permit. Doing so saves much grumbling, which is never pleasant to either employer or employed, and, besides, no master can teach a servant a more important lesson than that of self-reliance. It does away with all excuses, and every one is then able to answer for himself. An active and skilled gardener would manage your garden to your satisfaction, and he would have nothing to complain of in respect to being overwerked. We think a gardener of the qualifications you require, ought to have 25*s.* per week without a cottage, or 21*s.* per week with one. We think it is not only consistent with "your interest," but that of your gardener also, that "you should take an active interest in the garden," for where there is no interest the master will often neglect furnishing proper working plant and materials, which to an active servant is discouraging.

Culture of Water Lilies in a Vase (*Rus in Urbe*).—1, Plant them during April or May, securing the roots in the mud, and pressing it about them so that they may be kept at the bottom; or tie a moderately large stone to the root of each, which we find from experience to answer well, the plants being dropped into the vase at the desired place. 2, Place 6 inches of turfy loam of a clayey nature at the bottom of the vase, and equally over it, and a short time after the plants are put in cover the mud with an inch of fine gravel from which the dirt has been washed out. 3, The Lilies will thrive if fresh water be admitted every day to the amount of one-third the contents of the vase. By fresh water, rain or pond water is meant. 4, It would do to feed the vase with soft water by a pipe from a cistern at the top of the house; but as you say the supply from that source would only be available when rain falls, it may be too uncertain and insufficient. The vase should at all times be kept full of water, and never have less than 1 foot of water in it, and better the full depth of 18 inches. Gold fish would thrive in the vase very well in summer, but not in winter, for the water will be liable to be frozen in a mass during severe weather, and if not it may be too cold for the fish in winter. If the vase were placed in the ground so that one-third or so were above the ground, you might have the gold fish in winter as well as summer, covering half the vase over on the approach of frost with a thickness of 9 inches or 1 foot of straw, and removing it in spring. This would not interfere with the Lilies, and it would save the fish, the ice of the uncovered part being broken daily.

Hollies Grafting and Budding (*Ilex*).—The grafting may take place when the stocks exhibit signs of growth, or begin to swell their buds, which will be the case in April, the scions being taken from the trees and inserted in the stock the same day. Let the scion be the wood of the previous year, and of free growth. Budding should be performed when the leaves of the tree from which the buds are taken have attained their full size and the buds are discernible in their axils; it requires a certain amount of discrimination to make sure of wood-buds. These are more generally situated on the strong shoots, and especially those that come from a branch which has been cut back or shortened. Drawings and full directions for grafting and budding are given in "Fruit Gardening for the Many," which you can have free by post from our office, if you enclose five postage stamps with your direction.

Names of Fruits (*W. B. S.*).—No. 1, Beauty of Kent; 2, Margil.

METEOROLOGICAL OBSERVATIONS in the Suburbs of London for the Week ending January 5th.

Date.	Barometer.		Thermometer. Air.		Thermometer. Earth.		Wind.	Rain in inches.	General Remarks.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

GAME FOWLS.

SHAPE AND CARRIAGE OF TAILS, AND OTHER POINTS.

Adverting again to the article by "Yorkshire," of the 27th of November last, I am well aware that many breeders, exhibitors, and judges prefer the close-switch or whip-tailed birds, but fully as many, I think, prefer the noble, full, ample, spreading-tailed birds, or "the up-and-spread-tailed" birds as they are termed. I never did or could like the very close-tailed birds, or pinched-up, cramped, and shrunk tails, as I think they give the birds a meaner appearance, and the narrow tail makes the body appear too bulky, or clumsy; whereas the ample spreading tail makes the body appear smaller and neater in size and shape. The up-and-spread-tailed birds are shorter in body and in feather in general, as well as more spirited, I think.

The advocates of the switch or whip-tailed birds say that these birds have neater tails, and are generally closer in feather. I cannot see this, and think the ample tail is nobler and gives the bird a nobler appearance, and I also think that the full crescent-like curve of a well-sickled tail is one of its greatest beauties. The best hens should have their two upper-tail feathers with a slight and graceful curve, which adds to their beauty, I think. The whip or close-tailed birds would look as well, especially the hens, if they had only a few upper feathers in their tails, as they might almost as well be without half their tail feathers.

In my experience the least-spirited birds are those with the long, drooping, closed tails; and the most spirited have the rather short tails, carried well up, and spreading or fanned, with curved upper feathers. Game fowls' tails should not, however, be so high as Bantams' tails. Long-tailed Game fowls are certainly longer both in body and in feather than short-tailed birds are. If not for this defect, the long-tailed would possess the most beauty. I do not, of course, admire the coarse and clumsy tails found in birds that are coarse in feather and in bone. The happy medium is, I think, best as to the length of tail, nor should birds be too cocked-tailed for true beauty. Doctors differ, however, and so do amateurs of Game fowls on this point.

Breeders differ also as to the length of the legs and wings. I think the happy medium is also best here as well. A long-legged bird over-reaches his opponent in fighting, and moves his legs too slowly; and a too-short-legged bird must "fight very close" to reach his opponent at all. A too-long-winged bird is too long in body in general, though long wings are the handsomest. A too-short-winged bird is too heavy in the body in proportion to his wings for flight, and is ugly. Game cocks should never carry their wings upon their backs like Geese. They should carry the wing so as to protect the fleshy part of the thigh, but not so low as a Bantam's wing is.

Cocks of 6 lbs. weight are too heavy and too slow in their motions. Cock chickens as a rule seldom reach quite the weight of their sires; therefore, I think that brood cocks from 5¼ to 5½ lbs., or 5¾ lbs. at most, breed the best chickens for exhibition. Light-fleshed active birds are, of course, the best brood cocks. I have also noticed that the tail feathers in the spread or fanned-tailed birds stand stiffer, stronger, and harder than in the close-tailed sorts. I am convinced that a drooping tail shows a drooping spirit.

Remarks such as those by "Trent Side" and the old Scotch lady, of course, merit no reply whatever, and require none. Some admire clumsy beauty, and some the trne and symmetrical beauty. I am of the latter number. I can only deny that I have ever been "put right," or "put out" either,

by any remarks made, as some of the writers of them appear to have been.—Newmarket.

EXHIBITING BORROWED FOWLS.

You ask, Is it not contrary to all poultry exhibition rules to exhibit birds not the exhibitor's own? In reply, I say that scarcely is there a poultry show in this district (and I believe others to be the same), in which every pen of birds belongs to the person who exhibits them. I will take for example Middleton, Birmingham, and Manchester. I was at the whole three of the last Shows held at these places, and at two of them I know birds were exhibited that did not belong to the persons who had them in their names, for I knew the birds as well as I know any person I do business with.

Besides, it is, I assure you, quite common with the largest and most successful exhibitors to borrow and lend, particularly if their own birds get out of condition, &c. I could mention the names of a host of persons who would tell you they did it (if they spoke truly), and that it is a general understanding amongst friendly exhibitors to borrow and lend. Within the last few months I have known poultry travel for more than thirty miles, to be exhibited at local shows in the borrower's name; and generally it is understood, as I have said before, to borrow and lend, if agreeable, which is often the case, to the parties so dealing.

If this practice is brought up amongst the poultry world, a good many will say, What harm is there in it? If birds can beat mine on their merits, I am glad to see them do so, no matter under what name, nor who is their owner. Certainly if they are borrowed birds there is no honour for the exhibitor, and no one knows that any better than the party who wins under such circumstances. In this district secretaries and committees, as my countrymen say, "wink" or close their eyes to the borrowing and lending system, and I think some schedules do not specify that the birds shall be the exhibitor's own, and this has been done because the exhibitors were the masters.—Exhibitor.

[The foregoing is from an honourable exhibitor, who would not adopt a practice that is contrary to good faith. In his own case he exhibited in the name of his breeder, which needs no objection; but we consider that borrowing fowls to exhibit is open to great abuse, and, therefore, should not be allowed.

Let us take as an instance a poultry-fancier, whom we will call G, having a yard of ordinary Cochin-China fowls, and hiring from a well-known breeder of that variety, whom we will call H, a pen of his best birds. G exhibits and gains a prize, and, consequently, is enabled to sell eggs and chickens at a high price. Is not that obtaining money under false pretences?—Eds.]

INJURIES OCCURRING TO EXHIBITED BIRDS.

I exhibited a Golden-pencilled cockerel at Manchester. He was delivered to the railway company in perfect feather, and on my arriving at the Show on the first day (Dec. 21), at 10.30, I found both his sickle feathers had been drawn. The Secretary of the Show knew nothing of the matter, neither were the feathers in the basket. Who is responsible?—Charles Sidgwick, *Ryddlesden Hall, Keighley*.

[The difficulties in such cases are the proving the amount of damage, and who was the wrong-doer. If a railway porter caused the damage the railway company would be responsible; if a man employed by the Exhibition Committee, that Committee would be liable.—Eds.]

LEEDS POULTRY SHOW.

In the report of the above Show, page 493, is the following remark:—"The next class was for Black Bantams, and they were good—so good that Birmingham first-prize birds could not gain the Judges' notice." How your correspondent can so far have fallen into mistake is to me an enigma, unless his words are intended more in irony, as it was patent to all eyes that one of the greatest possible mistakes had here been made, if we may rely at all upon the rule laid down by our greatest authorities, that "Black Bantams shall have black legs." The first-prize pen contained a cockerel with flesh-coloured legs and puckered earlobes, such as I have seen disqualified at many previous exhibitions (though the Judges may easily be exonerated from blame, for this class was unfortunately placed in the worst lighted part of the building), while several pens, the most perfect I ever saw, were passed over without notice. If puckered earlobes and flesh-coloured legs be an "improvement" in Black Bantams, then, in the humble opinion of your correspondent, we, like Paddy, are advancing backward.—Black Bantam.

After criticising the various classes up to No. 26, your correspondent goes on to say, "The cup for the best pen of Hamburghs fell to Mr. Beldon's Silver-pencilled, and they well deserved it." I say that it was a mistake, to say the least, as the cockerel had one of his sickle feathers dark and the other light, which ought to have been a disqualification for the cup, which might have been very safely awarded to the first-prize pen of adult Golden-spangled belonging to the same person, and I believe Mr. Beldon felt ashamed of the decision. As regards the Black Bantams, the cock in the first-prize pen had white legs, and was altogether a large bird. So much for the judging in these classes, and it would not be much trouble to go further with the mistakes in other classes.—J. W.

POULTRY CLUB.

Mr. Zurhorst, in your impression of January 1st, attaches my name to a series of false statements, which statements if adhered to, or repeated, he will probably find that he is not quite the immaculate being he thinks he is.—Edwd. Tudman, *Ash Grove, Whitchurch*.

PAISLEY ORNITHOLOGICAL ASSOCIATION SHOW.

The thirteenth annual Exhibition of the above Association was held on the 1st and 2nd inst., in the Volunteer Drill Hall, and was most successful. Upwards of 1200 birds were shown, and an unusually large number were sold.

Spanish.—First, J. Hutchison, Bishopton. Second, J. R. Rennards, Helensburgh. Third, W. Creelman, Kilmarnock. *Chickens.*—First and Cup, J. Fyfe, Rempock Point, Gonrock. Second, A. M'Lachlan, Paisley. Third, J. Crawford, Beith.

Dorkings (Coloured).—First, W. Reid, Hayston, Kirkintilloch. Second and Third, H. Heys, Springfield. *Chickens.*—First and Cup, R. Fulton, Cardross. Second and Third, J. Burns, Craigends.

Dorkings (White).—First and Third, J. Aitken, Paisley. Second, J. Pettigrew, Dalmellington.

Cochin-China.—Medal, First, and Second, J. Stuart, Helensburgh. Third, A. Paterson, Airdrie.

Brahma Pootra.—First and Second, A. Campbell, Blythswood. Medal, Brown & Cochran, Perth. Third, Major Smith, Janefield Place.

Old Scotch Breed.—First, A. Grant, Glentyan Mill. Second, J. M'Diarmid, Glasgow. Third, W. Thomson, Glasgow. Medal, R. Watson. Busby.

Hamburghs (Golden-spangled).—First, W Wotherspoon, Castlehead, Medal, Second, and Third, R. Cunningham, Stewarton.

Hamburghs (Golden-pencilled).—First and Medal, R. M'Gregor, Perth. Second, B. M. Richard, jun., Dumbarton. Third, A. M'Ewan, Stewarton.

Hamburghs (Silver-spangled).—Medal, First, and Third, J. Stewart, South Arthurlie. Second, A. Glen, Erskine.

Hamburghs (Silver-pencilled).—First and Medal, R. Calderwood, Stewarton. Second, A. Glendinning, Strathblane. Third, J. F. Hamson, Kendal.

Polands (Topped).—First, W. R. Menzies, Crossmyloof. Second, D. Murray, Eglinton Castle. Third, R. M'Nab, Cardonald.

Game (Black Reds).—First and Medal, J. H. M'Nab, Barrhead. Second, P. Alexander, Bridge of Weir. Third, J. Bryson, Hoggansfield.

Game (Any other colour).—First and Medal, J. J. Wilson, Darlington. Second, J. M'Indoe, Barrhead. Third, W. B. Menzies.

Any other Breed.—First and Third, W. White, Paisley. Second, W. R. Menzies.

Ducks (Aylesbury).—First and Second, H. Heys. Third, H. Jones, Aylesbury.

Ducks (Any other colour).—First, J. H. M'Nab. Second and Third, A. Grant, Kilbarchan.

Game Bantam.—First and Medal, W. Mahon. Jedburgh. Second, J. Sharp, Johnstone. Third, R. M'Gregor.

Bantams (Black).—First, A. Clelland, Crookitholm. Second and Third, J. C. Neilson, Airdrie.

Bantams (Any kind).—First and Medal, W. Morris, Paisley. Second, T. Knowles, Aberdeen. Third, W. Raeside, Irvine.

PIGEONS.

Powters.—*Blue.*—First and Medal, R. Fulton, London. Second, W. Lighthody, Glasgow. Third, G. White, sen., Paisley. *Black.*—First, J. Sharp, Johnstone. Second, R. Fulton. Third, G. White, sen., *White.*—First, R. Fulton. Second J. Sharp. Third, W. Neilson, Johnstone. *Any other colour.*—First, R. Fulton. Second, W. Lighthody. Third, G. White, jun.

Tumblers (Short-faced).—First, and Second, R. Fulton. Third, G. White, sen.

Tumblers (Common).—First and Second, J. Sharp. Third, J. Fielding, Rochdale.

Carriers (Any colour).—First and Second, R. Fulton. Third, G. White, sen.

FANTAILS.—First, J. Muir, Glasgow. Second, W. R. Park, Melrose. Third, J. Sharp.

JACOBINS.—First, G. White, sen. Second, J. Sharp. Third, F. Waitt, Birmingham.

NUNS.—First, W. R. Park, Melrose. Second, J. Sharp. Third, J. and D. Gray, Kilbarchan.

TURBITS.—F. Waitt. Second, G. Brown, Kilburnie. Third, J. Sharp.

PIGEONS (Common).—First, R. Stirrat, Dalry. Second, J. Glasgow, Dalry. Third, G. Brown.

ANY OTHER DISTINCT BREED.—First, J. Fielding. Second, G. White, jun. Third, J. Muir.

CANARIES.

PAIRS FOR SILVER CUP.—Cup, A. Kelly, Paisley. Second, W. Hunter, M. D., Kilbirnie. Third, T. Buchanan, Glasgow.

YELLOW.—*Cocks.*—First, D. Bell, Beith. Second, J. Mair, Kilmarnock. Third, G. Ayton, Glasgow. *Hens.*—First, J. Graham, Kilmarnock. Second, A. Mitchell, Paisley. Third, W. Harper, Paisley.

BUFF (*Cocks*).—First, J. Mair. Second and Medal, T. M'Motrie Third, H. Webster, Kilbarchan. *Hens* —First and Medal, W. Calderwood, Beith. Second, R. Hunter, Oakley. Third, D. Bell, Beith.

PAIR PIEBALD FOR MEDAL.—Medal, A. Kelly.

PIEBALD (Yellow).—*Cock.*—First, J. Wilson, Galston. Second, D. Duncan, Carron. Third, W. Hunter, Kilbirnie. *Hens.*—First, A. Kelly. Second, R. Hunter. Third, W. Hunter.

PIEBALD (Buff).—First, R. Hunter. Second, A. Crawford, Johnstone. Third, W. Sunter, Paisley. *Hens.*—First, T. G. M'Lean, Glasgow. Second, G. Haddow, Kilwinning. Third, J. Mathers, Glasgow.

GOLDFINCH MULE. First and Second, J. M. Laker.

GOLDFINCH.—First, G. Haddow. Second, J. Crawford.

HOME OR FOREIGN.—First, H. C. Agnew. Second, M. Andrew, Paisley.

JUDGES.—*Poultry:* Messrs. W. Farquhar, Barrhead; R. E. C. Benton, Darnlee; H. Todd, Paisley; J. Holburn, Stewarton; J. Stevenson, M.D., Ardrossan; J. Redpath, Edinburgh; J. Crawford, St. Rollox; and J. Hunter, Greenock. *For Pigeons:* Messrs. J. H. Frame, Carluke, and J. Paton, Stewarton. *For Canary Birds, &c.:* Messrs. W. Taylor, Glasgow; W. Orr, Beith; J. Wren, Pollokshaws; A. Brown, Stewarton; W. White, Renfrew; M. Wilson, Paisley; D. Buchanan, Paisley; and J. White, Paisley.

BRISTOL AND CLIFTON POULTRY EXHIBITION.

No poultry show could have been better conducted than the one just named, although it was the first meeting of the Society. A very brief glance, however, over the names, as published, of the Committee, twelve in number, proves that the whole of its members are known as being among the most noted of our poultry breeders and exhibitors, and, consequently, well aware of every requisite to insure success. All of them seemed most willing to aid by their own personal supervision, and the result was, that a Show so attractive in its general arrangements is very rarely to be seen. Another most favourable feature connected with the Show cannot possibly be passed by without favourable mention—viz., the extraordinary suitability of the Clifton Rifle Drill Hall to the purposes of a poultry show; in fact, if built expressly for that end alone, it could not be improved. The great extent of the building, and the perfect light throughout the whole was most gratifying, and although 789 pens were exhibited, double that number at any future Exhibition could, if requisite, be accommodated.

As might be expected, the classes for Black *Spanish* were quite worthy of the fame which the neighbourhood has so long enjoyed, as producing the best fowls of this variety in the kingdom, Messrs. Rodbard, Jones, and Lane, taking the three prizes in the adult class in the order named, with extraordinarily well-shown birds. In Spanish chickens no less than thirty pens competed, all good; in fact, so excellent a competition was, perhaps, never before submitted to the decision of public arbitrators. The Judges themselves, in an addendum to the prize list, say "that Nos. 20, 23, 38, and 42 were the best four pens ever seen." They belonged respectively to Messrs. Parsley, Roué, Lane, and Jones, all residing in the locality. It was to Mr. Parsley's chickens that the silver cup for the best pen of Spanish was awarded. In *Dorkings*, Bristol Show stood well, Lady Holmesdale showing a pen of old ones, that, though so long well known, seem to stand out as vigorous and perfect as ever. It is a proof both of combined careful management and very strong natural constitution, when Dorkings of such extreme size and weight remain eligible for competition after so many exhibitions. The triumph of this extraordinary pen of birds was, perhaps, greater than even on any previous occasion, as they gained a triple honour; being first in their own class; taking the silver cup, value five guineas, for "the best pen of Dorkings," and, as a still higher achievement, a cup for the "best pen of poultry in the whole Show," given regardless alike of breed or age. It is but justice to say, this largest cup was decidedly the best ever allotted to poultry, and though at first announced in the schedule as being of only ten-guineas value, its real worth exceeded that amount by several pounds. Lady Holmesdale seems to have reserved the strength of her poultry-yard for this express occasion, by also taking the second prize for adults, likewise both first and second prizes for Dorking chickens. Mr. Lingwood took both first and second prizes for White Dorkings. In Buff *Cochins* the Show proved very good; Mr. Fenton taking precedence in old birds, Colonel Wortley was second, and Mr. Cattell third. In chickens Mr. Chase was first, winning also the Buff Cochin cup, closely run by Mr. Mapplebeck, who secured both the second and third positions. In White Cochins Mr. Chase obtained the first prizes in both classes, consequently the White Cochin cup also. This gentleman's birds were exhibited in excellent condition. In *Brahmas* Mr. Boyle, of Dublin, was the successful one, the silver Brahma cup finding its future home in the Sister Isle. In speaking of *Game* fowls the name of Mr. Fletcher, of Stoneclough, appears in unvarying repetition. As to the rivalry in these classes, however, it must not for a moment be supposed that the entries were few, for on the contrary they far exceeded in numbers the generality of shows, as evidenced by the fact that Class 18, for Black or Brown Reds, contained seventy-one entries. Never could Game fowls be shown in a condition more creditable to the exhibitor, and we may mention that it was this cup pen of Game fowls that ran so closely for the principal cup, that the Judges were some considerable time in giving the preference. Sir St. George Gore's first-prize single Black Red Game cock was a most excellent bird. All the *Hamburgh* classes were far better than of late, the cup pen being a glorious trio of Golden-spangled, the property of Mr. Hyde, of Ashton-under-Lyne. The *Polish* class was one of the very best in the Exhibition. Mr. Kelleway, of the Isle of Wight, gained the Bantam cup with an exquisitely beautiful pen of Duckwings; it was, perhaps, the most admired of any of the pens of fowls in the Show. It is long since any others so good were exhibited, although evidently identical with the late winners at Brighton. The Black *Bantams* were particularly good, and some extraordinarily good Booted Bantams were shown.

Mrs. Seamons, Sir St. George Gore, and Mr. Leech, as customary, took precedence for *Ducks*, *Geese*, and *Turkeys*, in all of which classes the Bristol Show was well filled.

The untiring attention shown by every member of the Committee to the welfare of the valuable collection itself, as well as to the comfort and convenience of every spectator, is worthy of all praise. One of Brindley's patent incubators was on the spot. It is evidently somewhat novel in the mode of applying the heat, but, unfortunately, at the time of our visit was not in full operation.

SPANISH (Black).—First and Cup, J. R. Rodbard, Aldwick Court, Wrington. Second, E. Jones, Clifton. Third, H. Lane, Bristol. Highly Commended, E. Jones; W. Roue, Bristol. Commended, R. Wright, Holloway Road, London. *Chickens.*—First and Cup, D. Parsley, Kingsdown, Bristol. Second, W. Roue. Third, H. Lane. Very Highly Commended, E. Jones. Highly Commended, S. Healing, Borough Mills, Tewkesbury; E. Jones; C. Bell, Kingsdown; T. Bamfield, Bristol; Hon. Miss D. Pennant, Penrhyn Castle, Bangor; H. Lane; W. Roue; J. Davey, jun., Town Mills, Taunton; A. Heath, Calne, Wilts; J. R. Rodbard. Commended, E. Jones; Hon. Miss D. Pennant.

DORKINGS (Coloured).—First and Second, Cup for Best Pen of Dorkings, and Cup for the Best Pen of any variety, Viscountess Holmesdale, Linton Park, Staplehurst, Kent. Third, G. W. Cooper, Andum, Cheshire. Commended, C. Smith, Durnford, Salisbury; Mrs. Hargreaves, Arberfield Hall, Reading. *Chickens.*—First and Second, Viscountess Holmesdale. Third, J. H. Wilson, St. Bees.

DORKINGS (White).—First and Second, H. Lingwood, Barking, Needham Market, Suffolk. Third, T. P. Edwards, Lyndhurst, Hants. Commended, Rev. G. F. Hodgson, North Petherton near Bridgwater.

COCHIN-CHINA (Buff and Cinnamon).—First, A. Fenton, Crimble Hall, near Rochdale. Second, Col. Stuart Wortley, Grove End Road, London. Third, J. Cattell, Birmingham. Highly Commended, H. Tomlinson, Birmingham; A. Fenton. *Chickens.*—First and Cup, R. Chase, Balsall Heath, Birmingham. Second and Third, H. Mapplebeck, Woodfield, Moseley, Birmingham. Highly Commended, A. Fenton. Commended, Miss J. Millward, Newton St. Loe, Bristol; Mrs. W. G. Burnall, Mount Hill.

COCHIN-CHINA (Brown and Partridge).—First and Cup, A. Fenton. Second, E. Tudman, Ash Grove, Whitchurch, Salop. Third, J. Stephens, Walsall. Commended, A. Fenton. *Chickens.*—First and Third, E. Tudman. Second, J. R. Rodbard. Highly Commended, A. Fenton.

COCHIN-CHINA (White).—First and Cup, R. Chase. Second, L. Samuels, Horfield, Bristol. Third, Rev. W. J. Mellor, Colwick Rectory, Nottingham. Highly Commended, Rev. F. Taylor, Keastwick, Kirkby-Lonsdale. Commended, J. H. Wilson; W. Zurhorst, Belville, Donnybrook, Dublin. *Chickens.*—First, R. Chase. Second, J. Gardiner, Bristol. Third, F. D. Johnson, Lozells, Birmingham. Highly Commended, E. C. Boville, Willington, Burton-on-Trent.

BRAHMAS (Dark).—First and Cup, R. W. Boyle, Bray, Wicklow. Second, F. Sabin, Birmingham. Third, Col. Stuart Wortley. *Chickens.*—First, L. Wright, Kingsdown, Bristol. Second, R. W. Boyle. Third, H. Lacy, Lacy House, near Hebden Bridge. Highly Commended, Mrs. Hargreaves.

BRAHMAS (Light).—First and Second, J. Pares, Postford, Guildford, Third, E. Pigeon, Lympstone, near Exeter. *Chickens.*—First and Second, J. Pares. Third, F. Crook, Forest Hill.

MALAY (Any variety).—First, J. C. Cooper, Cooper's Hill, Limerick. Second, Rev. A. G. Brooke, Ruyton XI. Towns, Salop. Third, J. Hinton, Hinton, near Bath.

CRÈVE CŒUR.—First, W. Blinkhorn, Waterdale, near St. Helen's, Lancashire. Second, J. C. Cooper. Third, Col. Stuart Wortley. Highly Commended, J. Walker, Haya Park, Knaresborough.

GAME (Black-breasted and other Reds).—First and Cup and Second, J. Fletcher, Stoneclough, near Manchester. Third, W. Dale, Weston-super-Mare. Highly Commended, S. Dupe, Evercreech, near Bath; Sir St. G. Gore, Bart., Hopton Hall, Wirksworth, Derbyshire. Commended, Rev. F. Watson, Messing, Kelvedon, Essex.

GAME (Duckwings and other Greys and Blues).—First and Second, J. Fletcher. Third, H. M. Julian, White Friar-gate-bridge, Hull. Highly Commended, W. Bradley, Severn Navigation, Worcester; W. W. Pyne, South Lancing, Sussex; S. Dupe. Commended, W. Dale.

GAME (Any other variety).—First, J. Fletcher. Second, Sir St. G. Gore, Bart. Third, C. Bulpin, Riverside, Bridgwater.

HAMBURGHS Golden-pencilled).—First, H. Beldon, Goitstock, Bingley, Yorkshire. Second and Third, F. Pittis, jun., Newport, I.W. Highly Commended, J. E. Powers, Biggleswade; H. Pickles, jun., Earby, near Skipton.

HAMBURGHS (Silver-pencilled).—First, H. Beldon. Second, H. Pickles, jun. Third, J. E. Powers. Highly Commended, H. Beldon.

HAMBURGHS (Golden-spangled).—First, and Cup for Best Pen of Hamburghs of any variety, W. A. Hyde, Hurst, Ashton-under-Lyne. Second, J. Buckley, Taunton, near Ashton-under-Lyne. Third, I. Davies, Harborne, near Birmingham. Highly Commended, Messrs. S. & R. Ashton, Mottram, near Manchester; J. Roe, Hadfield, Manchester.

HAMBURGHS (Silver-spangled).—First and Second, J. Fielding, Newchurch, near Manchester. Third, H Beldon.

HAMBURGHS (Black).—First, G. Lingard, jun., Selly Oak, Birmingham. Second, T. Fletcher, Commissioner's Office, Great Malvern. Third, H. Beldon.

POLISH (Any variety).—First, H. Beldon. Second, Sir St. G. Gore, Bart. Third, T. P. Edwards. Highly Commended, J. Hinton; J. Percivall, Harborne, Birmingham; H. Beldon; G. C. Adkins, The Lightwoods, near Birmingham; Sir St. G. Gore, Bart. Commended, T. P. Edwards.

ANY OTHER DISTINCT VARIETY.—First, S. A. Wylke, East Mouseley, Surrey. Second, H. Lewerthy, Newport, Barnstaple. Third, R. H. Nicholas, Malpas, near Newport. Highly Commended, H. M. Maynard, Holmewood, Ryde, I.W.; P. P. Cother, Salisbury; Col. Stuart Wortley; J. C. Cooper; Mrs. S. Northcote, Upton Pyne, near Exeter.

GAME BANTAMS (Black-breasted and other Reds).—First and Second, H. Shumack, Southwell, Notts. Third, C. Harris, Maindee Park, near Newport, Mon. Highly Commended, G. Griggs, Oaklands, near Romford, Essex; Rev. A. K. Cornwall, Bencombe, Dursley; E. Joynson, Liscard, Cheshire; R. Swift, Southwell, Notts; Miss E A. Crawford, Farnsfield, Southwell; Sir St. G. Gore, Bart.; A. Fenton. Commended, S. Lang, jun., Barrow Gurney, near Bristol.

GAME BANTAMS (Any other variety).—First, and Cup for Best Pen of Bantams of any variety, J. W. Kelleway, Merston, I.W. Second, W. S. Forrest, Eagle Cliff, Greenhithe, Kent. Third, Mrs. Saltmarsh, Chelmsford. Highly Commended, Misses R and E. Todder, Little Carlton, near Newark, Notts. Commended, H. Dowsett, Pleshey, Chelmsford; Sir St. G. Gore, Bart.

BANTAMS (Gold and Silver Sebright).—First, M. Leno, Dunstable. Second and Third, U Spary, Dunstable. Highly Commended, Messrs. S. and R. Ashton; M. Leno; Rev. G. S. Cruwys, Tiverton, Devon.

BANTAMS (Black, clean-legged).—First, E. Cambridge, Stoke's Croft Road, Bristol. Second and Third, H. M. Maynard. Highly Commended, Mrs. H. Freke, Highworth, Wilts; E. Cambridge.

BANTAMS (White and any other variety).—First, G. Griggs. Second, J. R. Jessop, Beverley Road, Hull. Third, L. Samuels. Highly Commended, W. Osmond, Dorchester.

DUCKS (White Aylesbury).—First, Mrs. M. Seamons, Hartwell, Aylesbury, Bucks. Second, H. Jones, Dinton, Aylesbury. Highly Commended, J. Logan, Maindee House, near Newport, Mon.; S. Lang, jun.; Mrs. M. Seamons.

DUCKS (Rouen).—First, E. Leech, Rochdale. Second, C. A. Nichols, Yatton, near Bristol. Highly Commended, W. Peach, Tockington, Gloucestershire; G. M. Hulbert, Perott Brook, Cirencester; J. R. Rodbard.

DUCKS (Any other variety).—First, Sir St. G. Gore, Bart. Second, A. Fenton. Highly Commended, T. C. Harrison, Beverley Road, Hull; L. Samuels; G. W. Harrison, Spalding.

GEESE (Any variety).—First, Mrs. M. Seamons. Second, A. Sperrin, Bitton. Highly Commended, Mrs. Laver, Hewish, near Congresbury, Bristol; Mrs. Matthews, Aredunnock, near Usk, Mon.; A. Sperrin; J. C. Cooper.

TURKEYS (Any variety).—First, E. Leech. Second, S. Lang, jun. Highly Commended, B Sherratt, Taynton, near Gloucester; J. Logan. Commended, C. Edwards, Wrington, Somerset; J. C. Cooper.

SINGLE COCKS.

SPANISH (Black).—First and Cup, T. J. Perry, Bristol. Second, W. Rone. Very Highly Commended, T. Cliff, Hanley, Staffordshire. Highly Commended, E. Jones; R. Wright; H Lane. Commended, T Bamfield.

DORKING (Any variety).—First, H. Beldon. Second, J. C. Cooper. Highly Commended, S Onley, Cheltenham; Hon. Miss D. Pennant; J. Fox, St. Bees, Cumberland; L. Patton, Taunton; F. Porlett, Great Baddow, Chelmsford; B. Johnson, Langley Burrell, near Chippenham. Commended, Rev. E. Cadogan, Walton Parsonage, Warwick.

COCHIN-CHINA (Buff and Cinnamon).—First, Col. Stuart Wortley. Second, H. Mapplebeck. Highly Commended, H. Mapplebeck. Commended, Hon. Miss D. Pennant.

COCHIN-CHINA (Any other variety).—First, Messrs. Keal & Phillips, Westbury-on-Trym. Second, A. Fenton.

GAME (Black-breasted and other Reds).—First, Sir St. G. Gore, Bart. Second, J. Fletcher. Highly Commended, T. Dyson, Halifax. Commended, H. Thompson, Hilmarton, Calne, Wilts; Rev. G. S. Cruwys.

GAME (Any other variety).—First and Second, Sir St. G. Gore, Bart.

HAMBURGHS (Spangled).—First, W. Barrstow, Ferncliff, Bingley, Yorkshire. Second, I. Davies.

HAMBURGHS (Pencilled).—First, H. Beldon. Second, H. Pickles, jun.

BRAHMA POOTRA (Any variety).—First, R. W. Boyle. Second, E Joynson. Highly Commended, L. Wright. Commended, C. S. Lambert, Kingswood, Bristol.

GAME BANTAMS (Any variety).—First, Sir St. G. Gore, Bart. Second, A. Fenton. Highly Commended, Sir St. G Gore, Bart.; A. Fenton.

BANTAMS (Any other variety).—First, J. W. Morris, Rochdale, Lancashire. Second, S. Lang, jun., Barrow Gurney, near Bristol. Highly Commended, Rev. F. Tearle, Gazeley Vicarage, Newmarket. Commended, M. Leno.

Mr. Edward Hewitt, of Sparkbrook, Birmingham, and Mr. John Douglas, of Clumber Park, Notts, officiated as Judges.

WENTWORTH POULTRY EXHIBITION.

THIS Exhibition was held on Saturday, the 29th, and Monday, the 31st of December, and it would be an injustice were we not to accord our highest praise to the management of the Committee. Every effort was made to insure success, and this end was duly achieved by the collection of a show of poultry that would have done credit to any county of the kingdom. The Riding School, in which the Show was held, is a building that is most peculiarly well adapted to the purposes of a poultry show; in fact, not thus less eligible than for the uses for which it was originally intended—as a Riding School. The only drawback to the whole proceedings was the circumstance that the Committee, having a long time ago engaged the pens of Messrs. Turner, of Sheffield, were through a delay in transit from the Limerick Show, compelled to adopt the most speedy measures to have everything ready for their own meeting, and fortunately having a large number of pens remaining from former meetings, they at once raised about the half of the number of the pens wanted from resources directly at command. As Masborough is so near to Sheffield, we would suggest to the Messrs. Turner the propriety of having at instant disposal a number of extra pens on hand, to meet every emergency for the future, as any want of fulfilment of engagement is a matter of the most serious import to poultry committees, thus thrown out of gear in arrangements over which they cannot possibly have any command. As the income per annum by per-centage on outlay from letting these pens is so favourable to the Messrs. Turner, we do not for a moment doubt this friendly hint on future management will be duly attended to, more particularly as the pens when they arrived were placed in the background unused, and at that hour unwanted.

The *Dorkings* constituted a collection of unusual excellence, although we regretted to see many otherwise most excellent pens with the spurs fixed outside the legs in one or two of the inmates, a very fatal defect. The Dorkings, as a whole, were a most favourable feature, but numbers of the chickens were thrown out by the radical malformation just alluded to. Breeders of Dorkings cannot be too careful on this point. The *Cochins* were most creditable, as were also the *Brahmas* It appears that although the last pens put up at Wentworth were of these classes, they stood the additional trial without any difficulty. The *Game* generally were of high repute, and the Hon. W. C. Fitzwilliam's Brown Red Game cock seemed alike capable of testing his individual superiority in the exhibition or the cock-pit. A bird in more unexceptionable condition has been rarely exhibited. The *Spanish* classes were, undoubtedly, very good, although we saw, with regret, many specimens that from being the first-rates of their day, were, by age and over-exhibition, rendered only fit to be put aside as castaways. The *Hamburghs* were, as expected, generally good; and the *Polands* so good a class that every pen, though unsuccessful in prizetaking, was highly commended. In truth, it was the best Poland class seen anywhere for years past. Although the *Game Bantams* wanted condition most sadly, the class for the "extra variety of Bantams," proved one of the gems of the Show; capital Cochin Bantams, Japanese Bantams (both Mottled and White) of extraordinarily good quality, Booted Bantams, and Golden and Silver-laced Sebrights, being entered here abundantly.

In *Ducks*, though somewhat unusually, Aylesbury and Rouens competed in the same class. Aylesburys had, undoubtedly, the advantage, and were shown in a condition that could hardly have been complained of, even by the most critical exhibitor.

The French Fowls were shown in large numbers, and, perhaps, never were two pens of La Flèche fowls exhibited so evenly matched for prizetaking. Both were the property of the Hon. W. H. Fitzwilliam, and the slightest alteration in condition must always tell favourably with them as to their position in the prize list.

Wentworth Woodhouse Park, a favourite resort in the locality, was not neglected at this meeting; the attendance was good, and the weather most favourable; nor can we omit to mention that the great care bestowed on the poultry merits our highest praise. The efforts, also, of Mr. H. Potter, the Hon. Sec. of the Show, realised all it so well deserved—unanimous approbation.

DORKINGS.—First, Hon. W. H. W. Fitzwilliam, Wentworth Woodhouse. Second, W. Harvey, Bank Street, Sheffield. Highly Commended, G. W. Chambers, Clough House, Rotherham; Hon. E. D. Pennant, Penrhyn Castle. Commended, Hon. F. C. H. Hawke, Wormersley Park, Pontefract; Lady C. W. Fitzwilliam, Harrowden House, Wellingborough. *Chickens.*—First, M. Brooksbank, Manchester. Second, Rev. G. C. Stenning, East Grinstead. Highly Commended, J. White, Warlaby, Northallerton.

COCHINS.—First, R. White, Broomhall Park, Sheffield. Second, W. Fenton, Crimble Hall, Rochdale. Highly Commended, W. Fenton; W. Dawson, Hopton Mirfield; W. Harvey. Commended, Hon. E. D. Pennant; W. Wood, Sheffield. *Chickens.*—First, W. Fenton. Second, R. White. Highly Commended, W. Fenton.

BRAHMAS.—First, R. W. Boyle, Galtrim House, Bray, Co. Wicklow. Second, W. Harvey. Highly Commended, W. Whiteley, East Bank, Sheffield; F. Powell, Knaresborough; J. K. Fowler, Prehendal Farm, Aylesbury. Commended, E. Sheerman, Springfield, Chelmsford. *Chickens.*—First, R. W. Boyle. Second, J. K. Fowler. Highly Commended, G. W. Chambers; F. Powell; J F. Newton, Kirby-in-Cleveland; M. Brooksbank. Commended, Hon. F. C. H. Hawke; Mrs. Newman, Worsbro', Barnsley.

GAME (Reds).—First, Earl Fitzwilliam, Wentworth Woodhouse. Second, W. J. Cope, Barnsley. Highly Commended, R. Butcher, Cresswell, Chesterfield; J. B. Hepworth, Hatfield, Doncaster; C. Chaloner, Steetley, Whitewell, Chesterfield. *Chickens.*—First, C. Chaloner. Second, F. Sales, Market Place, Crowle. Highly Commended, W. Cox, Brailsford Hall, Derby. Commended, E. Aykroyd, Girlington Road, Bradford.

GAME (Any other variety).—First, H. Snowden, Great Horton, Bradford, (Duckwing). Second, W. J. Cope (Duckwing). Highly Commended, R. Butcher (Piles). *Chickens.*—First, J. Cope (Duckwing). Second, Rev. G. C. Stenning (Duckwing). Commended, C. Chaloner.

SPANISH.—First, Messrs. Burch & Boulter, Sheffield. Second, J. B. Hartley, Roe Acre House, Heywood, Manchester. Highly Commended, W. Harvey; J. Thresh, Bradford. Commended, Rev. W. J. Mellor, Colwick Rectory, Nottingham. *Chickens.*—First, Hon. E. D. Pennant. Second, Messrs. Burch & Boulter. Highly Commended, J. Thresh.

HAMBURGHS (Silver-pencilled).—First, W. Harvey. Second, I. J. Harrison, Smyleton Park, Oxenholm. Highly Commended, T. J. Saltmarsh

Chelmsford; B. Heaton, Bingley, Yorkshire; I. J. Harrison. Commended, W. Cox.

Hamburghs (Golden-pencilled).—First, T. Crookes, Owlerton. Second, W. Harvey. Commended, J. Crookes.

Hamburghs (Silver-spangled).—First, W. Harvey. Second, J. Crookes. Commended, Hon. W. C. W. Fitzwilliam.

Hamburghs (Golden-spangled).—First, G. Haigh, Holmfirth. Second, W. Harvey. Highly Commended, J. Roe, Hadfield, Manchester.

Polands.—First, R. Charlesworth, Brooks' Bar, Manchester. Second, Mrs. Procter, Hutt Street, Hull. Highly Commended, W. Silvester, Springwood House, Sheffield; J. Longley, Penistone; Mrs. Proctor; W. Harvey.

Any other Variety not Previously Mentioned.—First, Hon. W. H. W. Fitzwilliam (La Flèche). Second, Hon. W. C. W. Fitzwilliam, Wentworth Woodhouse (La Flèche). Highly Commended, Lady M. Thompson, Sheriff Hutton Park, York (Crève Cœur); H. Saville, Rufford Abbey, Ollerton (Black Hamburghs); J. Elgar, Osmanthorpe, Newark (Houdan).

Game Bantams.—First, R. Charlesworth. Second, Rev. W. J. Mellor. Highly Commended, J. Parkin, Clay Cross; W. Parker, Clay Cross; J. Ewing, Tufton, Chesterfield; R. Bentley, Finningley Park, Bawtry; W. Fenton.

Bantams (Any other variety).—First, W. Harvey. Second, S. S. Mossop, Long Sutton, Lincolnshire. Extra Second, R. Bentley. Highly Commended, Messrs. S. & R. Ashton, Mottram; W. Parker; Lady C. W. Fitzwilliam; W. J. Cope; H. Saville. Commended, Mrs. Saltmarsh, Chelmsford.

Ducks (Aylesbury or Rouen).—First, Hon. W. H. W. Fitzwilliam (Aylesbury). Second, Hon. F. C. H. Hawke (Rouen). Highly Commended, Messrs. Burton & Traviss, Thurgoland Bank, Sheffield; F. G. Godwin (Ronen); Hon. W. H. W. Fitzwilliam (Aylesbury); J. K. Fowler (Aylesbury). Commended, Lady M. Thompson (Aylesbury); F. Powell (Rouen); W. Dransfield (Rouen); W. Clarke, Wentworth (Aylesbury).

Selling Class (Any variety).—First, Hon. W. H. W. Fitzwilliam (Crève Cœurs). Second, J. Thornily, Hadfield, Manchester (Cochins). Highly Commended, H. Saville (White Call); W. Dransfield (Dorkings); Hon. W. C. W. Fitzwilliam (Silver-spangled Hamburghs).

SWEEPSTAKES FOR SINGLE COCKS.

Game.—First, C. Chaloner. Second, G. Wostenholme, Exchange Street, Sheffield. Highly Commended, C. Turner, Carlisle Street, Sheffield. Commended, W. J. Cope. *Cockerel.*—First, W. J. Cope. Second, F. Sales. Commended, G. Wostenholme.

Game Bantam.—First, F. S. Roy, Nenthorn, Kelso. Second, R. Charlesworth. Commended, R. Swift, Southwell, Notts.

Game (Undubbed).—Prize, W. Cox. Commended, C. E. Rhodes, Car House, Rotherham; C. Chaloner.

The Arbitrator was Edward Hewitt, Esq., of Eden Cottage, Sparkbrook, Birmingham.

LANGHOLM POULTRY SHOW.

The Exhibition of the Eskdale Society took place on the 1st and 2nd inst., and the following prizes were awarded:—

Game (Any colour).—First, J. H. Wilson, St. Bees. Second, J. Brough, Carlisle. Third, A. Thomson, Carlisle. Highly Commended, J. Brough; J. Hardie.

Game (Black or Brown-breasted Reds).—First, A. Thomson, Harraby Green. Second, G. Bell, Wigton. *Chickens.*—First, G. Dobson, Longtown, Second, A. Thomson.

Game (Duckwings or Piles).—First, A. Thomson. Second, J. Brough. *Chickens.*—Second, J. Brough (Lemon Pile).

Spanish.—First, J. Huesh, Bradford. Second, W. Paterson, Langholm. *Chickens.*—First, W. Paterson. Second, J. Hardie. Highly Commended, W. Paterson; J. Strong, Carlisle. Commended, A. Ballantyne, New Langholm.

Dorking (Silver).—First, J. Hardie. Second and Highly Commended, T. L. Jackson, Bush. *Chickens.*—First and Second, J. Hardie. Highly Commended, J. H. Wilson.

Dorkings (Dark).—First, Miss Malcolm, Milnholm. Second, J. Hardie. Highly Commended, T. L. Jackson. *Chickens.*—First, R. Reed, Moat. Second, J. Hardie. Highly Commended, D. Gellatly, Meigle.

Hamburghs (Golden-spangled).—First, A. Hatelie, Selkirk. Second, S. Hyslop, Langholm. *Chickens.*—First, W. Blackstock, Corriecommon. Second, J. Long, Longtown. Highly Commended, J. H. Wilson.

Hamburghs (Golden-pencilled).—First, W. Bowe, Carlisle. Second, R. Burrow. *Chickens.*—First and Second, R. Burrow. Highly Commended, J. Hardie.

Hamburghs (Silver-spangled).—Prize, W. Bowe. *Chickens.*—First and Second, J. Hargraves, Carlisle. Highly Commended, W. Davey, Langholm. Commended, G. Macmilan, Jedburgh.

Hamburghs (Silver-pencilled).—First, T. Harrison, Singleton Park. Second, J. Musgrave, Longtown. *Chickens.*—First, J. Musgrave. Second, H. Greenwood, Bradford.

Cochin-Chinas.—First, Mrs. W. Ford, Harden Green (White). Second, Messrs. Bowman & Fearon, Whitehaven. Highly Commended, J. Hardie (Buff). Commended, W. R. Park, Abbotts Meadow.

Brahma Pootra.—First, Messrs. Bowman & Fearon. Second, Miss M. Jardine, Albie Hill.

Any other Different Breed.—Second, W. R. Park (Crève Cœur). Highly Commended, R. Plendericith, Longtown.

Game Bantams (Black or Brown-breasted Reds.)—First, J. Hervey, Jedburgh. Second, A. Thomson. Third, H. Nicholson, Whitehaven.

Game Bantams (Duckwing or Piles).— First, W. Easton, Jedburgh (Duckwings). Second, D. Little, Broomholm. Third, J. Lunn, Jedburgh.

Any other Variety of Fancy Bantams.—First, J. A. Robinson, Sunderland. Second, T. Little, Netherby Gardens. Third, R. Burrow. Highly Commended, J. Wallas, High Moor, Wigton.

Turkeys.—First, J. Hardie. Second, Mrs. Jackson, Bush, Langholm. Highly Commended, R. Reed; T. L. Jackson. Commended, Miss Maxwell, Harlewhill. *Poults.*—First, T. L. Jackson. Second, J. Hardie. Very Highly Commended, Miss Malcolm, Milnholm, Langholm. Highly Commended, R. Reed; J. Hardie.

Geese.—First and Second, J. Hardie. Highly Commended, — Dickson, Lokerbie.

Ducks (Aylesbury).—First, T. Paterson, jun., Melrose. Second, J. Steel Kelso. Highly Commended, W. Macadam, Priorslynn; J. Hardie.

Ducks (Rouen).—First and Second, J. Hardie. Highly Commended, A. Warwick, Woodhead.

Ducks (Any other variety).—First, J. R. Jessop, Beverley Road, Hull. Second, Miss Bell, Billholm. Highly Commended, T. J. Harrison; J. R. Paterson.

COTTAGERS' CLASS.

Any Breed.—First, W. Urquhart, jun. (Dorkings). Second, A. Ballantyne (Spanish). Third, J. Laidlaw (Spanish). Highly Commended, W. Bole (Hamburgh); A. Rea (Dorkings); J. Corrie (Game).

Any Breed.—First, R. Latimer, Forgebraehead. Second, Miss C. Graham, Blisspath. Third, Mrs. Armstrong, Kirkton. Highly Commended, C. Beattie, Bush Cottage; Mrs. Harvey, Sorbie Cottage. Commended, W. Gordon Milnholm; T. Irving.

Selling Class.—First, R. Burrows. Second, J. Brough. Highly Commended, A. Thomson; G. Mackie, Purdoms Crook; T. L. Jackson.

Single Cock.—Highly Commended, R. Bell (Wild Drake). Commended, J. Laidlaw (Brahma Pootra); S. Hyslop (Hamburgh); T. L. Jackson (Indian Drake).

PIGEONS.

Choppers.—First, J. A. Robinson. Second, W. Cheyne, Selkirk. Highly Commended, A. Thomson; J. Campbell, Langholm Distillery.

Jacobins.—First, R. Thomson, Kendal. Second, T. C. Taylor, Middlesborough.

Fantails.—First, W. R. Park. Second, T. C. Taylor.

Carriers.—First, A. Thomson. Second, T. C. Taylor.

Barbs.—First, R. Thompson. Second, J. A. Robinson. Highly Commended, A. Thomson.

Nuns.—First, R. Paterson, Melrose. Second, R. Irving, Langholm. Highly Commended, A. Thomson; T. Paterson, jun.

Turbits.—First, R. Thomson. Second, W. R. Park. Highly Commended, A. Ormiston, Kelso.

Any other Variety.—First, A. Thomson. Second, W. R. Park. Highly Commended, A. Thomson; J. Campbell. Commended, F. Waitt, Birmingham; T. Taylor.

Selling Class.—First, W. R. Park (Fantails). Second, J. Campbell. Highly Commended, R. Paterson (Turbits).

CANARIES.

Scotch Fancy (Yellow Don).—*Cock.*—First, H. M'Dougal, Edinburgh. Second, R. Ballantyne. *Hen.*—First, H. M'Dougal. Second, W. Tinline, Galashiels.

Scotch Fancy (Buff Don).—*Cock.*—First, H. M'Dougal. Second, J. R. Thomson. *Hen.*—First, H. M'Dougal. Second, R. Ballantyne.

Belgian (Yellow).—*Cock.*—First, H. Carlyle, Carlisle. Second, W. Tinline. *Hen.*—Second, H. Carlyle.

Belgian (Buff).—*Cock.*—First, H. Carlyle. Second, A. Beattie. *Hen.*—First, W. Tinline. Second, W. Macadam, Priorslynn.

Yellow Flecked Fancy.—*Cock.*—First, J. Cleghorn, Galashiels. Second, T. Darling, Hawick. *Hen.*—Second, J. Dalgliesh.

Buff Flecked Fancy.—*Cock.*—First, R. Paterson. Second, J. Hope. *Hen.*—First, W. Tinline. Second, W. Balmer, Hawick.

GOLDFINCH MULES.

Yellow Flecked.—*Cock.*—Prize, R. Graham, Rowanburn.

Buff Flecked.—*Cock.*—First, J. C. Wilson, Langholm. Second, R. Graham.

Yellow Common.—*Cock.*—Prize, R. Graham. *Hen.*—Second, R. Graham.

Buff Common.—*Cock.*—Second, R. Graham. *Hen.*—First, W. Balmer, Bawick. Second, W. Morrison, Langholm.

Yellow Flecked Common.—*Cock.*—First, W. Hotson, Milnholm. Second, W. Morrison. *Hen.*—First and Second, W. Hotson.

Buff Flecked Common.—*Cock.*—Second, W. Clark, Langholm. *Hen.*—Second, J. Hope.

Goldfinch.—*Cock.*—First, R. Graham. Second, W. Hotson.

ALSTON POULTRY SHOW.

This Exhibition was held on the 22nd of December, 1866, in the Town Hall, where some capital pens of birds were exhibited, especially in the *Game, Spanish, and Hamburgh classes.*

Game (Black-breasted and other Reds).—First, J. Haldon, jun., Alston. Second, J. Stephenson, Nenthead. *Chickens.*—First, Walton & Gray, Annatwalls. Second, J. Haldon, jun.

Game (Any other variety).—First, G. Wilson, Kirkoswald. Second, Millican & Brown, Nenthead. *Chickens.*—First, G. Wilson. Second, E. Armstrong, Randal, Holme.

Dorkings.—First, W. Walton, Cocklake. Second, T. Bowes, Kirkoswald. *Chickens.*—Prize, G. Graham, Garrigill.

Spanish.—First, T. Storey, Alston. Second, J. Jopling, Leadgate. *Chickens.*—First, W. Arthur, Haltwhistle. Second, T. Storey.

Hamburghs (Gold-pencilled or spangled).—First, T. Richardson Goatley Hill. Second, T. Greenop, Renwick. *Chickens.*—First, Walton and Rutherford, Green Ends. Second, J. Dryden, Alston.

Hamburghs (Silver-pencilled or spangled.—First, Walton & Rutherford. Second, Miss Friend, Harbut Lodge. *Chickens.*—First, J. Stephenson, Nenthead. Second, Walton & Rutherford.

Cochin-China.—First and Second, J. Dryden.

Polish.—First, Walton & Rutherford. Second, Millican & Brown.

Bantams.—First, F. Clementson, Alston. Second, T. Bowes.

Any other Pure Breed.—First, J. Dryden (Brahma Pootra). Second, T. Peart, Garrigill.

Duck (Aylesbury).—First W. Lowry, Featherstone Station. Second, J. & J. Kindred, Bailes. *Duckling.*—First and Second, Miss Friend.

Duck (Rouen).—First, J. Thompson, Sun Inn, Haltwhistle. Second, I. Walton, Brownside House. *Duckling.*—First, G. Rutherford, Nenthead.

Extra stock.—*Goose.*—First, J. Thompson. Second, I. Walton.—*Fowls.*—First and Second, J. Dryden. *Rabbits.*—First, Master H. James, Glarghyll Hall.

Canary (Belgian).—Prize, J. Millican, Alston.

Canary (Yellow and Buff).—First, J. Stephenson. Second, Millican and Brown.

Canary (Yellow and Buff marked).—First, R. Walton, Nenthead. Second, W. Bell, Alstyn.

Goldfinch Mule.—Prize, Millican & Brown.

Mr. Trotter, of South Acomb, was Judge of poultry, and Mr. Thomas Richardson, of Kirkoswald, made the awards for Canaries.

DUMFRIES AND MAXWELLTOWN ORNITHOLOGICAL SOCIETY'S EXHIBITION.

The eighth annual Exhibition of Poultry, Pigeons, Canaries, &c., of this Society, was held in the Hall of the Mechanics' Institute, on December 31st and January 1st and 2nd. The various birds, &c., were placed on the forenoon of the 31st ult., but as some pens did not arrive by railway till nearly one o'clock, the Judges could not commence their labours till after that hour. A very great improvement on previous shows was that pens were provided for all the poultry, except in the Bantam classes.

The Show was decidedly the best that has taken place since the Society was instituted. The show of poultry was much larger than last year; total entries 385.

Of *Game* fowls there was a splendid show of Black Reds and other Reds. There was a smaller show of Duckwings and other Greys, but the class in both departments was very good. There was a smaller show of *Spanish* than last year. The first prize in the adult class went to a very superior pen. The *Dorkings* were numerously represented. Miss M. A. Johnstone, Terregles Gardens, gained the first prize with a very choice pen, which received the first prize last year as young birds. They have never been equalled at any preceding show. The *Hamburghs*, both Golden and Silver varieties, mustered in great force; and there were many very beautiful pens. Of *Brahma Pootras* there was an excellent show.

The *Ducks* were more numerous than last year, and the whole of the pens were very good. Only two pens of *Geese* were shown; the prize birds were pure white, and were of large size and handsome shape—they were universally admired. The other pair was grey; they were larger than the white, and were very fine specimens. The *Turkeys* were scarcely equal to those of some former shows. *Bantams* were not so numerous as last year.

Pigeons were also fewer in number than last year, but there were some beautiful Doves exhibited.

The arrangements reflected great credit on the indefatigable Secretary, Mr. John Maxwell, and the members of the Committee.

Game (Black Reds and other Reds and Blues).—First and Second, W. D. Dickson, Carron Croft. Highly Commended, T. Taylor, Riccarton, Kilmarnock. *Chickens.*—First and Medal, J. Carr, Longtown. Second, W. D. Dickson. Highly Commended, W. Bowie. Commended, R. Kerr.

Duckwings and other Greys.—First, J. Davidson, Citadel Row, Carlisle. Second, C. Graham, Dumfries. Highly Commended, J. Biggar, Gateside-of-Trench. *Chickens.*—First, J. Harding, Maxwelltown. Third, T. Hill, Collin. Highly Commended, M. Wells, Collin.

Spanish (Black).—First, Miss Biggar, Braes House, Ecclefechan. Second, J. Thomson, Cocklicks, Annan. *Chickens.*—First and Medal, Miss Biggar. Second, R. J. Linton, Kirkmahoe.

Dorkings.—First and Medal, Miss M. A. Johnstone, Terregles Gardens. Second, W. F. H. Arundell, Barjarg Tower. Highly Commended, J. Pool, Croftheads, Annan; J. M'Kenzie, Barnhill. *Chickens.*—First, Miss M. Holm, Hillhead. Second, W. F. H. Arundell. Highly Commended, Mrs. Corrie, Heithat Hill, Lockerbie; Miss A. J. Douglas, Lockerbie House. Commended, Miss M. A. Johnstone.

Cochin-China (Any colour).—First, Miss Biggar. Second, W. Cowan, Clarancefield. Highly Commended, A. Reid, Newtoureid. *Chickens.*—First, Lady J. J. Douglas, Lokerbie House. Second, Miss Biggar. Highly Commended, Mrs. Mackie, Ernespie.

Hamburgh (Golden-spangled).—First and Medal, Mrs. Corrie. Second, T. Musgrove, Longtown. Highly Commended, J. Richardson, Lockerbie; A. M'Lean, Ruthwell. *Chickens.*—First, Miss Biggar. Second, H. Currie, Ardrossan. Highly Commended, Mrs. Corrie; R. Kerr.

Hamburgh Golden-pencilled.—First, R. Burrow, Longtown. Second, J. Ramsay, Carnsalloch. Commended, J. Mallinson, Dalbeattie. *Chickens.*—First, W. Bowie, Carlisle. Second, T. Musgrove. Highly Commended, W. Wallace, Kirkmahoe. Commended, T. Johnstone, Waterside.

Hamburgh (Silver spangled).—First, J. Hunter, Gatelawbridge. Second, J. Hutchison, Townhead, Mouswald. Commended, R. Chrystie, Dumfries. *Chickens.*—First and Medal, A. M'Lachlan, Thornhill. Second, Mrs. Deans, Drumlanrig Castle. Highly Commended, Mise Ross, Springfield, Applegirth. Commended, R. Kerr.

Hamburgh (Silver-pencilled).—First, J. Musgrove. Second, J. Thomson, Nethermill, Kirkmichael. *Chickens.*—First, N. Wilson, Croys. Second, R. Hannay, Tarff Bridge. Commended, J. Musgrove.

Brahma Pootras.—First, Mrs. Waugh, Castlehill, Lochmaben. Second, Mrs. Greig, Kirkpatrick, Durham. *Chickens.*—First, Mrs. Gordon, Culvennan. Second, W. W. Anderson, Chapel Moffat. Highly Commended, Mrs. Gordon.

Any other Variety.—First and Second, Mrs. Gordon (Houdan, Crève Cœur).

Selling Class.—First, Miss Biggar (Black Spanish). Second, T. Maxwell, Allanton Mill (Dorkings).

Bantams (Golden and Silver-laced).—First, Miss Johnstone. Second, W. W. Anderson.

Bantams (Black).—First and Medal, R. Murray, Maxwelltown. Second R. Watts, Craigs.

Bantams (White).—First, W. Teenan, Lochside. Second, J. Maxwell, Allanton Mill. Commended, H. Robinson, Riccarton, Kilmarnock.

Game Bantams Black Reds and other Reds.—First, C. Harper, Thornhill. Second, T. Maxwell. Commended, R. Coltart, Dumfries.

Game (Duckwings and other Greys).—First, T. Maxwell. Second, R. Hope, Dumfries.

Any other Variety.—First, J. Palmer, Maxwelltown. Second, A. Andersen, Ryedale.

Ducks (Aylesbury).—First, Miss A. J. Douglas. Second, T. Johnstone, Waterside. Commended, Mrs. Gordon.

Ducks (Rouen).—First, Mrs. Thomson. Second, J. Boyd, Southwick.

Geese (Any variety).—First, J. Brown, Ingleston. Second, J. Pool.

Turkeys (Any variety).—First, Mrs. Henderson. Second, Mrs. H. Wilson, Langholm.

Pigeons.—*Tumblers* (Short-faced).—First, J. Sharp, Johnstone. Second and Commended, R. Henderson, Maxwelltown. *Common.*—First, J. Sharp. Second, J. Love, Dumfries. Commended, J. Kennedy, Dumfries. *Carriers.*—First, J. Sharp. Second, T. Maxwell. *Powters.*—Prize, J. Sharp. *Fantails.*—First, R. Maisie, Maxwelltown. Second, A. Easton, Lochanhead. *Any other Distinct Breed.*—First, J. Sharp, (Black Magpies). Second, J. Thomson (Earbs). Commended, C. Harper (Trumpeters).

CANARIES.

Scotch Fancy (Yellow).—*Cocks.*—First, Second, and Medal, J. Harding, Maxwelltown. Third, J. Thorpe, Dumfries. *Hens.*—First and Third, J. Harding. Second, J. Thorpe.

Scotch Fancy (Buff).—*Cocks*—First, J. Harding. Second and Third, J. Thorpe. *Hens.*—First, J. Thorpe. Second, J. Harding. Third, J. M'Quhae, Maxwelltown.

Piebald (Yellow).—*Cocks*—First, Third, and Medal, J. Law, Lockerbie. Second, J. Thorpe. *Hens*—First, J. Law. Second and Third, J. Thorpe.

Piebald (Buff)—*Cocks*—First, J. Law. Second, J. Thorpe. Third, R. M'Cubbin, Annan. *Hens.*—First, J. Thorpe. Second, J. Law. Third, J. Little, Dumfries.

Belgian (Yellow or Buff)—First, J. Tweedie, Lochmaben. Second, T. Whitaker, Lochmaben. Third, J. Mallinson, Dalbeattie. *Hens.*—First and Third, T. Whitaker. Second, J. Mallinson.

Goldfinch Mules (Yellow).—First, A. K. Herries, Dumfries. Second, J. Kirk, Dumfries.

Goldfinch Mules (Buff).—First, J. Law. Second and Third, J. Harding, Maxwelltown.

Goldfinch.—First, D. Aitkinson. Second, C. Grieve, Dumfries. Third, J. Wilson, Dumfries.

Foreign Birds.—*Parrot, any colour.*—Prize, W. Lawson, Dumfries. *Foreign, any variety.*—First, J. Armstrong, S.C.A. (Love Birds). *Rarest Birds of any variety.*—Prize, J. M'Criric, S.C.A. (Cock of the North).

Judges.—*Poultry and Pigeons:* James Stevens, Esq., M.D., Ardrossan; Mr. James Paton, Stewarton. *Canaries and Foreign Birds:* Mr. G. Grant, Paisley; Mr. G. Crawford, Beith.

INCUBATOR MANAGEMENT.

I agree with your correspondent "Investigator" that it would be most useful if those interested in the artificial hatching of eggs would compare notes through your Journal. The subject is now being much inquired into, and I am satisfied it will not be long before artificial incubation can be adopted with the certainty of a successful and profitable result. I have for a considerable time devoted much attention to the subject, and the results of my experiments have been considered very satisfactory; but I cannot myself feel satisfied until with certainty I hatch every good egg that is placed in the incubator, and in a properly constructed machine this ought to be a certainty.

"Investigator" is mistaken in supposing that a temperature of 110° is fatal to the embryo life of chicks; this I know by actual experience. In August last I started my incubator towards evening, and finding about 10 P.M. the temperature had continued gradually rising until it had reached 110°, I lowered the gas to reduce the heat, but, as it turned out, not sufficiently, for on looking after it at 5 A.M. I found the thermometer still at 110°. I determined upon changing the eggs, thinking mischief had already been done, giving twelve of them to a broody hen, and leaving two in the incubator. The hen hatched eleven out of the twelve; the twelfth contained a dead matured chick. The incubator hatched one, the other being a clear egg. In other cases during my first trials I have frequently had the heat up to 110° in different stages of the hatching, and have found that if not continued too long it will not interfere with the actual hatching of the chicks. So great a heat ought, however, to be carefully avoided; one result that I have experienced from too high a temperature being that you will have a lot of chicks matured, and nearly so, dead in the shell; and another, that those which manage to escape from their shells, assisted or otherwise, will be extremely weak in their legs, growing worse as they become older, scuffling about more by the help of their wings than their legs, and most of them eventually dying.

I will conclude by naming what I am satisfied are essentially requisite in the artificial hatching of eggs—viz., damp atmosphere, otherwise numbers of chicks will die in the shell, and those hatched will be weakly; constant ventilation; temperature ranging from 100° to 106°, but as steady as possible at 103°—the heat to be slightly increased towards the end of the hatching; turning the eggs twice a-day; and darkness until the chicks are due, otherwise numbers will perforate the shell prematurely.

The incubator should also be placed in a room upon which the sun does not act, or it will be impossible to maintain a uniform temperature.—E. S.

THE EGYPTIAN BEE.—Part VII.

How I succeeded in transporting it to America.

Having, as related in page 306 of the last Volume of "our Journal," completely purged my apiary of an element which had turned out so entirely obnoxious, and having published without reservation the very discouraging results of my experience of the Egyptian bee, I had no idea that I should ever become possessed of the materials for another paper on the subject; such, however, turns out to be the case, and it came about in a rather unexpected manner.

During the latter half of September, I received a letter dated the 8th of the same month, from Mr. Jas. T. Langstroth, son of the distinguished American apiarian, and member of that eminent transatlantic firm, "L. L. Langstroth & Son, of Oxford, Butler County, Ohio, Importers and Breeders of Italian Queen Bees, and Agents for Langstroth's Patent Moveable Comb Hive." After very politely acknowledging and replying to a letter written by me last spring, and enclosing for my acceptance a *carte* of his distinguished parent, the reception of which, as will readily be believed, afforded me much pleasure, and which has formed a notable addition to my gallery of apiarian worthies, Mr. Langstroth, jun., went on to say—"We have been much interested in your articles in regard to the Egyptian bee, and, like true bee enthusiasts, are possessed with an insatiable longing for a queen of that variety. We would, therefore, ask you, as the highest favour you could bestow upon us, to forward us a pure queen of that variety, packed not like Herr Vogel's, but with sufficient honey for a twenty-five-days journey, and with rather *few* worker bees. For this queen we will remit you in draft on London any sum you see fit to name, on receipt of your letter advising us of her shipment. You will easily understand that we wish to have the credit of first introducing these bees to America, and to give you the credit of furnishing them for exportation to this country. We have only received the first four Numbers of The Journal of Horticulture, containing your description of these bees. If they do not mix with the natives or Italians as easily as the Italian race hybridise with the natives, and if they are less inclined to sting than the Ligurians, we shall hope that they may aid in the advancement of apiarian science in this country. If, however, *your* opinion (which we have not yet seen), is that they are 'a humbug' even, we still desire one queen for the purpose of experimenting. We, therefore, sincerely hope that you may be able to send us a queen, even if you have to replace her by the procurement of another from Herr Vogel, as we give you *carte blanche* in regard to price."

Reflecting on and admiring the facilities and wondrous speed of modern postal communication, by which the article announcing the successfulintroduction of the Egyptian bee into my apiary, and published in London so recently as the 21st of August, could reach one of the Western States of America so rapidly as to admit of its perusal, and a long letter being addressed to me in consequence within eighteen days, I debated how I could most speedily and completely fulfil the desires of my transatlantic friends. Evidently the first thing to be done was to "catch my queen," and as I had not one of the required species remaining in my apiary, I penned a few lines to Herr Vogel, on the 25th of September, asking him to send me another Egyptian queen as soon as possible, writing at the same time to Mr. Langstroth to report progress, and request farther instructions. Herr Vogel very politely acknowledged my note by return of post, informing me that he would dispatch a pure queen of this year on the 8th of October, and in due course I received from him the following, dated 9th of October—

"Dear Sir,—I have the pleasure of sending you a truly impregnated Egyptian queen, as advised in my last.

"The workers that accompany her are true Egyptian bees, and are bred by the queen you receive. She was reared about the end of July last, and all the queens reared from her brood turned out to be true Egyptians, the number being five.

"If there should be a few black bees among the workers that accompany her, they are not bred by the queen, but must have found their way into the Egyptian stock from a neighbouring hive.

"As the queen which you receive is unsurpassable in purity, I would suggest that in future you should rear your queens from her brood only, for then they will all be like the mother from whom they are descended."

This letter preceded by a day or two the arrival of the Egyptian queen, which came to hand on the 16th of October. She was packed this time in a small and light box, and reached me in much better condition than her predecessor, although both herself and her attendants were very torpid, and appeared benumbed with cold. I, therefore, lost no time in introducing her to a hybrid Italian stock from which I had previously removed the queen, and by which she was well received.

Prior to the arrival of the Egyptian queen, I had the following letter from the Rev. L. L. Langstroth, dated from New York, on the 28th of September, and in which he incidentally alludes to my controvery with Dr. Cumming:—

"Dear Sir,—I have been reading in the files of the London *Times*, to which I have just had access, your criticism of some of the statements of the Tunbridge Wells Bee-master. I had previously read his work called the '*Times* Bee-Master,' and the perusal of your communication, which under the circumstances must be considered as both courteous and forbearing, only deepens my conviction of his unfairness in controversy, as well as his ignorance on the subject he discusses. It would, however, be unreasonable to look for accuracy from a bee-keeper who not only describes an octagonal hive in use in his own apiary as a hexagonal hive, but who ascribes its great success to its hexagonal shape.

"Since writing to you from Washington, I have seen in Champollion's work on Egypt, figures of the queen, worker, and drone, of Apis fasciata. From my previous letters you will see how anxious I am to obtain this fall an Egyptian queen. As a matter of mere business, I can hardly expect to procure one of you this season, but venture to hope that you will 'strain a point' to put me in possession of so valued an acquisition. I have sent an order to Germany, but fear that it cannot be filled this fall. If you can send me a queen in whose purity you have confidence, I will defray any expense to you of procuring one next season, to replace her in your apiary. If under all the circumstances you can part with one, I would suggest sending her in one of your straw frame-hives, with plenty of provisions sealed over in old combs, and with a very moderate allowance of bees. The whole arranged for transportation *not à-la-mode* Herr Vogel. I have planned a simple and efficient contrivance for draining honeycombs on the centrifugal principle, as applied by Major Von Krashna. His happy idea will prove especially useful in some of our apiaries, where even under present arrangements a yield of from 100 lbs. to 200 lbs. of honey is often obtained from a single colony.—Yours very truly,

"L. L. Langstroth."

In compliance with these instructions, I packed the Egyptian queen and her alien subjects with the utmost care, in a straw frame-hive, and despatched them from my apiary to Liverpool on the 21st of October, thence to be sent on their long voyage across the vast Atlantic by the "Inman," line of steamships, one of which left England the next day.

The result was communicated to me by the Rev. L. L. Langstroth, in a letter dated from Philadelphia on the 15th of November, in which he says:—

"Thanks for your great kindness in the matter of the Egyptian queen. Thanks to your admirable packing, the colony arrived in perfect condition, and although not delivered to me until eight days after the steamer arrived, I found only a few dead bees—not many more, probably, than would have died had they remained on their stand in your apiary. A bee-expert at the Custom House pronounced the package to be the best conceived and executed of any he had ever seen. I should like much to pay you a deserved tribute in the columns of our bee-journals, but fear it would bring upon you an avalanche of inquiries from our excitable bee-keepers.

"I am not surprised that you found the Egyptians very cross in your cool and damp climate, for I find such weather as is the common rule with you makes the Italians quite irritable. Our dry and hot summers will, no doubt, seem natural to these daughters of the Nile."

I need hardly express my gratification at the complete success which has crowned my endeavours to transmit the Egyptian bee to the New World; and although I have myself very little hope or expectation that the extreme irascibility of this beautiful little Apis will become ameliorated by change of climate, it will, nevertheless, afford me much pleasure to learn that the favourable anticipations of my distinguished contemporary have proved more correct than the sombre vaticinations of—A Devonshire Bee-keeper.

P.S.—I may add that I presented my transatlantic friends with the bees which accompanied the queen, asking merely for repayment of my expenses out of pocket; a request which was most promptly complied with.

FOUL BROOD.

I now give my promised experience with foul brood. The stocks which I experimented with were eight in number: three which had had a part of their combs excised, and five

which had combs from diseased stocks. Two of those with excised combs and one of the others did not survive the winter, whilst another did well and swarmed twice. At this time I examined it, and found foul brood in the bottom box, while the two top boxes, which had old combs, were quite free, the disease having broken out in the new-made combs; but when the young queen commenced breeding it spread throughout the whole hive. In another I ventilated, and retarded breeding as much as possible, and it was only when the weather became warm that this one fell a prey to the disease. The other three stocks are quite free, and at this time the best I have in my apiary. I am inclined to think that the disease which causes foul brood exists in hives even when no breeding is going on, and that transferring diseased combs to other hives will infect them. Infected combs may be known by their clammy and adhesive character, and are of a brownish colour, appearing also thicker than usual, as if some fungus existed. I believe it is impossible to get rid of the disease so long as any of these combs remain; but I imagine that the side combs may be used with impunity if they have a fresh and dry appearance, as they were side combs only that were in the hives which escaped the malady, notwithstanding that the combs were taken from diseased stocks. My experience with foul brood leads me to believe, that instead of cold having anything to do with it, it is quite the reverse, and that it is warm weather which propagates it. This has certainly been the case in my apiary during the last two seasons.—A Lanarkshire Bee-keeper.

WOODBURY HIVES.

I will describe an improvement in the Woodbury bar-and-frame hive, especially where the compound bars and frames are used. I have tried it, and it quite answered my expectations. It is intended to facilitate the moving and removal of the frames, by doing away altogether with the notches in which the frames rest. In the front upper and inner edge of the hive you have, first the usual three-eighth rabbet; below this, instead of notches, is another rabbet one-eighth of an inch wide, by three-eighths deep, and the positions of the bars and frames are marked by incisions or lines, which are inked to make them more conspicuous. The back upper and inner edge of the hive has the rabbet made three-quarters of an inch deep; on this rabbet rests a loose piece of wood one-quarter of an inch thick, and three-quarters of an inch deep, by 14½ inches long. This piece is also marked with lines in the same way as the front of the hive, to show where the frames are to be. Through the back of the hive are five set screws which are made to bear on the loose piece of wood, so that when the bars and frames are in their places, by turning the screws the wood is pressed forward and holds them all tightly, so tightly, indeed, that the hive may be turned upside down, and drummed, without their getting out of their places. A bit of brass or iron is let into the moveable piece of wood where the screws bear upon it, to prevent its being galled.

I was led to this contrivance by the difficulty I have experienced in moving the frames when well cemented by the bees. The advantage of this plan is, that by loosening the back screws the frames are all set at liberty at once. The loose piece of wood can be easily pressed back, no matter how well cemented, and the frames can be gently pushed one towards another without lifting up, as you must do when they are in notches. Another advantage is, that old hives can be easily altered to this plan. It is also inexpensive, and the notched piece of wood at the bottom is never required to keep the frames in their places.

My experiments as yet have all been with the black bee, but I hope to have the opportunity of multiplying a stock of Ligurians next spring, and should like to ask Mr. Woodbury the way in which he would advise a bee-keeper to proceed with one Ligurian stock.

Can you tell me where the queen-cages (pipe-covers) described in Neighbour's book are to be obtained, and what is the price of them?—C. F. George.

[Wire pipe-covers are sold by many tobacconists at a very moderate cost, and form excellent queen-cages. Mr. Woodbury promises an article on the propagation of Ligurians at no very distant date.]

OUR LETTER BOX.

Address (*Rev. H. H.*).—If you enclose a stamped envelop your full direction we will send the address you ask for.

Rouen Ducks (*H. B.*).—If you read the report of the Birmingham Show you will see you were beaten in weight. Your birds of 1866, weighing 14 lbs. the pair, are, nevertheless, good birds, and would have won years ago. It is a good plan to confine them for a fortnight or three weeks before exhibition at a large show. Your feeding is good, and an increase in the amount of flesh will add weight. The great point in rearing birds that are intended to compete against all England is to feed them from the first with a view to success. By this we mean, never to allow them to become thin or out of condition. No amount of feeding will make winners of birds that have ever gone back. Indian corn is not good food for young growing poultry; it makes only fat.

Brahma Pootras (*Novice in Brahmas*).—There are certain points that are in dispute. Both sexes should have pea combs; yellow, feathered legs. The cock should have a black or spotted breast, we prefer the latter; and he should have a light hackle and saddle, black tail, and black-and-white-marked wing. The hen should be pencilled all over. For perfect specimens neither should have any buff feathers or shade. The hen should as much as possible be pencilled on the breast. Vulture hocks are objected to by many. Large size.

Crève Cœur's Head and Eyes Affected (*Crève Cœur*).—These birds are subject to such attacks as you mention when they change about from one place to another. We do not consider it infectious, and the convalescence is not long. While they are suffering they should have very little water. It is enough if they are allowed to drink three times per day. They should have no water within reach. Barley and oatmeal are the best food, with some whole Indian corn once in the course of the day. Buckwheat meal is good food for them, and that on which they are principally fed in France. Potatoes and pollard are not good. They must have green food; and if they have no grass run they should have good large sods of growing grass cut with plenty of earth—they will eat it all. It is not well to give them many peas. In such attacks you will find some stale bread soaked in strong ale very good food and beneficial.

Apportioning the Sexes in a Yard (*Lex*).—It depends on the time of year. At this season four or five hens are enough to run with one cock; but it is not necessary to carry this rule out strictly, as few hens are laying. As the weather becomes warmer the number may be increased to fourteen or fifteen. When you turn down another cock it is more than probable—almost certain—there will be fighting; but after it is decided which is the master they will take separate walks and hens. You can insure similarity of breed on one side by having all the cocks alike. We cannot tell you what the breed will be unless we knew the hens you keep. As a rule chickens take more after the hen than the cock.

Wart Under Hen's Eye (*J. H.*).—If it is productive of no inconvenience we should take no notice of it. If otherwise, it might be burnt with caustic; or if small at the roots it might be cut off.

Sprinkling Water on Incubating Eggs (*Harriet*).—The eggs require to be sprinkled with water once in the day (the morning is the best time), for ten days before hatching. If the weather is very frosty it should be done immediately before the hen goes on them after feeding. Half the failures in hatching are to be attributed to the neglect of this precaution. They do not want artificial heat, but at this season of the year they require to be in an outhouse sheltered from draughts, and the flooring of which is of earth and dust. They require high feeding, and it is well to give them a meal by candlelight at eight or nine o'clock, as the nights are so long. The chickens soon begin to look for it, and come out at the first glimmer of light. They should have beer to drink.

Comb of Cochin-China Cock (*W. H. G.*).—There is no fixed size for the comb of a Cochin-China cock. The essential points are that it shall be perfectly upright and correct in shape. We never saw a Dorking comb on a Cochin cock; their shapes are essentially different, and the Brahmas have pea combs, which are never seen on Cochins. Wherever the combs are overgrown they show signs of turning over behind, and such are disqualified. Most of the prizetakers at Birmingham have been successful exhibitors for years, and are themselves too good judges to send faulty birds.

Ladies' Pets (*A Lover of the Country*).—I see no reason why you should not indulge your desire for some Pigeons; and if you procure some of the tamer varieties, as Fantails, Trumpeters, Jacobins, Nuns, &c., they will not be likely to leave your place, especially if you have more than one pair. Of course, as pets you will provide them with comfortable board and lodging, and there is no reason to consider they would in any way prove a nuisance. A Jay may be kept tame in a cage and taught to talk, but Jays are very apt to be mischievous if allowed their liberty. Collared Turtle Doves would roost in your trees, and if tamed before they were let out would make very interesting pets. Bantams are very pretty, and would do well in your ornamental grounds; but if you fear them you might have Plovers if your grounds are enclosed.—B. P. Brent.

Goldfinch Mule with Indurated Skin (*H. Bedwell*).—I have examined the bird sent. I think rape seed injurious to cage birds from its pungency; but whether it would affect a bird in the manner yours is I cannot say. Round one eye, down the back of the neck, and along the shoulder of one wing, the skin is denuded of feathers, white, hard, dry, and granulated; at the back of the neck was a tumour of a white cheesy-looking substance as large as a pea. When living at Bessel's Green my fowls were mostly attacked in a similar manner, and Ducks would not live long with me. I attributed it to some mineral in the water, it having a greenish tinge, and the soil being what geologists call the green sand formation.—B. P. Brent.

POULTRY MARKET.—January 7.

We have had an anomalous week. There is always a temporary dearth after Christmas; but this year we have had snow enough to impede communications, and this has diminished our small supply. It has caused a rise that will not be maintained.

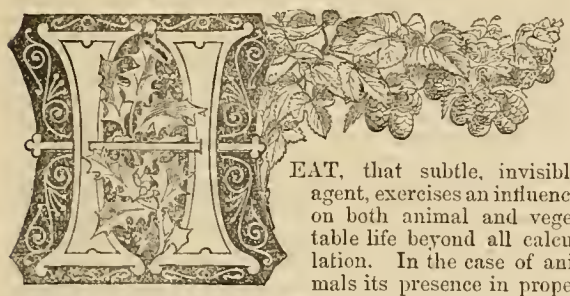
From observations taken near London during the last forty years, the average day temperature of the week is 42.3°; and its night temperature 30.9°. The greatest heat was 69°, on the 19th, 1828; and the lowest cold 4½° below zero, on the 19th, 1838. The greatest fall of rain was 0.88 inch. N.B.—The Calendar contains the names of plants flowering in the greenhouse.

MODES OF HEATING.



HEAT, that subtle, invisible agent, exercises an influence on both animal and vegetable life beyond all calculation. In the case of animals its presence in proper amount sustains life, and its absence causes death; while in the vegetable world it is scarcely of less importance, as growth is most rapid where it abounds, and the plants there attain grander dimensions than in colder climates. My remarks must, however, be restricted to the artificial means for the attainment of desired temperatures, the object being the supplying heat to a given space, whilst wasting as little as possible of the materials employed to impart that heat. Combustion of coal or other fuel is the source of such heat, although fermenting materials also supply it, and recourse to the latter mode of heating is not likely to be ever abandoned. I will, however, first advert to the mode of supplying heat by the combustion of fuel.

Let us now see how fire heat can be applied in the most economical manner. Assuming a given quantity of fuel to afford a certain amount of heat, in which way can that heat be used for the purpose required with the least possible waste? for, that a considerable amount of heat is wasted, even in the best constructed apparatus, cannot be denied. I have on former occasions argued that one of the best examples of fire being applied to an object from which it is again abstracted with the least loss, is afforded by an ordinary brick oven, where the combustion takes place inside, and the heated sides, bottom, and roof are all required for the purpose of baking bread; externally, I believe, but little heat escapes, and the amount of that which goes up the chimney is less than in many heated structures. This economy, however, is attained by the fire acting directly in accomplishing the object in view, and not by its heat being communicated through another medium, as in the case of plant-houses; for in the latter it is the atmosphere that requires warming, and it is difficult to apply fire heat by any very direct means without at the same time imparting to the air some properties injurious to vegetation. Heat, however, has sometimes been applied in a manner more direct than is often thought practicable, but the results have not generally been satisfactory. A mode of doing so, however, which came to my knowledge many years ago is worth repeating, as it was one of the most remarkable cases of fire directly supplying bottom heat that I am acquainted with. It was as follows:—

In the coal districts of the north, before the demand was so great for small coals for steam-engines and other purposes, large quantities were thrown away as waste at the mouth of the pit, and being ignited, and augmented daily by several tons of additional fuel, an immense fiery heap was always burning at the mouth of the pit. I believe some of the heaps covered an acre of ground, and a red and lurid flame might be seen miles off on dark evenings. Some of the heaps were 20 or 30 feet deep, the outer edge sloping off to meet the natural ground, and it was on the outer edge of one of these fiery heaps that some one attempted the out-door forcing of vegetables. As the fire had in a certain measure left the corner he intended to operate upon, although the ashes were still hot below, the operator determined to cover a portion of the heap with earth, and plant Potatoes, which he watered and attended to in the proper manner; and as at a local horticultural show prizes were offered for the best dish of Potatoes grown in the open air, his crop was deemed eligible, and he easily carried off the first prize. Here, then, was a case of the direct action of fire underneath the object forwarded. Although it is not an example which it would be prudent to imitate, some modification of it might be attempted; and the mode adopted at Leeds Castle by C. W. Martin, Esq., M.P., as detailed in the last Volume, is one of the methods in which heat from beneath may be applied. This plan, as will be remembered, was by having an underground chamber, at one corner or side of which a fire was kept, which, playing all over the chamber, was not allowed to ascend the chimney until all the heat had been expended, and the little smoke unconsumed rendered comparatively cool. This Mr. Martin calls the hypocaust mode of heating, and its merits are its simplicity and the ease with which the heat acts on the part where it is most needed, which is, of course, the roof.

In this immediate district, where large quantities of Hops are grown, the drying them by fire heat has called forth many modes of applying it, from some of which hints may, perhaps, be gleaned. Hops are more frequently gathered wet than dry, and even if they were always dry they would have to undergo a process of fire-drying in order that they might be kept without moulding, for the moisture in the stalks and bases of the scales has to be driven out by heat, and this is an operation involving a large expenditure of fuel. Such, too, in the general construction of Hop-kilns is of a rather expensive kind, ordinary wood and coal fires being seldom used, although in one of the cases where this is done the plan so closely resembles what is called the Polmaise system that it is worth describing here. I may in the first place remark that Hops are generally dried on a floor up-stairs; the floor, instead of being of the ordinary description, is composed of a hair-cloth spread over a latticework of timber not likely to ignite with the heat, Poplar wood being esteemed the best. Very often the kiln is circular, and from 12 to 18 feet in diameter; the chamber, where the fire is burning, is seldom less than 12 feet, and more frequently 15 or 18 feet, high to the drying floor, and the roof tapers up in a conical manner from a little way above this floor to the apex, where an opening, 3 feet in diameter, is left for the steam to escape. This opening is protected from rain by a cowl moving with the wind, and every care is taken to insure the steam passing off quickly. The interior is plastered

smooth, and the latticework is close enough to allow of a person walking over it in safety, the woodwork occupying about one-half of the area. On this floor, to which access is gained by a door, green or wet Hops are often laid quite a foot thick, and the moisture they contain is driven off in about ten or twelve hours, seldom more than the latter, as such kilns are kept going night and day, and two loadings in the twenty-four hours are expected. Allowing a little for loss of time in putting on and taking off the Hops, ten hours may be said to be required in drying a mass quite a foot deep by means of the fire kept on below, the heat passing up through the coarse hair-cloth and through the mass of Hops lying upon it.

One of the modes of applying fire heat to dry the Hops is by means of what is called the cockle system, being simply a cast-iron box of about a cubic yard in capacity, which is turned bottom upwards inside the heating chamber, and has the fire underneath it. There is in one side of the box a very small hole for the escape of the smoke, which afterwards traverses a flue passing round the chamber, and finally enters a chimney. There are dampers at proper places to check the fire burning too briskly. The heated metal, the fire being inside, or rather underneath the box, gives off the heat that dries the Hops, and cold air is admitted from the outside, and passes over the top of the cockle. This mode, as will be seen, resembles in a great measure the Polmaise system, and I need hardly remark that any kind of fuel is available for such a heating contrivance; it has, however, all but gone out of use for Hop-drying, few kilns being now erected on this principle, and in most of the older ones open fires have been introduced. In their case the fireplace is raised a little in the middle of the heating chamber, and merely consists of bars a foot or so from the ground with a little brickwork surrounding them, and for about a foot higher. Directly over the fire, and about halfway between it and the drying floor, an iron plate, about 4 feet square, is hung by a chain to the kiln floor; this, receiving the upward current of heat, spreads it all around, and at the same time prevents any danger of the centre of the floor taking fire. Coke, charcoal, and Welsh coals are burnt—not common coal or wood, as the smoke from either would be objectionable.

The heated air from the fireplace in passing through the mass of wet Hops dries them by degrees from the bottom to the top; and to encourage a stronger upward current of hot air various means have been adopted. With this view openings in the outer wall at the bottom are general, sliding shutters being provided to close them when required. A few years ago a patent was taken out for a plan in which a number of cast-iron pipes were carried in a slanting direction from the bottom of the outer wall to the top of the fire. The pipes lying in this position, and their ends being open, it was considered that the heat acting on the upper ends of the pipes would cause the air which these contained to ascend, and that its place would be taken by air from the outside, entering by the lower end. This plan had many advocates for a time, and the principle was highly spoken of as affording a certainty of a greater volume of heated air being driven upwards than by the means previously in use; but these advantages seem to have been more imaginary than real, for during the last year or two the plan has in many cases been abandoned, and the simple method of allowing an open fire to collect its own air to heat and send forth in the best manner it can has been again resorted to as the most simple and effective means of drying Hops. Colling's patent, as the invention alluded to is called, has, therefore, fallen to a considerable extent into disuse.—J. Ronson.

(To be continued.)

ADMITTING AIR TO VINES.

In a recent communication I made a few remarks, founded on experience, on the formation of Vine borders. I will now advert to a subject which is of as much importance in connection with Vine-growing, and that is ventilation. It has been ably discussed in The Journal of Horticulture already, but the more it is brought into prominence the more will its importance be appreciated, by young gardeners especially.

As soon as Vines commence growing in the spring they make rapid progress, and require unwearied attention until the Grapes are perfectly ripened and perfect in flavour. If the latter are not both there must be something wrong, and no cultivator ought to be satisfied until he arrive at some definite conclusion as to the reason of it. If the evil is in the borders no amount of attention to ventilation can remedy that; but if the borders are not in fault, perhaps the ventilation may have something to do with it. To be successful in anything requires a great amount of patience and careful attention to the most minute particulars; but more especially is this the case in gardening. A quarter of an hour's inattention in the early months of the year will do more mischief than can be remedied in the course of the season. It is in the early months of the year that the gardener must be watchful, and especially so in regard to Vines. Judicious ventilation is of the utmost importance to them.

When vineries are of the lean-to description it is seldom that there is any means of ventilation provided in the back wall of the house. Now I think this is a mistake. In wet weather the lights cannot be drawn down, and the front sashes must be opened instead; but if means of ventilation had been provided in the back wall it would have been better to have afforded a little air there. I have gone into a vinery in a dull drizzly day, and it was easy to perceive by the closeness of the atmosphere that none of the ventilators were open. The lights had been drawn up on account of the rain, and the person in charge did not think it of consequence to open the front sashes. Now, if ventilation had been provided in the back wall, and the ventilators had been opened a little in dull weather, it would have kept the atmosphere pure without materially lowering the temperature. In a house 30 feet long, four spaces 18 inches long and 6 inches wide would be sufficient, with a board in each to hang on centres, and all to open at once with a rod and lever. If a fine wire netting be fixed over the outside it will prevent the ingress of all insects, check the force of cold currents of air, and still admit enough in dull weather.

I have often experienced the benefit of opening the ventilators a little very early in the morning. I like to take advantage of that period of the day to thin the Grapes before the sun rises high and becomes troublesome. I put on a little air before commencing operations, at the highest point of the house generally, by drawing down every alternate light about 2 or 3 inches, and by this means the atmosphere is insensibly changed, and no oppressiveness is felt, which certainly is the case when no air is admitted. As the sun rises the thermometer will also rise rapidly, and more air must be admitted; but a watch must be kept for the cold cutting winds which are so prevalent in the spring months, for the berries are sometimes injured by cold draughts, especially in their young state, while the foliage is apparently unaffected.

There is also much to be gained by judiciously husbanding the sun heat, especially by shutting up early in the afternoon. I think it well, also, to have the hot-water pipes or flue at nearly a uniform heat, excepting, indeed, in very severe weather, when the temperature of the house must not be too low. I would rather see in a cold frosty night the temperature 5° lower than usual, than the pipes overheated to raise it to the required point. In many cases enough pipes are not put in at first; and for the sake of an extra first expense an ultimate loss is incurred, more fuel is wanted, and the plants are liable to be injured by the fumes from overheated pipes. In a house 16 feet wide there ought to be six rows of four-inch pipes—that is, if the Vines are to be forced early, as half of that heating surface would keep the frost out if the Vines are only intended to start naturally, without the aid of heat artificially supplied.

I may also allude to a circumstance connected with some young Vines planted here in the spring of 1864. It happened that with some of the sorts to be planted I was unacquainted, and if on bearing they were found to be unsuitable they were to be removed. Some of the others were not intended to be permanent; so that by planting a permanent Vine between those which were not to remain I could in the second season train a young rod up from each side of the permanent Vines, to be ready to take their places in the autumn of 1865, when the first crop was cut. I found that where two rods were trained up in that way the main or central rod was stronger than in the case of the Vines which had only one rod, and I believe it had as many roots as any two of them. If I had the opportunity I would like to plant a vinery, say with room for nine Vines 3 feet apart, in this way—

. . . . . .
2 1 2 2 1 2 2 1 2

I representing the permanent Vines not to be cropped the first season; 2, those to be cropped heavily in the second season and then to be destroyed, while two young shoots must be trained up from each of the permanent Vines to supply their places. Thus there would be six Vines to bear a crop the second season after planting, each of which would carry from

9 to 12 bunches. In the third season after planting the permanent Vines would be able to carry a crop of twelve bunches each. They would, I have no doubt, support double that number; but it is better to crop lightly at first, as the young rods will have to make wood that season.—J. Douglas.

NOTES ON SOME VARIETIES OF THE POTATO.

As planting time is approaching, in fact come, to those who have warm nooks and corners, allow me to state my experience of some of the leading kinds. Being located in one of the best Potato-producing districts, with a soil that can hardly be surpassed for producing them to perfection, I have thus had an opportunity of growing, seeing, and proving many kinds under favourable auspices; and I have paid attention to the subject for nearly half a century, collecting materials, very heterogeneous I must say, on the management, cause of disease, and preventives, enough to supply an editor with clippings and anecdotes for several years; but as the cattle and Potato plagues have alike set all our knowledge and writing at defiance, and proved one nostrum after another useless, I shall not vex you with extracts from my Potato *bibliothèque*, but give a list of sorts and their qualities as proved here (Somersetshire), on a fine, deep, sandy loam—a soil never too wet nor too dry.

1. *White Clumper* first, as being our great staple production here, and a sort that resists the disease better than any other kind that I have tried. The crops of it have been extra fine this season; and I have heard the growers say, that although they lost one-third by the disease, yet they had a good average crop left. This kind also keeps well until late in spring, or, in fact, till the early kinds come in. It is a good-flavoured sort, and boils dry, but having a yellowish tinge when cooked it does not look so well at table.

2. *Grammar.*—A red Potato, very like a Fortyfold, a great cropper, and was cultivated largely at one time in this neighbourhood, but having proved watery in the heart when cooked, it has been abandoned. I think this is the sort called Grampart about London.

3. *Fortyfold Early.*—Our best early and best second early sort; white, mealy, and nicely flavoured. It requires a rich soil to grow it to perfection. It is, *par excellence*, my favourite Potato. When the size of a marble you can cook it, and it will prove dry from beginning to end. It is rather subject to disease.

4. *Fortyfold Late.*—Exactly like the Early in colour, quality, and flavour, but is the best late-keeping sort I know. It is very subject to disease, on account of growing so late in the season. Perhaps the same as Covent Garden Blue.

5. *York Regent* is unsurpassed for dryness and other qualities. It comes in early, keeps late, and is fine all the year round. The Dalmahoy planted alongside of it proved to be the same. The seed was procured from Messrs. Lawson and Son, who sent it out under the new name. The seed had been evidently grown in that fine Potato district that lies between Musselburgh and Dunbar, on the Firth of Forth. They looked a fine improvement on the Regent, but cultivated together I could see no difference.

6. *Patterson's Victoria.*—This has proved here to be one of our best kinds, and apparently an improved Regent of a flatter form, more like a Lapstone. It is mealy and excellent, finely flavoured, and a great cropper. It grows late, and is therefore subject to the disease; one-third of mine perished. This is just the sort for "Solanum," it grins through its leathery jacket in fine style.

7. *Fluke.*—Now so well known that description is useless. Its thready appearance when dressed is its only fault.

8. *Mona's Pride* is an early sort any one might be proud of having raised. Early, prolific, dry, and of fine flavour, I think it the best of the Ashleaf family.

9 and 10. *Salmon Kidney* and *Red Ashleaf* have been here famous croppers, but only second-rate in quality.

11 and 12. *Royal Ashleaf* and *Imperial Ashleaf* are two wortbless sorts when compared with others; the names are the only thing either Royal or Imperial about them.

13 and 14. *Telegraph* and *President* are very good pig Potatoes, and, like 11 and 12, the names are their best recommendation.

15. *Myatt's Prolific.*—A first-rate second early, mealy, and finely flavoured. Produces good crops.

16. *Napoleon.*—A fine mealy Potato, fit for a Prince's table.

17 and 18. *Dean's Early Ashleaf* and *Dean's Royal Prolific* seem very good, but I have not seen enough of them yet.

19 and 20. *Patterson's Blue Round* and *Seedling Rock* are both so like others—viz., Jersey Blue and White Rock, that I cannot see any difference. The last is, however, a fine Potato, and does remarkably well in this locality.

21. *Handsworth Prolific.*—The most dwarf Potato I know, and the earliest. If its other qualities were equal to those, it would be first-rate as an early sort. It might be improved with Early Fortyfold.

22. *Oxford Early.*—This is designated by one of your advertising friends as "the best Potato out," and I endorse the opinion so far as to say that it is one of the earliest, one of the dwarfest, and one of the handsomest of its race; it is also mealy, but yellow-fleshed—a great drawback with many people who prefer showy, laughing, mealy kinds, as "Solanum" says, tempting you to eat them.

I have stated my experience with a few kinds that I have tried here from time to time, and described the kind of soil they were tried upon. "D.," of Deal, would have added increased value to his article, page 462-3, Vol. XI., had he told us the sort of soil his is, which I suppose is a good one, being near the sea.—J. Scott.

P.S.—On the morning of the 3rd, thermometer at 17°; 4th, thermometer at 12°; 5th, thermometer at 10°. Snow 6 inches. One o'clock, thaw going on fast.

GARDENERS' EXAMINATION FOR HONOURS.

We are now enabled to give the list of the successful candidates at the recent examinations of the Royal Horticultural Society, and it is very encouraging to see so many of the young men who presented themselves come off so well as they have done. Although this is the first examination of the kind the Society has held, it shows how large a per-centage of the young gardeners of the present day really devote their time to the acquirement of a thorough knowledge of their profession; and it is also evidence against an opinion, which was becoming somewhat general, that the young gardeners of the rising generation had no aspirations, and that the race of the Paxtons, Spencers, and Thomsons was rapidly becoming extinct. We are informed, judging from the papers sent in, all of which were more or less highly creditable, that if these examinations become permanent, we may look forward in future years to having a much larger number of educated and high-class gardeners in the country than we have ever had, and we shall know also where these are to be found. We hear, also, that even those who failed on this occasion gave such evidence of better things as to leave no doubt of their success on a future occasion.

The Council of the Royal Horticultural Society, on the report of the Examiners, elected, on the 8th inst., Mr. R. C. Kingston, Royal Gardens, Kew, and Mr. George Stanton, Berry Hill Gardens, Taplow, Maidenhead, to be Associate Members of the Society. A medal has also been awarded to Mr. G. Stanton for the highest number of marks in practical gardening.

The following certificates have also been granted—viz.:

		Floriculture.	Fruit and Vegetable Culture.
Geo. M. Woodrow, Royal Gardens, Kew		1st-class certificate	
Alex. Robinson	Chiswick Students.	2nd-class certificate	2nd-class certificate
William Spinks	Chiswick Students.	1st-class certificate	1st-class certificate
Brian Wynne	Chiswick Students.	2nd-class certificate	
Thomas Wright	Chiswick Students.	1st-class certificate	2nd-class certificate
Henry Hannan	Chiswick Students.	1st-class certificate	2nd-class certificate
John M. Henry, Royal Gardens, Kew		2nd-class certificate	2nd-class certificate
Fredk. Thompson, Royal Gardens, Kew		1st-class certificate	2nd-class certificate
A Jamieson, Royal Gardens, Kew		1st-class certificate	
John Stapley, Hovenden, Biddenden, Staplehurst.		1st-class certificate	2nd-class certificate
Thomas Waddington, Millfield House Gardens, Cobham		1st-class certificate	2nd-class certificate

Gardeners' Improvement Societies.—Any of the Gardeners' Mutual Improvement Societies who have joined the Royal Horticultural Society, will oblige by sending to The Journal of Horticulture copies of their rules and by-laws for the guidance of young societies.—Taplow.

VINES AND VINE BORDERS.

I THINK Mr. Wills has entirely misunderstood my motive in asking for further details respecting the Vine borders at Huntroyde. It is not often that any gardener has the opportunity of doing what Mr. Wills proposes to do, and having begun the culture of the Vine on a large scale without any practical knowledge of the subject, I thought Mr. Wills would be able to say whether I ought to be satisfied with the growths my Vines have made, or whether I could have doubled their growth if I had gone to greater expense in forming my borders.

In the account I gave of my Vines (page 421), I omitted to say that I allowed many of them to bear from one to three bunches each. Where three were left two were on side shoots, and the other on the main shoot. These bunches were well coloured and ripe in the early part of September, four months from the date of planting.

If Mr. Wills had followed my example, and given a fair statement of the cost of the proposed Vine borders, including brickwork, flags, hot water, air-shafts, &c., I should have been much obliged to him; and I can see no reason why my desire to know more about these Huntroyde Vine borders, which, when completed, will contain nearly 3000 cubic yards of compost, should induce him to regard me as a foe or a grumbler.

That the compost described by Mr. Wills will grow very good Grapes I have no doubt, from the fact that the Vine grows vigorously in all soils and in all countries, from the shores of the Baltic to the Peak of Teneriffe; in the strongest clay, as well as the poorest of sandy and gravelly soils. The finest young Vines I ever saw were growing in ordinary garden soil a few miles from Tirlemont in Belgium. The valley of the Garonne has no advantage in soil over the valley of the Medway. Will Mr. Wills say why Maidstone has not its vineyards as well as Bordeaux? If luxuriance of vegetation depends more on soil than climate, why should not the Castor-oil Plant be grown in England as well as in Italy, or the Sweet Chestnut ripen its fruit in our woods as well as it does in the south of France.

I assure Mr. Wills that having made a section of his borders in accordance with the description given in his article of the 16th of October, I am not likely to forget anything about them, and I am only waiting for the particulars as to cost which I have asked for to complete my notes for future reference.

Notwithstanding Mr. Wills's explanation about the nine-inch layers of his border, I am still unable to see what benefit 336 pecks of soil will derive from 1 peck of bones. "The expense is not so great to gentlemen." I am surprised that a writer of the Journal should forget that many hundreds of its readers are gentlemen without "a piece of land from which the sods can be cut," and whose purses are unequal to the demand of "ten guineas a-ton" for bones. I shall always be ready to exchange information with Mr. Wills, either about Vines or the soil and climate proper to grow them in, but only so long as he is disposed to discuss the matter in friendliness and candour.

Would Mr. Wills really be so very much astonished to see an "article by Mr. Thomson, or any other gardener endowed with a moderate share of common sense, advocating such a barbarous system of Vine culture" as that mentioned by your correspondent "VITIS?" If so, why has he not already given utterance to his indignation at the barbarity of shutting up a Vine in the mid-season of its growth in a mean temperature of 81° for Hamburghs, and 85° for Muscats? Mr. Wills must surely know that this temperature, in which the "proprietors of villa residences who are not supposed to employ scientific gardeners" are recommended to grow them, is wholly unnecessary. Is Mr. Wills's silence to be attributed to the benefit he has received from the application of the author's styptic to the bottoms of his Pelargonium cuttings?

If we were to follow the 45th degree of south latitude from the coast of the Bay of Biscay, making little excursions for a few degrees north and south of that line till we come to Astrachan or the Caspian Sea, we should pass through countries possessing great diversity of soil, but almost equal summer temperatures, and nearly the same annual rainfall. In these countries, with 23 to 27 inches of rain annually, and a mean summer temperature of 70° to 73° Fahrenheit, the Vine grows and fruits well even without cultivation. In Mr. Thomson's treatise it is recommended, "By the time the bunches are in bloom" to "let the night heat be 70°," to allow a rise by sun heat to 80°, and to shut the lights early enough to raise the thermometer to 90°. In growing Muscats it will be right to increase these temperatures 5°. Does Mr. Wills know of any country where Vines have to endure a like heat at the period of their bloom? Is he aware of the rainfall necessary to countries having so high a temperature? The lower valley of the Niger has a temperature in the beginning of the rainy season of 74° to 80°, rising in the month of September, as the rains decrease, to from 76° to 84°. The annual rainfall is from 6 to 7 feet, and this is more than doubled by the river, which in its rise of 28 feet in perpendicular height brings down an immense volume of water at a temperature of 80°, producing a luxuriance of vegetation never seen in the home of the Vine, but which delighted the sight of your correspondent "A SURGEON" in his visit to the home of the Oil Palm. The Vine seems to be very much at home in the lower valley of the Volga. The rainfall and the temperature during the summer months are about the same as in the south of France, the heat perhaps a little higher, and the Grapes as fine as any in the world. The mean summer temperature is 72°.

I do not say that Mr. Wills will not do very well with his borders. I believe Mr. Thomsen has grown good Grapes in the heat he recommends; but I do say the heat of the one and the soil or compost of the other are wholly unnecessary for the growth of Vines. I hope in time to be able to prove they are equally unnecessary for the growth of Grapes.—H. S.

PSIDIUMS.

IN answer to your correspondent "G. S.," Psidium Raddii requires a stove to bring it to perfection, it is then superior to P. Cattleyanum. I am under an impression that "G. S." has not P. Raddii, as I am not aware any nurseryman has it true in this country. "G. S." states, "There are two varieties of P. Cattleyanum, the fruit of one being spherical, and the other somewhat Pear-shaped." This assertion shows how careful people should be before they make a positive statement; for the one is P. Cattleyanum, which attains a height of from 15 to 20 feet; the other, P. chinense, which averages from 6 to 8 feet. They are equally hardy, and great bearers.

Psidiums as yet have not had that attention paid them they deserve, as they are equally useful at the dessert and for jelly; and it must be borne in mind that those which appear least grateful to the palate make the best jelly.

The Psidiums which I cultivate are—1, P. chinense; 2, P. dichotoma; 3, P. aromaticum; 4, P. acre; 5, P. pomiferum; 6, P. Raddii; 7, P. pyriferum; 8, P. Cattleyanum; 9. P. montanum; 10, P. cuneatum; 11, P. araça; 12, P. araçaçaçean; 13, P. sp., a large purple kind. Nos. 11 and 12 are Portuguese names, and very distinct. I consider the best four of the above to be—1st, P. araçaçaçean; 2nd, P. Raddii; 3rd, P. pyriferum; 4th, P. aromaticum; but all are useful, as they come in at various times.

I imported the above, as no dependance is to be placed on purchasing them true, even if they can be obtained at all.

CASIMIROA EDULIS.—I see the above-named plant advertised by a London nurseryman, giving a flaming account of its capabilities of adapting itself to various situations. It may exist in the west of England in a sheltered situation, but it requires a stove to grow it in perfection, when it becomes a large bush, having numerous Apple-shaped fruit. The fruit are very palatable, and liked by some, but must be used with caution, as they are liable to produce lethargy, which lasts some time, and is difficult to shake off.—RADDII, *Peterborough*.

THE CHANNEL ISLANDS' FIG.

I AM obliged to "G. S." for recalling this matter to my mind. There is no doubt whatever that he is right in stating that the common Channel Islands' Fig, so largely exported of late years, is not identical with the Brown Turkey Fig. I consider our Fig by far the finer, and the more valuable of the two, and it might be worth while for English market-growers and others to cultivate this sort more extensively. It has been known in these Islands for a very long period, and I should like to know when it was first introduced at Tarring, as it is cultivated there at present, and under what form of training and pruning it thrives at that place.

For my own part I believe that if the Fig tree be not closely summer-stopped, it would be best to leave it unpruned altogether, cutting clean out any useless shoots. Here the growers spread it out over a low platform of poles, and thus expose a large surface to the vertical rays of the sun. Many young

shoots, of course, assume a vertical position, but the crops are so enormous that they prevent any gross production of wood. Nothing is done but thinning out these verticals. Of course nothing grows underneath the tree, but then this causes the soil to remain unmoved—an essential matter with most fruit trees.

In seeking to identify the Channel Islands' Fig with the Brunswick, Turkey, De l'Archipel, or that capital sort Black Genoa, I sometimes thought the last identical with ours, but the ultimate decision must rest with Dr. Hogg. Let any one read through the chapter on Figs in the "Fruit Manual," and he will be possessed with increased respect for the care which has produced it.

It was with pleasure that I saw "G. S." had turned his attention to this matter; but why call our Fig the "Common Purple?" Why not "Channel Islands' Fig," considering its antiquity and increasing culture? May I, in the name of many here expectant, request a verdict?—T. Bréhaut, *Guernsey.*

STRATIFIED VINE BORDERS.

In page 22 your correspondent "A Gardener" considers it "exceedingly presumptuous" in me to offer any remarks on Mr. Wills's system of making Vine borders. Alas! poor me, and "J. S." and "H. S.!" what assurance we must possess to approach a subject treated on by a Jupiter! for evidently Mr. Wills, although I am sure entirely innocent of it, is so considered by "A Gardener." I saw and described a vinery and a Vine border, both of which I thought of high excellence and great simplicity. If your correspondent had also gone, and had exercised his eyes and his reason, he could have enlightened us as to any defects in the Bishop Stortford system. My motive for writing the article was that I hoped it would awaken some of our clever gardeners as to the feasibility of making Vine borders as Mr. Miller has done; in fact, I wished to know the opinion of some clever observer as to the merits and demerits of the system. I described as well as I could what I saw. "A Gardener" merely gives us his opinions; one of them I know to be fallacious: "The roots of the Vines (in an inside border), would go down not only many feet, but yards." Now, I know from long experience that the roots of Vines are most easily kept to the surface if they have annually surface-dressings. In a very sensible article (page 7), by Mr. J. Douglas, I am supported in my views on this subject.

Why the roots of Vines planted in a border inside should the second season find their way through the floor to a depth of 9 feet, as described by "A Gardener," is something very remarkable; there must have been something wrong at the surface. I know this is "presumptuous" on my part, but I can only refer to Mr. Miller's border, which I have no doubt will be copied by hundreds, who will not dread being "led sadly astray," as your correspondent fears. The truth is, what has been done and found good will be imitated; and so sound knowledge spreads, in spite of clever and fluent writers, which but few of us gardeners are; still, what we know we should endeavour to make known, however homely the style.

There are many good things in Mr. Wills's articles, but his stratification I cannot understand—a homogeneous border seems so much more in accordance with Nature and common sense. How Mr. Wills can command the roots of his Vines to finish the food in one layer before they seek it in another (see page 479), I am, I confess, entirely at a loss to conceive. To say to roots, "This is your food for 1867, in 1868 you may take the next layer," is something perfectly new. If they were sentient beings, and could understand the word of command, all would be well; but roots are eccentric, as described by "A Gardener," and I have no doubt would refuse to obey the dictum of even our most clever Grape-grower, Mr. W. Thomson, whose book all should read. The only method I have found fully successful in commanding the roots of Vines is by light, rich, summer-dressings, so that in the course of the summer the surface of the borders and the pots in which my Vines are grown is a perfect network of roots all running to be fed. This, not only with Vines, but with all other fruit trees, is the most perfect of all modes of culture; it is practised most undoubtedly by our good gardeners, but as yet not nearly so much known as so valuable and simple a mode of culture ought to be. "The million" ought to know that the surface of a fruit-tree border, or the surface round an isolated fruit tree, should never be stirred more than from 1 to 2 inches in depth, and only then if the soil be stiff and inclined to "bake" in summer, and that it should have annually in April a rich light dressing from 1 to 2 inches in depth. This opinion, I fear, your correspondent "A Gardener" will think "presumptuous." So be it.

In writing and thinking about inside borders for Vines, it has occurred to me that Grapes, Melons, and Cucumbers are all natives of climates very different to ours. There, Grapes ripen freely in the fields and hedges; there, the Melon and Cucumber are equally at home. Now, we should think a gardener a very original cultivator if he planted his Melons in the cold soil outside his Melon-frame, and trained the young fruit-bearing shoots under the glass; he would have to whistle for his Melons. It is true that the lignceous Vine roots bear the cold and moisture better than those of the Melon; but the reasoning for outside-border-making for Vines rests the same; it is, in fact, perfectly illogical in theory and practice.

In his second paragraph "A Gardener" seems to think I am poor and ignorant, and that I ought to have humbly written to Mr. Wills for advice under my peculiar circumstances. I fear I must sport a piece of brag. My experience dates long before that of Mr. Wills, and my purse is strong enough to allow me to spend £1000 on a Vine border without inconvenience if I felt inclined.—Vitis.

ARE AUCUBA BERRIES POISONOUS?

During the late severe frost I allowed two robins to live in my large greenhouse, where I have two Aucubas with ripe fruit. My attention has just been turned to the beautiful berries, and I found something had eaten off the pulp from the seed, and wondered what it could be. I thought a mouse had taken the brilliant morsel; but, on inquiry, my young men had found one robin dead in the path, and a post-mortem examination proved that it had been poisoned by eating the berries of the Aucuba japonica.

It is well that the greatest care should be taken to keep these most beautiful and brilliant berries from children or inexperienced persons—so tempting, yet so fatal. Being at present but little seen or known, yet likely to be produced on one of our most general, most attractive, and ornamental shrubs, it is necessary to promulgate this caution, to prevent, if possible further more unhappy results.—Jabez J. Chater, *Gonville Nurseries, Cambridge.*

[This is a timely note of warning; but it is not quite proven that the berries are poisonous. What became of the other robin? Might not the cold, or fighting, for robins are most pugnacious, have killed that found on the path? It is very desirable to give some of the berries to other birds and animals which will eat them, and thus prove whether they are poisonous.—Eds.]

EFFECTS OF THE INTENSE COLD.

As you invite your subscribers to let their experience be known through your Journal, I venture to speak of mine during the late intense cold.

I live on Earlswood Common, Redhill, thoroughly exposed to the south and south-west, partially sheltered from the north and east, situated on the clay, and lying low.

I have a good many Laurels, and upwards of 250 trees of the best varieties of Roses. The thermometer on the 3rd was at 4° about 12.30 A.M. It sank much lower I believe, but I did not register it, though I know it was below zero at a friend's in the neighbourhood. This is the result: Laurels are all bronzed, though not killed outright. Roses are all right, except Pavillon de Pregny, which seems much put out by the frost. Madame Furtado, supposed to be tender, I believe to be very comfortable and unharmed; Rushton Radclyffe as well as any. Isabella Gray and Maréchal Niel (mother and child), grow in the south side by side. Isabella is much cast down, and looks wrinkled and aged; Maréchal Niel looks as well as he can possibly do; and yet both were unprotected, except by a little litter at the roots. The trees are all newly planted. Moiret, Comte de Paris, Devoniensis, Homère, Du Luxembourg, Louise de Savoie, and Narcisse, all against the house facing the south, seem happy and well-to-do enough. At this I cannot but rejoice, as I was reared in the belief that Teas cannot stand 32° of frost. Of course I cannot say whether their blooming will be affected, but if this depends on the condition and appearance of the wood at present, I do not think they will disappoint me. I can let you know this if you care that I should. I shall hope to see

the experience of others in the next Number of the Journal. —A. B. A.

[We shall be much obliged by the future notes you offer; and we shall also be obliged by notes from other correspondents on the effects of the intense cold.—Eds.]

NOTES OF AND ABOUT ROSES.

(*Continued from page* 3.)

3. French Roses with English Names.—When a French grower obtains a good Rose from his seed-plots, which, according to his own estimate of it, he describes as "*Variété extra, superbe, très belle, remarquable, hors ligne*," &c., it is, of course, offered for sale as soon as a stock of it has been propagated; but it is too often the case that others inferior to it in all points, and therefore not desirable, are sent out with it, coupled with the flattering but deceptive descriptions for which the French language affords great facilities. This is an especial failing of an eminent Paris nurseryman, which cannot be otherwise than detrimental to his reputation; for although we are indebted to him for some of the best Roses in cultivation, his best productions have been, for some years past, invariably accompanied with others that have proved worthless and disappointing. There is an old French proverb which runs thus—"*On voit d'un autre œil que ne voit son prochain.*" If we loosely interpret this to mean "Each one takes his own view of the matter," and accept it as a truism, we must make allowance accordingly; but there remain some obstinate facts, such as were shown in the previous communication.

Many of these inferior kinds have English names attached to them; they are, therefore, sure to attract attention in this country. There can be no wish to depreciate the *politesse* of our French friends; we readily acknowledge the distinction they pride themselves on, of being the most polite people in the world; but can we receive with a good grace compliments that have a tinge of the ridiculous, and, as intimated by one of our oldest rosarians, accompanied with an "*arrière pensée*," connected with the sale of the varieties to which we find honoured and respected names affixed, but which on trial we cast aside with a feeling of vexation, or something stronger?

A perusal of the French lists for the five years, 1861-5, will afford sufficient evidence of this. From them I glean the following, with the names of the raisers:—

Roses.	Raiser.
James Dickson	Eugène Verdier.
Richard Smith	"
Mrs. Charles Wood	"
James Mitchell (Moss)	"
John Crauston (Moss)	"
George Paul	"
John Nasmith	"
Souvenir de William Wood	"
Rushton Radclyffe	"
John Keynes	"
William Bull	"

I am not certain that M. Eugène Verdier is the raisor of the last two; he had, however, a share in the "*édition*."

Robert Fortune	Ducher.
Princess Alice	"
William Paul	Guillot père.
Mrs. Freeman	"
Souvenir de Lady Eardley	"
Mrs. William Paul	Charles Verdier.
John Fraser (Moss)	Granger.
John Standish	Trouillard.
Reynolds Hole	"
Mrs. Standish	"

The last two I believe were sent out by Mr. Standish.

Peter Lawson	Thomas.
John Veitch	Levêque et fils.
Rev. H. Dombrain	Margottin.
John Waterer	Portemer.
Arthur Young (Moss)	"
Henry Martin (Moss)	"
Viscountess Douglas	Gonod.
Deuil de Prince Albert	"
Lady Emily Peel	Lacharme.
Charles Wood	Portemer fils.

I have taken the liberty of substituting the dear old Saxon "Mrs." for Madame, believing that the worthy ladies represented in the above list, being Britons, are not ashamed of their native land.

Of the thirty-one above named three only are in Mr. Radclyffe's list of the best Roses—viz., Mrs. Charles Wood, Mrs. W. Paul, and Rushton Radclyffe. The last, although worthy of the place assigned to it as a first-class flower, is, to my great regret, a failure here from defect of constitution, and, like Gloire de Santenay, Furtado, and François Lacharme, must be given up in soils not naturally suitable for Roses.

It would be an injustice to omit any honourable exception to the majority of the French Rose-growers as regards the number and quality of their productions: M. Charles Verdier has sent out but few Roses from his establishment, but these have in nearly every case proved to be of great merit. Besides Mrs. W. Paul, above mentioned, we are indebted to him for Duchesse de Caylus, Vicomte Vigier, and François Lacharme, as noticed in the previous paper; his announcement of Paul Verdier for the next season may, therefore, be anticipated with some degree of confidence.

Of the remaining twenty-eight varieties there are three others that may be considered deserving a place in the rosery, their habit and colour being good; but their form is not up to the standard now raised so high by such flowers as Lord Macaulay, Chabrillant, Senateur Vaisse, Madame Victor Verdier, Duchesse de Caylus, and others. These are John Keynes, Charles Wood, and Viscountess Douglas; the last is surpassed by others of its colour.

The others can be disposed of in a few words. Peter Lawson is fine of colour, but too often shows a yellow "eye." Mrs. Standish is a pretty light rose, but uncertain, and only opens well in favourable seasons. Reynolds Hole is a pardonable mistake; let us hope that our amiable and respected rosarian may soon have a representative worthy of him in the Queen of Flowers, to whose interests he is so loyal and true.

Bourbon Roses are not in very high favour as a class, always excepting Malmaison, Acidalie, Baron Gonella, and to which may be added, with a slight qualification, Louise Margottin, or Madame de Stella, Celine Gonod, Sir Joseph Paxton, and Rev. H. Dombrain, the last two being the best of their colour in the class with English names, or any name.

Moss Roses are too rarely seen either in the garden or on the exhibition table; yet, what more beautiful than the old Crimson and its variety called Lanei? In the above list are five Moss Roses. Is there any one between Land's End and John o'Groat's house who knows anything about them? It would be a waste of space to offer any comment on the others given in the list, although they represent names most distinguished in English horticulture.

4. Nomenclature—Abuse of Terms.—It is quite reasonable that the raiser of any new variety of flower should assign to it such a distinctive name as his fancy or interest inclines. Generally the appellatives given to English flowers are well-selected and short; for, undoubtedly, short names are the best and easiest to be remembered. When we turn to the nomenclature of French Roses we often find the opposite of brevity, in some instances no less than six words being used to designate a single variety. We cannot complain of the grand array of princes, dukes, duchesses, marshals, generals, and other high and mighty personages when they represent known and distinguished individuals; but we do stumble over such appellations as Souvenir de la Reine d'Angleterre, Triomphe de la Terre des Roses, Souvenir de Bernardin de St. Pierre, La Baronne Pelletan de Kinkelin, and which when uttered by those unacquainted with the French language have a very odd and even ludicrous effect; still more so the contractions very often and naturally applied to those lengthy designations for which our French neighbours appear to have an especial aptitude. I know of an instance which afforded me much amusement when it occurred. An honest, hard-working, but somewhat illiterate gardener in this neighbourhood, whose ideas of orthography are rather misty when any departure from the strictly phonetic principle is observed, labels his Roses for his own and others' recognition. When the name is copied from a catalogue all goes on rightly enough; but a catalogue not being always at hand, our friend is left to the resources of his own memory. Some very curious derangements are the consequence. The instance that amused me was the well-known Général Jacqneminot, which was marked General Jack-me-not, the syllables being distinctly separated. It is very usual to recognise that Rose about here as "General Jack," Charles Lefebvre as "Charley," and Jules Margottin as "Old Jewels." Mr. Radclyffe knows similar cases, I believe. What Xavier Olibo will become it is not easy to guess, unless, as "D., *Deal*," conjectures, "Holybones."

These cases are simply absurd, but not altogether unnatural, nor inexcusable. Much more deserving of notice, in my opinion, is the abuse of a term that has now been many years applied—I mean the term Perpetual, as used to designate what

is now the most important section of Roses as distinguished from Bourbons, Noisettes, and other Hybrids. It has been more than once correctly remarked that this term is an abused one; then why perpetrate it? The word perpetual not only does not express what the Rose is, but also it is not the equivalent for the word the French use—viz., *rémontant*. Now, the word *rémontant* does express, as nearly as it is possible to find any word, the idea intended to be conveyed; but as we have no equivalent English expression for it, it is worse than ridiculous to make a floundering attempt at translating a word which admits of no translation. The usual procedure in such cases is to adopt it; there can be, therefore, no more impropriety in designating this particular section of Roses Rémontant Hybrids than in calling a fiddle a violin. The French themselves make no attempt to translate such words as "jockey," "shunt," "wagon" (with one *g*), "milord," &c., although these words contain letters and sounds the very opposite of their adopted orthography and pronunciation. In the same way we accept such phrases as *sang-froid*, *aide-de-camp*, *beau-monde*, &c., in their original signification, without essaying to render them into English.

Upon the ground of common usage, then, I venture to suggest that the term Rémontant Hybrids should be substituted for the incorrect "Hybrid Perpetuals."—Adolphus H. Kent.

(To be continued.)

ICE CELLARS.

I never knew until I read Mr. C. Short's communication that it required any great care to keep ice in an ice-well, where such a well is high and dry, provided you put in the ice when it is in pretty good order.

I have to keep ice in what were the cellars of the old mansion. There is a lake running close up to the passage door, and the water rises within a few inches of the floor. The ground about the cellars is also very wet and boggy. The walls are what I call dry walls, being built without cement or mortar; and the roof, a span, is of slates. The height from the level of the ground to the top of the roof is 6 feet, and, in fact, there is more roof than cellar. Any one accustomed to ice-keeping will at once perceive that it is very difficult to keep ice in such a place. Do what I would, or rather the men, for I allowed them their way, the ice always dwindled down to a few barrowfuls by August, and we never begin to use the ice before that time.

I ought to have stated that we have three doors to the cellar, and that the passage is 20 yards long. Any one can imagine the draught of air that rushes towards the ice when a man uncovers those three doors and runs up and down the passage twice or thrice with a basket of ice to fill his barrow outside.

I asked the men if they never covered the slates or roof. "No," said one, "for the water would lodge in the roof and make it damper than it is." "Do you not fill the cellar up to the top of the roof with ice?" The answer was, "No; only level with the top of the cellar, otherwise we cannot get the straw in.

As the ice always diminished so much by August, I thought it was time I had my own way; so last year I had the small cellar filled up to the top of the roof on the 5th of March with the worst lot of ice I ever remember carting. I then had the roof covered outside with 18 inches of soil. I opened the well early on a frosty morning in April, when the ice had sunk a little, and gave it a good soaking of water, which froze as it was poured in, and then covered up well with straw. The result was I had a better supply out of one cellar than I ever had out of two before.—T. Elcome.

Crystal Palace.—There appears to be every probability that the portion of the Crystal Palace which was destroyed by the calamitous fire on the 30th ult., will speedily be restored to its original perfection. The shareholders and season-ticket-holders will, it is understood, contribute largely to this object; and a movement has been originated by Mr. Francis Fuller, one of the founders of the Crystal Palace, to promote a public subscription in aid of their exertions. He believes that 1,500 persons can be readily found to subscribe or collect £100 each, which would suffice to restore a building which may be said to be of national importance, and which has so greatly tended to the refinement and social progress of the people. Many offers of sums of this amount have already been received; an influential Committee is being organised, and it cannot be doubted that all classes of society will cheerfully contribute, according to their means, to accomplish the desired object. M. Blondin has addressed Mr. Fuller, expressing his deep regret at the loss which the public have sustained, and his desire to give, as his contribution, two gratuitous performances on the high rope in the Crystal Palace, in aid of the Restoration Fund, which will, in all probability, produce a considerable sum.

THE ROYAL HORTICULTURAL SOCIETY'S EXHIBITION AT BURY ST. EDMUNDS.

The Royal Horticultural Society's Exhibition at Bury St. Edmunds in July promises to be a great success. Chiefly through the exertions of Mr. D. Fish the guarantee fund amounts to more than £1160, and the special prizes to nearly £260. The schedule of prizes will now soon be issued. They vary from £7 to £1 for stove and greenhouse plants in small numbers—from six to twelve specimens, so that the classes of competitors may be very inclusive. Fuchsias, Pelargoniums, Gloxinias, Achimenes, Liliums, Petunias, Ferns, cut Roses, Pentstemons, Delphiniums, Fruits, &c., are all to be exhibited in small numbers for the same good reason.

The special prizes are as follow:—

	£	s.	d.
Royal Horticultural Society of London, for Palms and Fine-foliaged Plants	25	0	0
The Ladies of Bury, for Orchids, a £20 gold cup and one of £5	25	0	0
The Town of Bury, for Ferns, three cups, £15, £10, and £7..	32	0	0
Ditto, for Lycopodiums	5	5	0
Ditto, for the best window plant grown by a cottager, a silver watch	3	3	0
The Borough Members, for best and second-best Hand-bouquets for Ladies, 5 guineas and 4 guineas	10	10	0
The Rev. Frederick Cheere, President of the Bury Horticultural Association, for an Essay on the Diseases of Plants	10	10	0
Eye Horticultural Society, for the best 24 Roses Grown by an Amateur, a Member of any Horticultural Society in the County of Suffolk	10	10	0
Woodbridge Horticultural Society, for the best 12 Picotees Grown by an Amateur	5	5	0
Stowmarket Town, for the three heaviest bunches of Grapes, a gold medal	10	10	0
Ipswich Town, not decided	25	0	0
Thetford Town, not decided	10	0	0
Suffolk County, not decided	25	0	0
Suffolk Gardeners, for the best 12 Roses Grown by a Suffolk Gardener	7	7	0
Ditto, for the best 12 Seedling Variegated Pelargoniums ..	5	5	0
The Proprietors of the *Gardeners' Chronicle* a silver cup, value £20, for the best Collection of Fruit and Vegetables—namely, of Fruit, any Five of the Following Eight Kinds, one dish of each—Grapes, Melons (two Fruits), Strawberries, Gooseberries, Currants, Cherries, Raspberries or Apples (of the Crop of 1866); and of Vegetables any Eight of the Following Fourteen Kinds, one basket or bundle of each—Peas, French Beans, or Scarlet Runners, Broad Beans, Cauliflowers, Cucumbers (brace), Summer Cabbages, Early Carrots, Turnips Artichokes, Onions, Spinach, Rhubarb, Potatoes, or Mixed Salading. Open for competition amongst all Comers	20	0	0
The Proprietors of The Journal of Horticulture, for the two best Desserts, consisting of not less than Seven Kinds of Fruits of 1867, arranged as for the Table, combining Quality of Fruit with Taste of Arrangement. Open to Gentlemen's Gardeners and Amateurs only. Two First Prizes of the Value of 10 guineas each	21	0	0
N.B.—Only one of these Prizes can be taken by the same person.			
Mr. Samuel Barrett, Hardwicke, for the best Collection of Vegetables Grown by a Cottager, a three-guinea watch	3	3	0
For the best Kept and Cropped Allotment, 1½ guinea; Second ditto, 1 guinea	2	12	6
	£258	0	6

There are also numerous prizes for cottagers' plants, fruits, cut flowers, and vegetables.

PLANTING PEAR TREES.

I have to thank "T. R." for his criticism of my paper on Pear culture, and beg to assure him and your readers there is an error of mine, or the printer's, at page 460, of No. 299. "Holes 9 feet square should be dug, &c.," should read "Holes equal to 9 square feet should be dug, &c." The difference, then, between the holes which I recommend and those advised by "T. R." is not very material. "No hole in any cultivated garden," writes "T. R.," "need be more than from 3 to 4 feet in diameter, and 20 inches deep," and these dimensions, I may

add, are twice as wide and deep as I find necessary for planting ordinary-sized trees, such as those obtained from nurseries, when the ground has been properly trenched previously to planting. In trenched ground, all the hole that need be made is one wide enough to admit the roots without turning their points up, down, or aside against its sides; and it is deep enough if it allows of the fibres being covered with 3 inches of soil. If "T. R." finds a hole 20 inches deep necessary to plant a Pear on the Quince stock, I must say he plants much deeper than I do, or his ground is of that uncultivated and unprepared character as to require holes "9 feet square" in addition.

"T. R.'s" other objection is to covering the junction of the stock and scion with 3 inches of soil, for this, "as fully pointed out in your columns last spring, pages 180, 193, leads to injurious consequences, for, besides placing the tree by far too deeply in the soil, it induces the putting forth of roots from the graft, by which the effect of the Quince stock in giving fertility is destroyed." Who, last spring, pointed out the injurious consequences of covering the junction of the stock and scion with soil? "T. R.!" His conclusions based solely on his having some Louise Bonne Pears on the Quince rooting from the part of the scion covered with soil, the trees ceasing to be productive, which would lead to the inference that Pears on the Pear stock are not so fruitful as these on the Quince stock. Now, I have trees of the Louise Bonne on the Pear stock, that annually produce heavy crops of fine fruit; and we have scores of trees, both on walls and in the open ground, on Pear stocks, producing an abundance of fine fruit: hence it follows that the Pear on the Pear stock may be fruitful. I thought that the one great merit of the Quince, as a stock, was in giving early fertility to the Pear, not greater or more extended fertility than the Pear stock; but, if I understand "T. R." aright, a Pear rooting from the part covered with soil, it being worked on the Quince, ceases to be productive, to which he should add, Unless the tree is not to be kept so dwarf and stunted as it was before, and the soil is not favourable to the fertility of the Pear on its own roots. In my soil it does not in the least matter whether the Pear tree be fed by its own roots or those of the Quince; once it commences bearing it continues to crop well afterwards, and can be kept very dwarf by a moderate amount of summer-pinching. The soil is a rather light loam, about 15 inches deep, on gravel. On heavier and deeper soil the Pear tree may root so deeply that the effect of the Quince in giving fertility may be destroyed, for the Quince has a more shallow disposition of roots than the Pear: hence the tree rooting from the graft will have a tendency to wood growth rather than the formation of fruit-buds, the good offices of the Quince in giving a more dwarf growth being destroyed.

"T. R." accepts as proven that a Pear tree covered with soil above the junction of the stock and scion does root from the latter. I must allow that I have seen that; but I cannot admit that it invariably occurs, for with some kinds of Pears it is the exception rather than the rule, and is in most soils a tardy process, though in some it may be general; but such I have not found, and I have had experience of Pears on Quince stocks in six different soils and situations.

When I find Pear trees on the Quince, with the junction of the stock and scion covered with soil, rooting from the graft so freely that their bearing, health, and longevity are interfered with and impaired, I will gladly make a public recantation; but until then I must be excused covering a very ungainly swollen junction, and exposing no part of the stock to the drying influences of the sun and air, but using it as a root-forming, consequently food-collecting, medium. In the meantime "T. R." will, perhaps, inform us whether budded trees root as freely (or at all), from the Pear as those that are grafted, and how soon rooting may be expected to occur after the junction is covered with soil. I have my own particular experiences on these points, and reserve myself for confession at a fitting time and place.

"T. R." concludes with a recommendation. I may do so likewise; and it is—Should those having Pear trees on Quince stocks, with the swollen junction hidden by soil, perceive them making an undue amount of wood not to be restrained by summer-pinching, lift these in autumn and plant them, after searching carefully for roots from the Pear where covered with soil, removing these, if any, so that the soil will reach only to the swollen junction, and the trees will be as fruitful as ever; and if your soil is not unfavourable to the Pear, care nothing about the roots from it, for no tree lives so long, is so healthy, or so well fed as by its own roots; also to gain fruitfulness, plant on a raised mound, by which the roots will be kept near the surface, and one of the main advantages of having trees on Quince stocks will be secured.

Finally, though my stock of "Pear trees, old and young, on Quince stocks," is not equal to that in "any other garden in Europe," I have had sufficient experience to prove that I recommend a *sound*, but I should not feel justified in considering it "the only sound method of culture." Others have a right to their conclusions, and experience is fully entitled to weight. —G. Abbey.

OUR VINES.

(*Continued from page* 25.)

For a long time we had looked forward to the fruiting-year with great interest. Should we really have Grapes? Would those fine buds develope into bloom, or spend all their energies in leaf and cane? We could but wait and hope; but we waited with an eagerness only amateurs can feel.

Our Vines broke in March, all but Lady Downe's, she put forth shyly as if only half knowing what she meant to do; but then it did not matter much, for we knew she was a rampant grower and took long strides. To our impatient waiting it seemed as if the blossom would never show itself. After weeks of anxious, almost hopeless inspection, the bloom made its appearance, at least what we thought would turn into bloom—a round hard lump, like a great Cob nut, covered all over with minute excrescences. Out of this lump we supposed the bunch of Grapes would come; but day after day we looked in vain for any sign of progress. If there was any growth it was all internal, did not manifest itself to our closest observation; and yet the Vine was not idle, the work was going on though we saw it not. After long waiting these little excrescences seemed to part from each other, and form stalks or stems of their own, so that as time passed the contour of the future bunch was fully shewn. But, then, were these the very berries to enlarge into the future Grapes, or simply the flowers which must first open before the fruit could form? In our ignorance we did not know, could not make out. We had grown Vines for years at South Field, or rather the gardener had, yet could not remember ever having seen them in this stage of growth. To be sure our pomological curiosity had never carried us so high. We wearied ourselves trying to find out from books, sought long, but the bit we wanted we could not find. Cousin Herbert said the "whole lot of gardening writers were donkeys; they wrote for themselves so that they might tell nothing but what was already known." Our Vine doctor laughed and said, "Some things were so simple people never thought to write about them" However, the question was settled, the bloom had not yet opened, and it must do so before any fruit could be.

"It is my firm opinion there never will be any fruit," said Cousin Herbert.

"Well, I always said the Vine border was much too rich," said Uncle Tetley; "as George says, you will grow plenty of coarse leaves minus fruit."

"I do not reckon much on what George says," said papa; "he is amazed at your success, and is afraid your Vines will one day be better than his own. As for the Vine border being too rich, what is it when they bury dead horses in it?"

"Disgusting in the highest degree," said Aunt Margaret; "I would never eat another Grape as long as I lived, if I thought that was the usual practice."

"Not very pleasant certainly to any one troubled with suggestive ideas," said Cousin Walter.

"But, what is to be done?" said Cousin Herbert. "I would not like to be without fruit this year. We have waited long enough, never mind the canes whether they be thick enough, or ripened enough, or strong enough, only let us have fruit."

"Never mind what people say about your border," said our Vine doctor very quietly. "I assure you it could not be better, and I dare venture to say you will have half a score bunches on every Vine. What is the good of putting yourself into such a state, and keeping me in a perpetual fever by your doubts? I am half afraid I shall go over the line yet. Put on a little more heat, do not open quite so soon, and shut up earlier, and you will have fruit, fine fruit too, this year. The bloom wants a little petting to open, not that the flowers are very brilliant or very fragrant, they are neither the Glory Pea of New Zealand, nor Stephanotis. It is only the after-results that make the bloom of value."

So Uncle Tetley would not have the house opened until much later in the day; indeed, he would not have it opened in

the least unless the day was very sunny; and we were not surprised when, a week or two afterwards, Cousin Walter came running in, saying, "The Vines had the red spider; all the high-up leaves were all but coloured with them." What was to be done? We dare not syringe for fear of the bloom, which was just opening.

"Sweep them off with a little brush," said Janet.

"You could almost as soon empty the sea with a bucket," said Cousin Walter.

So there was nothing for it but letting the two grow together for a time. When the berries were once fairly set we could keep down the insects with syringing; but the red spider turned out to be only brickdust, to our great joy and Cousin Walter's annoyance.

During May the bloom opened, but the berries set slowly; they seemed to have a predisposition to twirl and twine themselves up, and we had our fears lest they should run right off into tendrils, as they had done the year before. Again we hung up our little weighted bags on the bunches and tried to keep them down, but to our great disappointment much of the bloom dropped off, leaving only a bare twisted stem.

After all our fretting and worry we had a great deal more fruit, every one said, than we ought to have had the first year. The berries when once set enlarged rapidly, every week there was even measurable difference in the breadth and length of the bunches. There was no looking back now, they pushed on as if vieing to outdo each other—went at the rate tired horses go when their faces are set homewards. The number of bunches had to be lessened; on several of the Vines they were growing too near each other. Cousin Herbert said "he would thin them." I am sure his heart ached the while. It seemed a cruel thing to cut away the very good we had waited for so long.

After this there came the time of thinning out the berries. A pair of scissors was bought for the purpose. Cousin Herbert commenced, but soon gave up, saying "the operation was too delicate for his thick fingers." Papa said, "he would send George over to do it for us." Kate and I declared "the berries should go unthinned first, we would not have him! one professional was enough to work under." Then Cousin Walter would try, but he cut away right and left, without ever thinking or looking what he was doing; taking off whole shoulders at one snip, or a nice cluster of berries that had ample space to enlarge in. It was too much trouble to pick out the poor, little, thin, crowded berries clustering away out of sight behind the big ones; "Besides," he said, "it was not fair play, let the dwarfs have a chance of becoming giants." Then Aunt Margaret would try, but she pricked, and bruised, and cut them in all manner of ways. The "syrup" Janet called it, but it was more akin to vinegar, dropped upon her peach-coloured dress and stained it. "I cannot think how it is Kate, dear," she said, "but I am always cutting the berries instead of the stalks." Then Uncle Tetley would try, and he chose a sunny day for the performance, and very sunny it was, the glass standing up at 80°, though every breath of air was let in that could be—doors, and windows, and ventilators wide open. Poor Uncle Tetley did not do much—ten minutes and he was done for, and more than half the time he spent rubbing the perspiration from his red face with his white handkerchief; he puffed, and sighed, and finally threw down the scissors, and rushed out into the cooler fresher air, exclaiming, "Every man to his trade, I would rather pay a gardener £5 a-week than do that. It's murder complete! I believe, Margaret" (for, of course, Aunt Margaret was all sympathy), "I am so melted I shall never stiffen again."

Then Kate and I did what we could in some fashion or other. We tried to do it in white kid gloves, for Janet said every berry we touched would be injured, but our hands became hot, and the gloves so stuck to them we could not move our fingers, so were obliged to tear them off. It was neck-breaking work and very hot, though we chose the coolest time of the day, and did not do much at one time. "I am not sure, Maud," said Kate, "which is best or worst, these vapour-baths at sunny midsummer, or lonely vigils in cold, and dark, and dust in midwinter."

All went on well for a few weeks, then the Vines, or rather the berries, seemed stopped in their progress, as though they had received a sudden check, or something or other which had frozen-up their energies, not that they appeared to be ailing or growing bad, they were simply standing still. It might be they were resting after their long hard work. The rest was long enough to awaken our fears. We had heard of Grapes all at once ceasing to grow and never ripening. Surely such a fate was not coming to ours? There was nothing for it; we must read-up again our old books, and find out the best thing to do under the circumstances. At last we decided that a syringe in warm water every afternoon when shutting-up was the best remedy. Perhaps we followed this too closely, for it brought on what George called a fatal disease. Many of the berries were covered over with small specks of brown. These specks spoiled the smooth uniform greenness of the berries, even if they did not lead to anything worse. George called it the mildew or mould, and said it had come with the "absurd practice of syringing late in the day. I tell you what, Miss, they never will be good for anything, and Mr. Herbert may cut them all off at once and carry them away. If he do not, the canes will be infected."

"Whatever it is, I am sure it is not mildew," said Kate, when I told her what George said. "There is no mould or fungus about it. Why, Herbert can take it off with his penknife, and there is no mark left on the berry underneath."

"Then you do not think I need fetch up the wheelbarrow yet," said Cousin Herbert.

"Not for the mildew," said Kate. "I am afraid we are going to have something worse. Several of the bunches on Lady Downe's are shanking."

"Shanking! Dear me, how learned we are!" I said. "Pray what does that mean?"

"Why, the stem or shank dries up so that it will not feed the berry, and then the berry becomes wrinkled, gets less instead of bigger, and never ripens."

Here was a real grievance we all went in to see, for Lady Downe's was a general favourite. Four of the bunches had an old, dried-up, shrivelled look, it was very possible all the others might become so. What should be done?

"I think, Kate, we had best cut them off at once, they are not at all respectable-looking," said Cousin Herbert.

"No, wait a bit," said Uncle Tetley, "they may improve. In my opinion they are only scorched by the sun, they look as if they were pinched of water."

"They seem to be always ailing," said Janet, you cannot be managing them right."

After this there was nothing for it, we must send for our Vine doctor, we could not rest without. Janet said he would laugh at us and Cousin Walter, that we were "very silly, for it might turn out to be nothing after all."

"Well, I dare say we can get over both these troubles," said Kate, "better than losing our fruit."

So he came, and very gravely looking round exclaimed, "What is the matter you should send for me all this long way? You will drive me mad yet. I see nothing amiss with them."

Then we pointed out the shanking and the brown spots.

"Why, the fact is just here, you girls want to do things better than other people. Did you ever know any one rear chickens without losing at least fifteen per cent., and I assure you few people can grow Grapes without some going wrong. Every flower that opens will not set into a berry, the Queen's own gardener could not make it; and every berry that sets will not grow to its full size; and every full-sized berry will not always ripen equally to the same depth of blackness. As for Lady Downe's, she is rather given to shanking, and then, perhaps, we have let her have rather too much to do. She is a fast worker, and yet that is no reason why she should be put upon. You see she has twelve to fifteen good sound bunches left."

"Shall we cut off these unsightly ones and so relieve her?" said Cousin Herbert.

"Well, no. I am not sure it would. You see the Vine has got over the pull and the strain, and is now ready for the down-hill work, and yet they do not look well."

"But, then," said Aunt Margaret, "what is this on the berries? My brother's gardener thinks it is the mildew, and that it will destroy all the fruit both for this year and next."

"Nonsense, it is no such thing; it is caused by syringing with water that has stood in an iron cistern. It is rust from the water settling on the berry; and, indeed, you must not syringe any more, for these berries are coming to their full size fast, and will soon be showing colour. You must be very careful for the next two months; water your plants as little as possible, and then early in the morning; keep a warm, dry, airy house; if it rain or be windy do not open, but when the sun shines open freely as much as you can; if a cloud go over and it is cold, close all up again."

"That is certainly a great deal of trouble to be constantly running in and out, always looking for wind or rain-clouds. I am sure a gardener could not do that," I said; "some of his work might be mowing a lawn half a mile away."

"Well! But if to grow as good Grapes as any in the land is his hobby, he will take care his work at such hours of the day is not even half a quarter of a mile away. That is where many gardeners miss it—they will not give the thought and trouble necessary; they will give work, hard work too, but not thought. Never you mind the trouble, Miss Kate, it is only for a time; give them plenty of fire on dull, cold, wet days, and plenty of fresh air on clear, warm, sunny ones, and you will have first-rate Grapes yet, though your poor Vines have had nearly every malady under the sun."

So once more we sailed out into smooth water, our Vines grew and flourished; the bunches enlarged, they were tied-up by the shoulders, opened out, and made the most of, and there was a bright glow of health about them as though they had passed through all their troubles and were the better for it. Lady Downe's seemed to carry her fifteen bunches (for we had cut away the ill-looking ones), with regal pride. It seemed to be no effort to her to do it, she might have done more and not suffered in the least. What great, round, fleshy, plum-like berries they were, growing out of a thick stumpy-kind of stalk!

It was a sort of impulsive Vine, this Lady Downe's, making all its growth by fits and starts; and when the colouring-time came the berries presented the oddest, strangest appearance, just as if they had been dashed at here and there with a black-paint brush, a regular daub with fine splutters all up and down over the green. These black patches increased until all the berries were dark. Aunt Margaret said "they looked as if the sweeps had been in during the night shaking their soot-bags."

Then the Black Hamburghs, they coloured as they had grown, by a slow but sure process, never having to turn back, for they never made a false step. Uncle Tetley said "they did their work by the day, not by the piece, and it did not seem to matter a great deal whether they did much or little." They changed gradually from a deep green to a pale, delicate, Bohemian-glass colour, becoming darker and darker as the weeks passed until they were coal black.

Then the small round berries of the Reeves' Muscadine formed themselves into small round bunches, changing very little in colour as they ripened, brightening up, but not much, as they took the last faint tinge of yellow. Then the Muscat Hamburghs, with their long, slender, oval berries, making long, slender, oval, most graceful, most exquisite bunches. There was sparkling brightness about them, reminding one perpetually of the poet's line—

"A thing of beauty is a joy for ever."

The heavy berries hanging on their slender stalks seemed like transparent bags into which some invisible hand poured coloured nectar, drop by drop, every added drop showing a deeper colour, and a higher tide-mark, until the little bags were brimfull. With pleasure not unmixed with wonder we watched their onward growth. If we had spent idle time before, we spent much more now.—MAUD.

(To be continued.)

VINE BORDER COMPOST.

I THANK "FAIR PLAY" for noticing my incomplete quotation from Mr. Pearson's book. I feel that I ought to have said *some* kinds of green turf, &c. I had been reading Mr. Thomson's book, and thinking that his method of preparing turf was much better than using it green, as recommended by Mr. Pearson. Mr. Pearson is always honest in all he says and does, and I have no doubt that he has found his turf to be good even when used green, as the fine loamy pastures in his neighbourhood give a turf of first-rate quality. I happen to live in a district in the south where green turf is a most dangerous article to employ, as that from light calcareous pastures is so full of grubs, from those of two or three species of cockchafers to those of different species of Tipula, that the roots of all trees and plants are soon destroyed if it is used in a fresh state.

I once planted some young fruit trees on some light calcareous soil which had for many years been a pasture, thinking that by turning in the turf I should not have occasion to use any manure; the trees suffered fearfully, grubs without end, aided by wireworms, having barked and cropped the roots to a great extent, hence my condemnation of green turf as a portion of any compost, for inexperienced persons might use it and suffer as I have done. Mr. Pearson is quite right in recommending his fine green turf, but I think a caution should have been given.—FORWARDS.

PEAR CULTURE.

(*Continued from page* 27.)

BORDERS AND SOIL.—The borders for Pears should equal in width one-half the distance apart at which the trees are planted, and should in no case be less than 12 feet wide. For trees upon the Quince the border may be 3 feet less in width than for those on the Pear stock.

In depth the border should not be less than 2 feet, nor exceed 2½ feet. In all cases it should be well drained; and where the subsoil is of a cold wet nature, in addition to draining there should be a concreted and rubble bottom—that is, the bottom should consist of a layer of rough gravel or lime riddlings 3 inches thick, rammed quite hard, then of another layer of lime riddlings half the thickness of the first, and made as hard as a barn floor; and lastly, of another thin layer of equal parts lime riddlings and fine gravel, made to the consistency of thin mortar and rammed hard after it has stiffened. In this way a barrier will be formed through which the roots will not pass; and 9 inches of rubble upon it will afford free drainage for the water passing through the soil, add to the warmth of the border, and check long sappy growths, which are never productive of fruit.

When it can be obtained the top spit of a rather strong loam is the soil to be preferred, and if the turf be taken with it no manure need be applied. Where the soil is of a light nature one-fourth cool manure may be added—cowdung is best. The border should be drained to a depth of not less than 3 feet, and where the soil is of a loose nature one drain along the front, or 4½ feet from the walk, will answer; but where the subsoil is adhesive there should be a drain 1 foot from the wall, and another 9 feet from it outwards towards the walk, both running parallel with the wall. These drains should have proper falls and outlets, and be formed of three-inch drain-tiles.

Fig. 1.

The ground in all cases should be trenched to a depth of 2 feet, and, where the soil will allow, 3 feet is not too deep. If a proper border, which is always the best and cheapest in the end, is to be made, a layer of sods may be placed on the rubble; and the earth, as it is brought, should be placed with the grass side downwards, till 9 inches or a foot higher than the depth desired, so as to allow for settling, the amount of which will be equal to about one-third of the depth of soil. The soil should not be trodden upon, more especially if the ground be at all wet, and the worst time of all to make fruit borders is when it is so; dry weather ought to be chosen.

In wet soils and cold situations much may be done towards rendering the soil drier and warmer by raising the border. Unfruitful trees are chiefly those in borders not properly drained, and where no attention has been paid to preventing the roots going down too deep; but if these borders had been raised, well drained, and shallow, and if means had been taken to prevent the roots going down, the trees would have been fruitful and healthy. Where the subsoil is of an adverse

nature—that is, wet or sandy, the place where the tree is planted should be made quite impenetrable to the roots in a downward direction. They have a disposition to go down by the wall, and that may be prevented by concreting a space equal to 3 square yards by the wall where the tree is to be planted. The concrete should be quite close to the wall, and about 15 inches from the surface. Some place a flagstone or slates immediately nnder the tree by the wall, and this to some extent prevents the roots going down, and induces them to spread themselves through the border.

Fig. 1 will serve to illustrate my views as to borders where the soil is heavy, the subsoil retentive of moisture, and the situation low and wet, subject to spring frosts, as low situations usually are. To prevent the roots going down, the bottom of the border is concreted at *a a*, and drains are laid at *b b b* to carry off superfluous water. *c c* Is the border 2 feet deep, formed of rather strong loam, the top spit, without admixture. *d* Is the ground level; so that the borders, *c c*, for trees against the wall, and at *e* for pyramids and bushes on the Quince, are considerably raised.

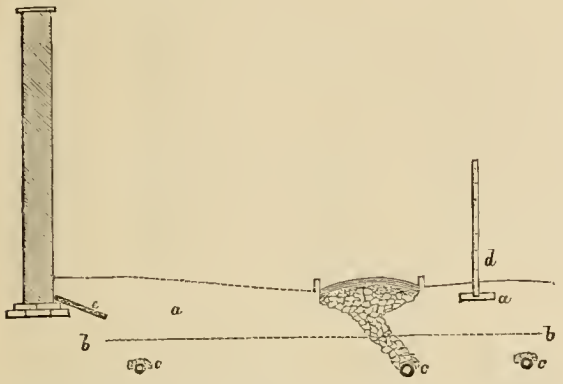


Fig. 2.

Fig. 2 is intended to show a border where the situation is not low nor wet, and the subsoil loose or free, as sand or gravel, but not free from water lodging. *a* Is the border trenched 2 feet 6 inches deep, or to the depth shown by the dotted line *b b*. c c c Are drain-tiles to carry off water passing through the soil. *e* Is a space flagged, slated, or concreted to a distance of a yard from the wall, 3 yards in length, and 15 inches from the surface, to prevent the roots going straight down by the wall into the subsoil. *d*, Espalier.—G. Abbey.

(To be continued.)

NOTES AND GLEANINGS.

The following are from Mr. G. J. Symons and other authorities:—

—— The old tedious process of skeletonising leaves by slow decay in water is superseded by the following, communicated to the Edinburgh Botanical Society:—"A solution of caustic soda is made by dissolving 3 ozs. of washing soda in 2 pints of boiling water, and adding 1½ oz. of quicklime, previously slacked; boil for ten minutes, decant the clear solution, and bring it to the boil. During ebullition add the leaves; boil briskly for some time—say an hour, occasionally adding hot water to supply the place of that lost by evaporation. Take out a leaf and put into a vessel of water, rub it between the fingers under the water. If the epidermis and parenchyma separate easily, the rest of the leaves may be removed from the solution, and treated in the same way; but if not, then the boiling must be continued for some time longer. To bleach the skeletons, mix about a drachm of chloride of lime with a pint of water, adding sufficient acetic acid to liberate the chlorine. Steep the leaves in this till they are whitened (about ten minutes), taking care not to let them stay in too long, otherwise they are apt to become brittle. Put them into clean water, and float them out on pieces of paper. Lastly, remove them from the paper before they are quite dry, and place them in a book or botanical press."

—— Mr. William Kidd, so generally known as a lecturer and writer on birds and other domesticated pets, died on the 7th inst. at Hammersmith, aged sixty-four.

—— An appendix is just published to Pritzel's *Iconum Botanicarum Index*, a most useful work as a guide to all known portraits of plants.

WORK FOR THE WEEK.

KITCHEN GARDEN.

On Friday night the 4th inst., we had 35° of frost in Kensington, with 12 inches of snow on the ground. The Aucubas and other large shrubs have suffered severely. A thaw occurred on Saturday, and now that the snow has vanished we can resume operations in this department. See that the previous directions are carried out; if not, take the first opportunity when the state of the soil will admit. It is bad policy to tread upon trenched ground when soddened with wet, and the delay of a day or two will often be found a gain. *Beans*, to guard against accidents sow in pots or boxes, or on strips of turf, a moderate quantity of Long-pod Beans and Early *Peas* for transplanting. Place them in a vinery at work, or other place where there is a gentle heat, and when about an inch high remove them to a cold frame, secure from frost, to harden. The value of a little seed is nothing compared with the loss of an early crop, and if the weather prove favourable these transplanted crops will come in as soon as, and very often sooner than those sown at the latter end of the year. Embrace every opportunity of stirring the surface about the advancing crops. *Onions*, sow in a warm corner for early spring use, and plant out small ones of last year's growth for the same purpose and to bulb for kitchen use; the soil should be light and rich. *Shallots* and *Garlic*, plant out in light rich soil; draw a small drill, and fill it with charred refuse and lay the bulbs thereon, but do not cover them; they will by-and-by require a slight pressing down. *Sea-kale*, see that the fermenting material about it is not too hot; begin in time, and give it a gentle heat, or the stalks will be as weak as straws. Cover up a succession, taking care to place pots or a substitute over the crown to keep it apart from the fermenting matter, for notwithstanding all that has been said in favour of covering with leaves or ashes, &c., without pots, we feel sure that nothing will entirely do away with the earthy flavour which it thus acquires. Manuring and trenching as fast as the crops are cleared off will still be the principal feature here; turn over compost heaps in the frost, and procure a fresh supply if needed; make up all vacancies in Box-edgings, if the weather is open, and turn up gravel walks, leaving them rough for a time.

FRUIT GARDEN.

If not done in the autumn, prepare and wheel in soil for fruit trees which are to be removed, or for filling up vacancies on the walls; this, however, is far better done in the autumn. See that the drainage is perfect. Stake all newly planted trees, and mnlch them whether on borders or in the open ground. Continue pruning and nailing in favourable weather, and as fast as the trees on the walls are completed manure the border and fork it up. The quantity and quality of this manure must depend on the crops taken from the borders; it is never advisable to plant any very exhausting crops on them, but we are aware that in many gardens it can hardly be avoided, and when this is done fresh soil and manure must be added. We have a great objection to digging in manure on fruit borders where the roots of fruit trees can take hold of it, because we think it causes unfruitful luxuriance, but unless we could dispense altogether with cropping the borders it can hardly be avoided. In nailing, lay hold of the hammer in the right hand, taking a nail between the fore and mid fingers, with the

head inwards towards the thumb, and a shred between the forefinger and thumb; the left hand will then be at liberty to place the branch in its proper position, and all the materials will be ready for performing one operation in the most convenient manner. Cut the dead wood out of Raspberries; prune Currants, and, where birds are not destructive to the buds, Gooseberries also. Scrape moss and lichens off Apple and other fruit trees.

GREENHOUSE AND CONSERVATORY.

Although it is not desirable to shift the general stock of stove or greenhouse plants for a few weeks to come, yet under some circumstances a part may require being fresh-potted at this time. When such is the case, room must be made to keep them apart from the general stock for a short time afterwards, as their treatment will be somewhat different. Most soft-wooded plants require heading-back or pruning at the present season, and this should always be performed a sufficient time before the plant is repotted to enable it to make a fresh growth. It is often necessary, too, with this class of plants to dis-root them in some measure at this potting, and such is an additional inducement to defer it till the plant has made sufficient growth, say young shoots an inch long, to enable it to bear the operation without injury. Stove plants of similar habit will be much benefited by bottom heat and a moist temperature till active growth commences. Thin and tie out the shoots as they advance. Much of the beauty of plants consists in their having clean healthy leaves. Attend to the training of plants on wires and trellises. Fast-growing plants, such as Tropæolums, will require looking to frequently. Cinerarias will now require some assistance in the shape of weak manure water.

STOVE.

Little advance in temperature may be permitted here at present; wait for an increase of light, without which any application of heat and moisture will be vain. Let 60° without sun be the maximum, sinking several degrees at night. Endeavour to create motion in the atmosphere by admitting fresh air in very small quantities at a very low level. Some of the Lælias and Cattleyas will commence rooting, let them have attention and encouragement. Cymbidium sinense is a most useful plant for the drawing-room; it generally flowers about this time, and the scent is most delicious—equal to the most powerful summer Mignonette. A thorough search for snails and vermin should take place previous to potting, and all scale, moss, &c., must be cleansed from the leaves. Dry roots of Gloriosas, and a portion of the stock of Gesneras, Gloxinias, Achimenes, and other herbaceous stove plants may now be plunged in bottom heat to start them previous to potting. As the principal kinds of Begonias will now be showing bloom, they may be advantageously removed to the conservatory, previously staking them carefully to preserve their fine foliage from being damaged.

FORCING-PIT.

The following plants may be now introduced with every prospect of success, the plants being in good order:—Franciscеas, Gardenias, Hedychiums, Gesneras, Phajus, Daphne cneorum, Clerodendrons, Eranthemums, Honeysuckles, Sweet Briars, Cinerarias, Roses, Lilacs, Rhododendrons, Azaleas (both Chinese and the common), Dutch bulbs, Acacias, Kalmias, Polygala chamæbuxus, Pinks, especially the Anne Boleyn, Aloysia citriodora, Heliotropes, &c. It is not meant that these are all equally eligible for forcing, but that all of them may be forced if well prepared for the purpose in the previous summer, by early growth, early rest, and a potful of healthy roots. A day heat of 60° or 65° will suffice at present, sinking at night to 50° or 55°.—W. Keane.

DOINGS OF THE LAST WEEK.

Notes on storing ice will be given shortly; it will, therefore, only be necessary to mention that owing to the rough, wet, though mild weather commencing on the morning of the 6th, most of the other work has consisted in cleaning glass, washing Peaches and Vines, cleaning and moving plants, washing pots, &c., inside the houses and sheds, and giving all the air that could be safely afforded to vegetables and plants in cold pits and frames.

Excluding Frost.—Thanks to the covering and the snow, nothing has suffered from the severe frost, except such as will be at once referred to, and which, as serving to show how little artificial heat will keep out a frost not far from zero, may be more generally useful than giving a detail about different plants, which would be little else than a repetition of the doings of past weeks.

We have a long verandah, 10 feet wide, in front of a wall, with upright glass in front 10 feet in height, and roofed with a rounded canopy of zinc. In this verandah a large number of plants, such as Scarlet Pelargoniums, stood until the late frost. Before it came the plants had to be moved to one end, and the most tender were taken away; but there were some large vases draped with a thick covering of Ivy-leaved Pelargoniums that could not well be removed, and at the approach of frost these were covered over with mats and left where they were, close to the back wall, to take their chance. Though the place was kept close, and the air, therefore, still, the frost through mats and all nearly made wrecks of the trailing white Ivy-leaved Pelargoniums, which we partly expected, as hardly a better radiator of heat could be found than a roof of dark-coloured zinc. Of course, in such a dry still place, any frost could have been kept from plants if they had been deeply enough covered with dry hay or litter, but it was not desirable to do so.

Now for the converse, showing what even a small stove, or some borrowed heat may do in an otherwise unheated place. The verandah, of a similar width, is continued for 40 feet along the end of the mansion; but here it is much loftier and of a more architectural character, and is separated by glass doors, &c., from the part first mentioned. The height of the front, chiefly glass, and without any protection, is about 12 feet, the height from the floor to the centre of a low span-roof of thick ribbed glass being about 15 feet. The roof is concealed from the outside by an ornamental parapet, and thus the snow lay on it, unswept by the winds, during the three days of the severest frost. The back wall was the end of the mansion, and, therefore, was protected from the cold by fires in the rooms on the other side of the wall. A glass doorway at the west end of this 40-feet length, opened into one of these rooms, in which a fire was burning all day, and say until ten o'clock at night. The room not being used in the evening, the glass doorway was opened two or three hours, which would tend then to heat the air in this part of the verandah. With the help of the comfortable back wall, and the assistance of this open door for a time, such plants as Coleus were destroyed, but some large plants of Scarlet Pelargoniums, about which we were chiefly anxious, were not in the least touched, and even some rather large plants of Heliotropes, not very far from the door, showed no signs of suffering. Such pendant succulent plants as Nasturtiums were also uninjured. Some variegated Pelargoniums in vases within a few inches of the glass in front, unprotected by any blinds, did not suffer in the least. Something, no doubt, was owing to the dry back wall, with rooms and fires on the other side, but no chimney in the wall; something, also, to the air being dry, and the soil about the roots of the plants being rather dry; but the safety is chiefly to be attributed to the door being open between this part of the verandah and the living-room for a few hours. This door, be it noted, is at one end of this part of the verandah, and, therefore, nearly 40 feet from the other end, which, we may remark, is chiefly glass, and yet as respects the safety of such plants as Scarlet Pelargoniums, there is scarcely, if at all, a shade of difference between one end and the other. This may give a hint to those who are greatly perplexing themselves as to how best to ventilate and change the air in their plant-houses. The above simple facts prove that the opening of a door between the end of a room and the end of a verandah is capable of securing a double circulation of heated and of cold air from the farther end of one to the farther end of the other respectively, and that this would continue so long as the fire burned, or the one place was much warmer than the other.

If we were asked if we should be satisfied with such a borrowed mode of heating a plant-place, we would say, Decidedly not, as there might not always be the same favourable circumstances in such a severe frost, and it might not be suitable to be always fixing on the hardiest plants, and, besides, it is always best for one part of an establishment to be independent of the favours or the caprice of another, even as respects borrowing heat from a room; and, therefore, when flowering plants are to be kept in a place all the year round, we prefer that it should be independently heated; but still the simple facts show that thousands who would have their little glass house attached to their sitting-room but for the dread of flues, and boilers, and water-pipes, may accomplish their object by means of a small stove, or more simply still, by denying themselves the warmth of their sitting-room, by opening the communication between it and their pet plant-house during a few of the coldest hours. —R. F.

COVENT GARDEN MARKET.—January 12.

Supplies moderate, and French goods confined to Lettuces, Endive, and *Barbe de Capucin*, with the exception of a few bundles of forced Asparagus, which is at too high a price to obtain anything but a very limited sale. Pears now are almost over, and good dessert Apples are in request. There have been heavy arrivals of Potatoes, both coastwise and by rail, at former quotations.

TO CORRESPONDENTS.

*** We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed *solely* to *The Editors of the Journal of Horticulture, &c.*, 171, *Fleet Street, London, E.C.*

N.B.—Many questions must remain unanswered until next week.

Tydæa and Achimenes (*C. D.*).—All the species of each genus are so closely allied and so very much alike, that they are separated on account of differences which only a botanist would detect. The most noticeable differences are—Achimenes has a two-lobed stigma; the ovary bordered by a ring-formed glandular disk. Tydæa has a stigma two-cleft, and the ring-formed disk composed of five distinct glands.

Vine Cuttings (*G. Scutt*).—We have no cuttings at our disposal. You must write to the Secretary, Royal Horticultural Society, South Kensington.

Failure in Heating (*S. St.*).—Provided you obtain heat enough in the tank over the furnace, your failure is owing to having over your tank a bottom of wood and moss, and then a thickness of 10 inches of cocoa-nut fibre to plunge in, all three being the worst conductors you could have. For top and bottom this is what we would advise:—Let the spars of wood over the 3 inches of water remain, cover them over with a piece of zinc for a bottom, or thin slate; make this waterproof. Put a thin box inside the present one, as deep as your plunging material, but so as to leave a space free back and front of 1½ inch, to let the dry heat into the air of the propagating place. Pour a little water down when you want vapour; or better still, make a hole back and front, through the bottom, furnished with a plug, so that you can let vapour up from the hot water when desirable. Place 2 or 3 inches of rough cinders over the bottom above your tank, and if you use cocoa-nut fibre to plunge in, let the bottom of the pot rest on the cinders, not on the cocoa-nut fibre. By such a mode you can have top heat and bottom heat at will. It is next to impossible to cause heat to pass through cocoa-nut fibre when dry.

Arrangement of Plan (*G. P.*).—Write to Mr. J. Gibson, jun., Surrey Lane, Battersea, London, S.W., tell him what you require, and ask for what information you need.

Constructing an Ice-stack (*S. P.*).—The following is the plan adopted by the late Mr. Beaton. "It must be made sugar-loaf fashion, with the broad end at the bottom, of course. When the site is on level ground, the carts must be emptied so near to the cone that the ice when broken can be conveniently thrown on with shovels, and then two or even three places round the cone may be used for breaking the ice; but the easiest way is, when the ground or site is on the face of a bank, or at the bottom of a gravel or chalk pit, as in that way the carts may be emptied on the top of the bank, the ice broken there, and then thrown down the bank, so as to empty itself on the cone at once. At Shrubland a natural hollow was chosen for the site of the iceberg, and the bank on one side made steep; and at 6 feet from the bottom of the bank was the outside of the cone when it was finished. Some such space is necessary between the bank and the ice, to get rid of rain or snow-water running down the bank before it gets to the ice. At the bottom of the bank, and half way up, posts were let into the ground in pairs, 4 feet apart, and braced together with a strong piece of timber set across, as builders do their scaffolding; then the garden planks for wheeling on were made into a long trough, inclining from the top of the bank, and resting on these cross pieces; the bottom of the trough being carried out to near the centre of the cone, and far above it; the ice was broken on a platform of boards at the top of the bank, and thrown into the inclined trough, and it slid down just over the cone. A set of men were put on the cone to distribute the broken ice as it fell from the spout, and one of whom was the master builder: he saw the cone brought up regularly; and when the ice reached the height of the bottom of the spout, the planks were re-arranged so as to allow room for throwing off the ice as fast as it came down; and, finally, when the cone was finished into a sharp point, the whole was left till the first frost after mild or thawing weather; and the reason is this—As soon as it turns to rain or thaw, the ontside of the iceberg begins to melt a little, and sometimes it remains so for three weeks, but on the first hard frosty night the whole is frozen over again, and the outside of the cone is then as if it were one solid face of rugged ice; then is the time to thatch it with good long straw, and about the same thickness as you would a wheat or barley stack, and no more, provided you have cheaper materials to give it a good thick covering afterwards. At Shrubland they used large quantities of leaves, and nothing else, over the straw; throwing it on at intervals, so that the leaves did not heat by putting too many on at once. The depth of covering over the straw was sometimes twice as much as in other seasons, according to the quantity of leaves on hand, but 2 feet in thickness does not preserve the ice better than 1 foot. The ice was never uncovered by high winds blowing off the leaves, and never was anything put on or against them to keep them down. Perfect exemption from wet or damp is necessary for the bottom of an ice-heap; and a few pieces of rough wood, put on such a place, and covered with brushwood about 1 foot, and that again covered with 6 inches of straw, is the way. The brushwood and straw are soon compressed into a few inches in thickness by the weight of the ice; and as the ice melts, the water passes through, without hindrance, into cross open drains previously made at bottom."

Acacia Farnesiana.—"In 'Rimmel's Book of Perfumes' I have met with the following passage:—'Cassie (Acacia Farnesiana), is a shrub of the Acacia tribe, which only grows in southern latitudes. Its height ranges from 5 to 6 feet, and it becomes covered in the months of October and November with globular flowers of a bright golden hue, which peering through its delicate emerald foliage have the prettiest effect. All those who have travelled in that season on the coast of Genoa will no doubt remember what charming bouquets and garlands are made of the Cassie, intermixed with other flowers. To perfumes it is a most valuable assistant, possessing in the highest degree a fresh floral fragrance, which renders it highly useful in compounds. It bears some resemblance to the Violet, and being much stronger is often used to fortify that scent, which is naturally weak. The Cassie requires a very dry soil, well exposed to the sun's rays. The tree does not bear flowers until it is five or six years old. The yield varies from 1 lb. to 20 lbs. for every tree, according to age and position. The blossoms are gathered three times a-week, after sunrise; a very strong oil and pomade are obtained from them by maceration. In Africa, and principally in Tunis, an essential oil of Cassie is made, which is sold at about £4 per ounce, but French and Italian flowers are not sufficiently powerful to yield an essence.' Perhaps you or some of your correspondents may know the Acacia Farnesiana, and be able to testify as to the above description, which, if correct, sufficiently proves that this tree ought to be in more general cultivation, as in the months of October and November an elegant tree with bright golden flowers possessing the odour of Violets could not have many rivals.—E. T., *Packwood.* [Acacia Farnesiana is so called from being first introduced into Europe in the Farnese Gardens, which happened as long since as 1616. It is a native of St. Domingo, but is grown abundantly in Spain, Italy, and North Africa. It requires a warm greenhouse in this country.]

House Sewage (*D.*).—If the pipe conveying the sewage to the reservoir adjuts into a sieve, very little matter that cannot be pumped up will pass into the reservoir. What does subside to the bottom must be cleared out periodically. In our own experience such a reserveir did not need clearing out oftener than once a-year. By far the most valuable part of the sewage is that in the liquid form. We do not know Mr. Malins's experiments.

Accented Catalogue (*A. F. E.*). — Messrs. Carter & Co. have an accented catalogue, but that only includes annual, biennial, and perennial flowers raised from seed by gardeners.

Pruning Roses (*Alpha*).—Your trees being so recently planted we would not prune until the first mild weather after the middle of February, and then cut-in the shoots to within two or at most three eyes or buds of their base, cutting quite closely any weak shoots. The dwarfs you may treat in the same manner, leaving five buds below the cut on the very strong, three on the moderately strong, and one or two eyes on the weak shoots, cutting the very weak shoots away quite close to the stem. If any sheets are disposed to cross or crowd their neighbours cut them away, paying particular attention to the formation of a well-balanced open head.

Tacsonia ignea not Flowering (*Idem*).—The Tacsonia ignea and T. Devoniensis ought to have flowered in your greenhouse with bottom

heat, and we can only account for their not having done so from your keeping them in constant growth without affording a season of dryness or rest; or they may not have been trained sufficiently near the glass to afford the shoots a sufficiency of light and air, of which they can hardly have too much. Your Pomegranate out of doors will only succeed on a south aspect, and in a warm soil and sheltered situation. Both it and Tacsonia Devoniensis are tender.

Labels for Fruit Trees (*A. B.*).—The most enduring labels are those formed of lead with the names of the kinds of fruit tree impressed or indented with an iron stamp about halfway through the lead, which may be that known as 7 lbs. to the superficial foot. The labels should be 3 inches long, 1¼ wide, and have a hole through a shoulder left in the middle or one side of the label. The label should be fastened to the tree with stout flexible lead wire, allowing room for the tree to grow. You will require punch letters of the alphabet, and the figures correspondiog to that of the year in which the trees were planted, if you care to date their planting. Labels of this kind only perish with the lead. These are the most durable labels we know. Zinc labels are also good and last a long time, if the names of the trees be written on them with proper ink, which may be made of 1 drachm each of verdigris and sal ammoniac powder, ½ drachm lamp black, mixed with 10 drachms of water. The labels should be made bright by rubbing them with sand paper, then write the names upon them immediately in a clear bold hand with a quill pen.

Dipladenia and Allamanda Starting into Growth (*M. F.*).—You will now prune them, thinning out the weak and shortening the strong growths, and when the shoots have grown an inch or two pot the plants carefully, and encourage their growth by affording plenty of heat and moisture, but avoid making the soil very wet; in fact, be careful in respect to water until the plants recover the potting. Water sparingly until they are growing freely.

Pimelea decussata Treatment (*Idem*).—The plant now covered with young growth in your stove looking to the north, and being rather dark, should without further delay be removed into a light and airy situation in a greenhouse. The shoots you sent do not exhibit flower-buds, but it is too early to distinguish them. They may form flower-buds, and, if so, will most likely flower during May or June.

Newly Planted Peach Trees (*Nemo*).—Your wall being only 6 feet in height, it is certain you cannot want growth to any great extent. We would not, therefore, cut back the trees, but, having a sufficiency of shoots to cover the wall at 9 inches apart, train them at their full length, and in spring pinch the side shoots or take out their points at the third leaf, excepting any that may be required to train in to cover the wall, as already stated, with branches 9 inches apart All laterals after the first pinching should be stopped at the first leaf. If you propose to treat them on the long-pruning system, it may be necessary to head back the trees so as to furnish the requisite number of strong long shoots, and in that case the strong shoots may be cut back one-third and the moderately strong two-thirds their length, and you must make up your mind to wait two or three years for fruit; but by the first plan you will with proper care be sure of a crop the year after planting.

Camellia Buds Falling (*E. T.*).—We should think the buds fall from the want of proper support, and attribute it to the roots not being healthy, or at least inactive. The leaves are probably scorched through allowing the sun to shine powerfully upon them whilst wet and immature. It is not necessary to pot every year, once in three years is sufficient if the drainage is good. When making new growths they require an abundant supply of water, with heat, plenty of atmospheric moisture, and slight shade from bright sun. The soil should at all times be kept moist, no water being given until there are signs of dryness.

Amaryllis Adonis (*An Amateur*).—This will succeed "if started in a good bottom heat from the beginning of March to May." Gradually withdraw the plant from heat, moving it to a light warm greenhouse; there place it in the full sun, water plentifully for at least six weeks longer, and afterwards diminish the supply.

Ixias, Sparaxis, and Tulips under Hand-lights (*Idem*).—The pots of these, now that growth has commenced, may be removed to a light, airy, cool greenhouse, or to a cool part of a warm one, affording plenty of air; or you may leave them where they are, and protect with mats in severe weather, giving air when the temperature is mild.

Heating Hotbed (*Idem*).—By having a door made to fit closely at A, as shown in your sketch, you may prevent the heat escaping. You may keep up the heat by renewing the dung at each end alternately and frequently with hot well fermented material, and by keeping the space beneath full of the same.

Grafting Camellias (*Idem*).—Obtain stocks of the single red, and in spring, just before the plants begin to push afresh, whip-graft them just above the soil. After the graft has been made plunge the pots in a mild hotbed of from 70° to 75°, and cover with a bell-glass, hand-glass, or close-fitting frame, in addition to the outer glass covering of the house, keeping close until the grafts commence growth, then admit air by degrees. Full directions for grafting are given in "Fruit Gardening for the Many," which you can have free by post from our office, if you enclose five postage stamps with your direction.

Vinery (*One in Perplexity*).—In the house 50 feet long by 12 wide, in which you have three Peach trees and a Vine against the back wall, there is nothing to prevent your having these trees in a cool house, and a Vine up the rafters at every 4 feet, but you must restrict these Vines to close spur-pruning, and not allow the bearing laterals to extend too far from the stem, for just in proportion to your shading the roof with Vines will you darken and injure the trees on the back wall. If you divide the house into two, and have a stove in one end, that end will come in before the other, and thus give you a succession, a matter of importance as respects the Peaches. The inside border will do for the Vines, but you must top-dress it well every year. If you left two or three of the rafters vacant it would be all the better for the back wall. If you value the Vines most, then plant against each rafter. For such a house, Black Hamburgh, Esperione, Royal Muscadine, and Buckland Sweetwater, will answer well.

Extent of Piping a Boiler will Heat (*Excelsior*).—We should judge such a boiler, surrounding a furnace 18 inches by 24, would heat from 250 to 300 feet of four-inch piping, but much would depend on the working. We do not exactly perceive the importance of the sixteen tubes, 6 inches by 1½ at the top, through which the fire passes to the flue. Are these tubes for air and smoke, or are they for water, and the smoke to get to the flue between them? The feeding-door being beneath these pipes leaves us in doubt. The boiler complete, without brickwork, is an advantage, but unless the boiler be inside, with merely the feeding-doors outside the house, much heat will be lost, especially if the boiler is not protected at the sides by a non-radiating, non-conducting material, as has several times been recommended for such boilers. To obtain the most heat and no dust, the boiler should be inside the house, and the feeding-door, ashpit, &c., outside.

Planting Strawberries (*C. W.*).—The ground you intend to plant with Strawberries should at once be trenched to a depth of 2 feet, or as deep as the soil allows. Too much of the subsoil, if it is sand, gravel, or clay, must not be brought to the surface, though a few inches may do no harm. If there be turf on the ground place it at the bottom, and unless the soil is light no further manuring will be required, but if it is light and poor apply a good dressing of cowdung, and place it a foot or 18 inches from the surface. It would be well if the soil is heavy to throw it up in ridges, and being exposed to frost and air it will be the easier worked, and more suitable for the plants. Choose a time when the ground is in good working order during March to plant the runners of last year, moving them with a ball of earth to each. Spring is the best time to plant Strawberries.

Soil for Camellias and Azaleas (*Senex*).—Camellias do best in a compost of turfy loam formed by cutting turf from a pasture where the soil is neither very light nor very heavy, but a good medium-textured, hazel or yellow loam. Cut it 3 inches thick, and place it in an open situation, grass-side downwards, with a layer of cowdung an inch thick between each layer of turves. At the end of six months turn the heap over, and again three months afterwards, and at the end of twelve months the soil will be fit to take under cover, and being chopped up with a spade it constitutes the best compost we know for Camellias. Failing this, two-thirds loam, if turfy all the better, and one-third peat, with a free admixture of sand, will grow them well, but not equal to the former compost. If the loam is poor and not turfy, you may add one-fourth of your well-rotted dung; the little old mortar there is in it will do no harm. The Azaleas should have a compost of two-thirds sandy, turfy peat, and one-third turfy loam, adding one-sixth of silver sand. Azaleas do not require manure. Both Camellias and Azaleas require the pots well drained.

Nitrate of Soda (*Bexley*).—One dressing of nitrate of soda for a lawn is sufficient for one season.

Caterpillars on Quickset Hedge (*Idem*).—Syringe the hedges in the evening with a solution of 2 lbs. of soft soap, and one peck of lime in thirty gallons of water, straining the solution so that dirt may not clog the syringe; or after a shower strew newly slacked lime over the hedges.

Peach Trees Infested with Scale (*Anxious*).—We sympathise with you, but cannot believe that the use of the composition named at page 78 of No. 226, Vol. IX., would cause the mischief you complain of, for we have employed it many times before and since that time for dressing Peach and other fruit trees without the loss of a single fruit-bud, or injury to a branch or shoot. We fear the brush has been used with no light hand, and been rubbed up and down as in painting woodwork, which would, to a certainty, disturb the buds. The brush should have been used gently, taking proper care not to disturb the buds. The wood, you say, is dried up. None of the ingredients of the composition will destroy the wood of any deciduous smooth-barked trees, and how it could penetrate through the scales of the buds we do not know, unless they had begun to swell before the application of the composition. Either the latter was applied at a higher temperature than 140°, or the trees were so much infested with scale (which you state rendered them unsightly in growth), that the shoots were exhausted. Irrespective of any harm from the application of the composition, we do not think you have any hopes of a crop of fruit this year. You must now wait and see the result of the swelling of the buds, and the commencement of new growth; and should the buds fall, as we apprehend they will do to a great extent under any circumstances, cut away the shoots that should have borne to within half an inch of the lowest new shoot, and train that in the place of the shoot cut away. An attack of scale, such as your trees appear to have suffered from, was more than sufficient to have caused the evils of which you complain.

Heating by Hot Water (*Jardinier*).—We do not understand your case thoroughly, because you do not state where your steam-pipe was placed, where your supply-box is situated, or whether it communicates with the top or the bottom of the boiler; and, again, the exact position of this supply-box is also a mystery, since it is described as being 2 feet above the boiler, and, again, 3 feet above the highest point of the pipes. Now, first, with the supply-box so much higher than the highest point of the pipes, in order to prevent this boiling over, we would change the tap into an open gas-pipe, going out of the house, and at a height of several feet above the supply-box. Then, if this did not answer, you would have either to make your supply-box larger, or add another one at the same height, to communicate by a lengthened tap-pipe with the highest point in the pipes of the house. Your trouble of boiling over arises from the power of the boiler to heat five times the quantity of piping, the size of your supply-box being insufficient for the rapid exhaustion of greatly heating the water. Your house would have been better heated with more piping. By taking the air-pipe from the tap, as proposed, out of the house, and, say fully 6 feet above the water-pipe, reversing its end ⌐, putting on merely enough of fire to heat the same 80 feet of piping, and banking up and using the damper, then we think the boiler may be used without boiling over.

Sugar-baker's Skimming (*M. T. Smith*).—It has been frequently applied to Vines and other fruit trees which required manuring. Its fertilising qualities are chiefly owing to the ox blood used for clarifying the syrup. We never heard of its employment as a liquid manure, and do not think it would dissolve.

Names of Fruits (*Umpire*).—*Apples:* 1, Court of Wick; 3, Sykehouse Russet; 4, Biggs' Nonsuch; 5, Autumn Pearmain. *Pears:* 2, Beurré Dercuineau; 3, Swan's Egg; 4, Zephirin Grégoire. (*W. H. S.*).—Your Pear is St. Lezin.

Names of Plants (*J. C. M.*).—A Maxillaria most likely; but too far gone when received for identification. (*E. M. Buck*).—1, Cheilanthes myriophylla; 2, Pellæa hastata (?); 3, Selaginella hortensia; 4, Blechnum sp. (?); 5, Onychium japonicum; 6, Asplenium dimorphum. (*C. T. F.*).—We will give the name and particulars of your Solanum next week.

METEOROLOGICAL OBSERVATIONS in the Suburbs of London for the Week ending January 12th.

Date.	Barometer.		Thermometer. Air.		Thermometer. Earth.		Wind.	Rain in inches.	General Remarks.
	Max.	Min.	Max.	Min.	1 ft. dp.	2 ft. dp.			
Sun... 6	29.378	29.336	49	30	40	40	S.E.	.00	Hazy, with slight rain; fine and rather mild.
Mon... 7	29.230	29.026	53	44	35	40	S.W.	.46	Overcast; hazy; rain; fine at night.
Tues. . 8	29.760	29.760	52	36	40	42	S.W.	.01	Rain; snow rapidly disappearing; very boisterous.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

MUTILATING A COMPETITOR'S FOWLS.

From circumstances that have recently come within my personal cognisance, coupled with the perusal of the letter of Mr. Charles Sidgwick, of Ryddlesden Hall, Keighley, inserted in last week's Journal, I much fear the dastardly practice of plucking out the sickle feathers of exhibition fowls, unless prompt measures are adopted for its prevention, is about to be recommenced. About two years ago it was a continually recurring nuisance, and was then perpetrated generally at exhibitions after the awards were returned, and in several instances even before the prize cards were affixed to the pens. I have repeatedly awarded prizes to full-tailed cocks, and been astounded afterwards, within a very brief space of time, to find the tails more or less spoiled by wilfully plucking two or more of the principal feathers. It must be borne in mind, that not only does this unmanly practice prevent the possibility of exhibition for several weeks, but, what is far more discouraging to owners, the chances are seriously against the new feathers proving true to colour when reproduced after this violent and unnatural extraction of the original plumage. In every case I can call to mind the abstracted feathers were found lying either behind some of the adjacent pens, or thrown away at some distauce on the show-field. As they were never carried away it was evident they were not taken for profit, but from a spirit of mischief or some far more decidedly worse motive. From the simple fact that a party, of course nameless, never met with this accident (?) when the poultry under his care were successful, but repeatedly such mutilations of first-prize birds took place when his competing pens were defeated, a stroug suspicion was aroused, and a very vigilant surveillance ensued. Detection did not follow, but an officer in plain clothes, who had been on the watch, stated much to confirm suspicions; the only good was, that from that time until quite recently no repetition whatever of this cowardly act took place. Now, as I am informed that the law can be strictly enforced against any one convicted of committing such wilful damage, I suggest to all parties interested to be on the alert, and if possible place the offender, whoever he may prove to be, within the gripe of the law. I do not suggest to others what I should hesitate to do myself, for I purpose following out to the letter the advice laid down, and should this prove effective, so much the better; but if a general effort only prevents the recurrence of this abominable mutilation of valuable property, surely my present letter may not be written in vain. I do heartily wish you would give the poultry-loving world your opinions on the subject.—Edward Hewitt, *Eden Cottage, Sparkbrook, Birmingham.*

[This letter needs no support—the offence it denounces must be abhorrent to every honourable mind. We hope that the Committees of Poultry Shows will be on the alert to detect such criminals. Men placed to watch the pens might prevent the perpetration of the offence, or might detect the perpetrator. If detected, let him be unflinchingly prosecuted, and we promise to publish his name with such particulars as will hold him up to scorn and execration. One name from the north has been forwarded to us, but the evidence is not sufficient to justify its publication.—Eds.]

A GOOD INTENTION.

I am a working man with but little cash above the wants of my family, but I have a large garden, and I can make some pens at a small cost to contain a few fowls, the produce of which, I think, as food for my family, will repay the cost of their keep, and I shall have the pleasure of a few pets to look after. I therefore intend laying down a small portion of my garden in grass for a run for the chickens; but when I have done all this my difficulties begin, for I am not a judge of the feathered tribe, and, therefore, I cannot select my stock; at the same time my circumstances will not allow me to buy my stock from the head breeders as I would otherwise do. I write, therefore, to ask you to name some one from whom I can obtain fowls at a reasonable rate, yet at the same time useful stock.

As to the sorts, I think the evidence is in favour of Dark Brahmas: therefore I will say (subject to your approval), a few of these, a few of Black Spanish, which I think are a noble fowl, and their eggs certainly look noble on the breakfast-table, and a few Buff Cochins to run in a backyard, which I am afraid is too confined for any other fowls.

I must apologise for the trouble I am giving; but, let me add, it is not only on my own account, but for several of my fellow workmen who wish to keep a few fowls. They, like myself, wish to obtain something better than the old Barndoor fowl, believing, as I do, the best kinds are the best to keep.—Inquirer.

[We insert this letter because we think that some of our readers who have surplus stocks of the varieties named by "Inquirer" may be willing to let him and his fellow workmen have them at the market-rate for table-fowls. We mean birds that for some defect would not be saleable to poultry fanciers. Should not any such offer reach us, then we recommend "Inquirer" and his fellow workmen to depute one of their number to attend a sale at Mr. Stevens's Auction Rooms, King Street, Covent Garden. When such a sale of poultry is advertised in our columns, if "Inquirer" writes to Mr. Stevens he would send a catalogue, and then "Inquirer" would see whether the poultry to be sold were such as he and the others need.—Eds.]

THE LATE TREASURER OF THE POULTRY CLUB.

Referring to Mr. Tudman's communication, which appears in your impression of last week, I must remind Mr. Tudman, once for all, that he had due notice that he would be called on for an explanation of his conduct by resolution at Birmingham before the general meeting of the Poultry Club; that he shrunk from and evaded that explanation by resigning his office as Treasurer, and retiring before the resolution could be brought on, being probably perfectly aware that I had personal and documentary evidence on the spot to substantiate any assertions I might make, many of the latter being in Mr. Tudman's own handwriting. These are still at my command, and I adhere to and re-assert all the statements I made in your Journal of the 1st inst.; and as Mr. Tudman did not choose to avail himself of the legitimate means offered him of clearing himself, I certainly, no matter what his assertions may be, shall decline to continue this correspondence, being quite content to leave the members of the Club and the public at large to draw their own inferences.—F. W. Zurhorst, *Hon. Sec. Poultry Club.*

LEEDS POULTRY SHOW.

I find in your last Number, page 34, two complaints respecting my opinions about the Leeds Poultry Show, one from a correspondent signing "Black Bantam," and the other "J. W."

Certainly Black Bantams should have black legs and not puckered earlobes, such as "Black Bantam" has seen disqualified at many previous exhibitions. Well, so far so good; but I suppose we do not end with an idea, that because one pen is better in the colour of the legs, and to "Black Bantam's" fancy better in the earlobes, that he ought to have won. I trust, however, that "Black Bantam" will grant me as much forbearance as he seems to have towards the Judges, and that I may be exonerated from blame, as on the Leeds Show day I expressed my opinion against him, and although we did not then agree, we parted good friends, and as such I trust we shall continue. Still, I must tell "Black Bantam" honestly, that in my estimation his birds were beaten at Leeds by the pen he condemns as having flesh-coloured legs and puckered earlobes, and if he will look at his own pens I will read him their faults from memory, and for which I vouch.

The cock which "Black Bantam" had in his pen has the most disagreeable comb I ever saw in a pen to win a Birmingham prize; it is large, tall, clumsy, and at the top, where it ought to be serrated, it is neither like a comb nor approaching one, and I heard a friend of "Black Bantam's" say it was like a piece of pudding batter. The hens were small and good, "if,"—if what? why, they had been healthy; but they were in such a bad state, that I trust "Black Bantam" will require me to say no more on this subject. Perhaps he will ask, Where was he beaten after all? Well, in the comb of the cock, the plumage of the pen, and the health of the birds. These, in my estimation, were the points which carried the honours to the pen which contained a cock with lightish-coloured legs, but in every other point a pen difficult to excel; and had "Black Bantam" judged without prejudice, he would, in my estimation, not have dwelt so long on the puckered earlobes, as he calls them, as there was very little difference in that respect betwixt the first-prize pen and his own. Having stated my opinion so candidly in this case, I must only add that I have not the slightest desire to offend one for whom I have a strong feeling of friendship.

Next for "J. W." If he will read my remarks on the Hamburgh cup pen he will see that though I differed from the knowing ones, yet at the time I honestly quoted their opinions. —J. D. Newsome.

DOTTINGS AT THE BRISTOL AND CLIFTON POULTRY SHOW.

For some weeks past the west of England has been invaded by huge placards advertising this Show. These placards have not been headed by ungainly Cochins, as is generally the case—and by the word "ungainly" I do not refer to the breed, but to the representations—but by very respectable portraits of white-faced Spanish fowls. This, at least, is appropriate, for is there any part of England or the world that can cope with dirty Bristol in this aristocratic breed? Sorely, if Dorking was right in holding a show for Dorkings only, Bristol might thus have acted in reference to Spanish; but wiser counsels ruled. Still, it is an interesting poultry speculation to discover why Bristol and Spanish are inseparable; why the best exhibitors and the greatest prizetakers should have congregated at Bristol—in early "mania" days Rake and Plummer, the latter sweeping first, second, and third prizes for chickens at the first Worcester Show, and then, as if satisfied, retiring from the fancy; these quickly followed by Rodhard, and now Lane, Jones, Parsley, Rone, and others, till, in a poultry sense, Bristol may be called the capital of the Spanish country. Time was when a darkened house was thought to improve the white face. Well; at Bristol it is nearly always dark! So far, if this theory is still held, Bristol atmosphere is in favour of first-rate Spanish. Be this as it may, whatever the local advantages may be, Bristol people, who, in my boyhood's days were said "to sleep with one eye open," know how to take advantage of them.

Whatever may be the faith of other parts of the country in the great Game critic of our Journal, Bristol has no faith in "Newmarket," and evidently believes in the beauty of the Spaniard rather than of the Game; and so long as they can show us such Spanish as appeared at the Bristol Show, so long may they retain their preference.

Doubtless, it has often been a mystery to poultry-breeders, and especially to us southrons, why, with many local prizetakers in Bristol and its environs, with a teeming population in addition, Bristol should be without a poultry exhibition. "A burnt child dreads the fire," proverbs tell us; perhaps this explains it. Many years ago Bristol held an exhibition. I think it was the first place where Mr. Rake exhibited his strain, which he had kept many years without knowing their real value; he was at the head of the chicken class. This show was, I believe, the starting-point of his triumphs. Alas! like many other attempts, I fear, this show was not a success. Nothing daunted, two or three years later Bristol essayed again, this time at the Zoological Gardens, but again, I fear, in a pecuniary point of view it was a failure. I recollect well going once to see that show, and feeling convinced that the influx of visitors could not possibly pay—there was no difficulty in seeing any pen you pleased, the fact being, as I believe, that the Gardens were too far away from the town. For many years, then, matters have remained dormant, and Bristol men have been content to reap their triumphs abroad instead of at home. The autumn of 1866, however, brought whispers of a poultry exhibition; but the first-born, and let us hope not the only child, was to be no puny bantling, but one that should at starting boldly challenge any of its older rivals for liberality of prize list and accompanying excellence of specimens. The appearance of the prize list satisfied the first; some one or two minor points might be wisely amended, but the prize list was eminently liberal. As regards the second point, any connoisseur who visited the Exhibition would allow that the eight hundred pens formed a splendid collection of domestic poultry. It may, I think, be safely affirmed that never in the western counties has so valuable a collection of birds been brought together.

Let us, however, take the prize list. *Spanish*, of course, were first-class. Never, perhaps, has a better collection been seen; but every prize, whether in the adult, chicken, or single cock class, was taken by Bristolians. Bravo, Bristol! In the chicken class were twelve highly commended pens! The show of these birds was magnificent. The second-prize single cock was a most splendid bird; but, unfortunately, had one side of the face disfigured, or he must have taken the cup. Mr. Parsley's cup chickens were also most excellent; and the other prize pens, with Mr. E. Jones's very highly commended pen, were only behind because they could not all be first.

Dorkings formed a large entry; but as far as one can gather, not a first-rate collection. In the chickens not a single commendation was awarded amongst thirty pens! The old birds contained the pen that the Judges considered the gem of the Exhibition, to which Mr. Lang's ten-guinea cup was awarded. I am no Dorking breeder, and possibly know nothing of Dorkings; but I liked Lady Holmesdale's second-prize pen better than this her cup pen. I examined it closely. The local papers said it was owing to the particularly "clean condition of the legs" that it obtained its position. The legs were clean certainly, the scales looked soft, but the cock was deficient, as it appeared to me, in the proper Dorking fifth claw. This I had always imagined should be distinct, standing out from the other toes, and generally from 2 to 3 inches long. If this be correct, then the bird failed here, for the claw was certainly not 2 inches long, and this claw seemed rather to have an inclination for the fourth, and somewhat to follow its course. The comb of the cock was large, and certainly twisted. Lastly, one of the hens had a much smaller comb than the other, and, instead of falling over, it twisted, but remained erect—at least, so it appeared to me and to many, who examined the pen closely. They were certainly very heavy birds. The third-prize birds were large, but the cock was duck-footed, and one of the hens inclined to the same defect.

The *Cochins* were a grand array of birds, especially the Brown birds, some of these being magnificent specimens. Mr. Fenton's cup hens appeared too fat to me, and they were dull and heavy in the pen. With my *penchant* for a moderate vulture hock, my delight was great at seeing many birds in these classes prizetakers, with unmistakeable vulture hocks. Mr. J. Cattell's third-prize Buffs were even a shade beyond what I like—at least, the cock was. The cup chicken birds had also well-covered hocks, which added greatly to their beauty; so had several of the highly-commended pens in all the varieties.

I cannot sufficiently express my satisfaction at seeing these adjudications, the more so, as when I came to examine my favourites the *Brahmas*, there was unmistakeable evidence of the mischief that the fear of the vulture-hock disqualification had produced in legs absolutely with feathers as far apart as the raisins in my grandmother's pudding. Numbers of the pens shown were positively deficient in leg feathers. Mr. Boyle's cup birds were beautiful in condition; good in all respects. They were, however, in my humble opinion, closely pressed by an unnoticed pen, belonging to Mr. Lacy, that contained two magnificent hens, only one of them was, I imagine, too old and too fat, and the hinder parts often seemed on the ground. The second-prize birds had nothing to recommend them that I could see. The third-prize cock was wretchedly feathered. A pen from the Rev. W. J. Mellor deserved, but did not obtain commendation. So much for the adult Dark birds. Passing to chickens, I did not see a good pen there, to my fancy. The first-prize birds were coarse-combed and poorly feathered. Mr. Boyle's second-prize was better, but the pullets did not match on the breast. In one respect there was a general improvement—viz., the bronzing of the wing; this was far less visible. In Light birds Mr. Parea had it almost his own way, in spite of his sad loss through railway tender mercies, for which I heartily trust the company will suffer. I cannot say that I liked these birds; generally the poorness of leg-feathering was lamentable. One of the chicken pens that was awarded the third prize was claimed for Her Majesty the Queen, at £50! The single cock class contained the gem of the Brahmas in Mr. Boyle's first-prize bird. He left nothing for me to desire—heavily feathered, short-legged, splendid black breast, evenly spotted, and faultless condition. The rest of the noticed birds in this class were wretched.

Malays.—Yes, to be sure, Bristol had a class for them, and by several it was not the smallest class in the Show. The cock exhibited by Mr. Cooper was a beautiful bird; the hens very poor. The cock shown by Mr. Brooke was a very good-coloured bird.

Of *Crève Cœurs* there was a good entry; but why not Black Polands?

There was a cock in the Poland class that would have made a very respectable Crève Cœur. Mr. Blinkhorn's birds were large and massive-framed.

Game constituted an exhibition in itself; but as I have neither the head-piece, nor the eye, nor the pen of "NEWMARKET," I shall only say that the contest for Mr. Laing's cup was said to be between Lady Holmesdale's Dorkings, Mr. J. Fletcher's Game, and Mr. Parsley's young Spanish; that the latter was first disposed of, then the Game. I could detect no fault in this beautiful pen, whilst condition was faultless. Setting aside that the difficulty of showing a pair of hens is much beyond that of a single hen, I must give my verdict for the Game pen. Mr. J. Fletcher headed all the Game classes for cock and hen.

The *Hamburgh* classes were well filled, and contained beautiful birds. The Silver-spangled are my favourites. The tails seem perfect, but surely the bar on the wing is less marked than in former years. Black Hamburghs had some faces pale with rage at being unnoticed, or else from their Spanish ancestors!

Polands were indeed a splendid class, nine pens out of fifteen entries being noticed. The Silvers were especially good. These birds formed, to my mind, one of the great beauties of the Exhibition, and I trust another year they will be divided into several classes.

In the Any other variety class the first prize went to very large La Flèche. The cock, I should think, was among the heavy birds of the Exhibition.

Bantams, beautiful little pets, and in their own estimation by no means the least important. Mr. Kelleway's cup birds I thought exquisite. I cannot say that I fancied the first-prize single cock Game; he was certainly in splendid fettle, but his wings nearly raked the ground.

The *Ducks*, *Geese*, and *Turkeys* were no mean part of this Exhibition. There was in the Any other variety of Ducks a lovely pair of small Ducks, quite one of the gems of the collection, but what they were I cannot say; and this brings me to one of the mistakes of the Exhibition. The catalogue contained no names of the varieties in the Any other variety classes, so that the uninitiated were perfectly at a loss when examining them.

From various causes there were many empty pens; they were useful in separating specimens. It appeared to me that in this respect the Committee were rather unfortunate, several bleeding combs being noticeable. The Dorking single cocks were in pens decidedly too small. These minor matters, inseparable from the most careful arrangements, were the only drawbacks. No praise is sufficient for the labours of those gentlemen who have been instrumental in providing the west of England with such a treat. May their shadows never be less! and may this experiment prove thoroughly successful, and establish on a firm basis the Bristol and Clifton Poultry Show. The Rifle Drill Hall is perfection—beautifully lighted, equable in temperature, tastefully decorated, and free from smell.

And here I close my doings with a well earned "thank you" to the Committee for such a sight; and when they next invite their friends, as I trust they will, may my birds be there to crow and I to see.—Y. B. A. Z.

KIRKCALDY POULTRY SHOW.

THE annual Show of the Fife and Kinross Society was held at Kirkcaldy on the 7th and 8th inst. There were upwards of 140 entries for Poultry, about 20 of Pigeons, and nearly 100 of Canaries.

The *Game* fowls were much superior to those exhibited in any previous year. *Dorkings* were also very good. Of *Hamburghs*, there was likewise a good show. The Silver-spangled were much admired.

Pigeons were good.

GAME.—*Cock.*—First, A. Spalding, Raith. Second, J. M'Gregor, Crieff. Third, J. Lyall, Kirkcaldy. Highly Commended, H. Goodall, Kirkcaldy. Commended, J. Crombie, Leslie.

GAME (Reds).—First, C. Jamieson, Forfar. Second, T. Baird, Auchtertool. Third, A. Speed, Leslie. Highly Commended, A. Haggart, Leslie. Commended, R. Stewart, Kelty. *Chickens.*—First, C. Jamieson. Second, R. Stewart. Third, H. Goodall.

GAME (Grey).—First, J. Fisher, Kirkcaldy. Second, T. Williamson, Kirkcaldy. Commended, C Jamieson. *Chickens.*—First, A. Speed. Second, H. Goodall. Third, J. Penman, Boreland, Dysart. Commended, J. Chapman, Kirkcaldy.

DORKING (Any variety).—*Cock.*—First and Second, Countess de Flahault, Tullyallan Castle. Third, D. Raines, Bridge Haugh, Stirling. Highly Commended, Countess de Flahault. Commended, D. Normand, Kennoway.

DORKING.—*Chickens.*—First and Second, Countess de Flahault. Third, D. Gellatly, Meigle. Highly Commended, Countess de Flahault.

COCHIN.—*Cock.*—First and Second, Mrs. Oswald, Dunnikier. Third, Earl of Rosslyn, Dysart. Commended, H. Terris, Kelty

COCHIN-CHINA (Any variety).—First and Third, Mrs. Oswald. Second, W. R. Park, Melrose. Commended, H. Terris

BRAHMA POOTRA (Any variety).—First and Second, K. Jopp, Aberdeen. Third, D. Annan, Torr of Moonzie, Cupar, var. Commended, H. Terris.

SPANISH.—First, R. Dickson, Kirkcaldy. Second, J. Beveridge, Kirkcaldy. Third, W. Roberston, Dunfermline. Commended, J. Michie, Wemyss Castle.

HAMBURGH.—*Cock.*—First, R. Hunter, Blairadam. Second, H. Goodall. Third, G. Penman, Prinlaws. Commended, A. Pratt, Kirkcaldy.

HAMBURGH (Spangled).—First, W. Keddie, Cowdonheath. Second, R. Stewart, Kelty. Third, D. Stevenson, Cowdenbeath. Commended, A. Hutton.

HAMBURGH (Pencilled).—First, J. Watson, St. Clairtown. Second, D. Normand. Third, J. Morrison, Alloa.

GAME BANTAMS.—First, A. C. Brown, New Scone, Perth. Second, A. Robertson, Burntisland. Third, H. Anderson, jun., Chapel House.

BANTAMS.—First, A. C. Brown. Second, J. Ness, St. Clairtown. Third, G. Penman.

ANY OTHER BREED.—First, Second, and Commended, Countess de Flahault (La Flèche, Houdan, Crève Cœur). Third, W. R. Park (Crève Cœur).

SELLING CLASS.—First, D. Normand (Dorkings). Second, R. Stewart (Black Red Game).

BANTAM.—*Cock.*—First, J. Young, Kirkcaldy. Second, A. Robertson. Third, A. C. Brown.

DUCKS (Any breed).—First, A. Haggart, Leslie. Second, A. Couper, Dunfermline. Third, A. Spalding.

PIGEONS.

TUMBLERS.—First, J. E. Spence, Musselburgh. Second and Third, J Robertson, St. Clairtown.

FANTAILS.—First, W. R. Park. Second, J. E. Spence. Third, G. Laing, Kirkcaldy.

NUNS.—First, W. R. Park. Second, J. Bogie, Wemyss. Third, R. B. Heggie, Kirkcaldy.

ANY OTHER VARIETY.—First, Countess de Flahault (Jacobins). Second, J. E. Spence (Powters). Third, R. B. Heggie (Barbs).

CANARIES.

SCOTCH FANCY (Yellow).—*Cocks.*—First, G. Binnie, Perth. Second and Third, W. Bonthron, Kirkcaldy. *Hens.*—First, J. Kemp, Galashiels. Second, G. Binnie. Third and Fourth, J Sime, Dunfermline.

SCOTCH FANCY (Buff).—*Cocks.*—First, G. Binnie. Second, J. Mitchell, Third, J. Morrison. Fourth, J. Herdsman, Kirkcaldy. *Hens.*—First and Third, R. Hunter, Oakley. Second, W. Bonthron. Fourth, J. Bennet.

BELGIAN FANCY (Yellow).—*Cocks.*—First, T. Sidey, Dunfermline. Second, J. Cleghorn. Third, T. Kerr, Edinburgh. Fourth, J. Bennet. *Hens.*—First, J. Kemp. Second, T. Sidey. Third, W. Tinlin, Galashiels. Fourth, W. Pitcaithly.

BELGIAN (Buff).—*Cocks.*—First, T. Sidey. Second, J. Kemp. Third, J. Bennet. *Hens.*—First, J. Cleghorn. Second, J. Kemp. Third, W. Tinlin. Fourth, W. Pitcaithley.

FLECKED FANCY (Yellow).—*Cocks.*—First, T. Kerr. Second, G. Spence. *Hens.*—First, W. Bonthron. Second and Fourth, R. Hunter. Third, J. Gardener.

FLECKED FANCY (Buff).—*Cocks.*—First, R. Hunter. Second, J. Gardner. Third, A. Fleming, Dysart. *Hens.*—First, J. Morrison. Second, R. Hunter. Third and Fourth, J. Herdsman, Kirkcaldy.

GOLDFINCH MULES (Marked, Yellow).—*Cocks.*—First, J. Robertson, Aberdour. Second and Third, W. Kirk.

GOLDFINCH MULES (Marked, Buff.—First, A. Fleming. Second, Third, and Fourth, W. Kirk.

SELLING CLASS (Any variety).—First and Second, Mrs. Wilson (Yellow Flecked and Buff Hen). Third, A. Clark (Buff Cock).

JUDGES.—*Poultry:* Mr. Anderson, Ruthven House. *Pigeons and Canaries:* Mr. A. Stewart, Perth; Mr. Thomas Haddow, Glasgow.

NEWCASTLE-ON-TYNE COLUMBARIAN SOCIETY.

THE second annual Exhibition of this Society was held on the 1st inst., in a very commodious room at the Phœnix Inn, Newgate Street, Newcastle-on-Tyne.

The Show was confined to members, and only for birds bred during the year, but the Exhibition was open to the public at 6*d.* each admission. The pens were "home-made," all on a level, and, considering circumstances, answered the purpose well.

The birds were both numerous and good, especially Short-faced Tumblers and Fantails. The first prize for Almonds was awarded to a first-class head-and-beak cock with fine carriage and good eye, but deficient in colour; the second went to a promising hen of good colour, but not equal in other properties. Several other good Almonds were worthy of notice, and there is a great improvement in Short-faced Tumblers in this district. In the class for Any other variety of Short-faced birds, the first prize was taken by a fine Red Mottle, and the second by a good Kite. The class also contained a good Dun. Powters were numerous, being fair average birds (Ash cock first, and Red hen second). Some promising Blues also competed. Carriers were not so good; the prize birds showed a little style, but were weedy and light in beak. Barbs were poor. Owls were rather numerous, and were of the old English Blue variety. The prize pair were small and good of their kind. In Trumpeters the class was only small; the first prize was awarded to a fair average Black. In Jacobins, a pair of small Reds were unmistakeably the winners. Some Yellows were shown in capital condition, but were large and coarse. Turbits formed a very good class. A pair of good Swallows were exhibited, one of which took an extra prize for the best Toy in the Show. The prize Nuns and Magpies were good. Fantails were a very creditable collection, the prizetakers (cock and hen) ought to go together, and would undoubtedly hold a prominent position at some of our best Shows.

We would suggest that in future there should be separate classes for cocks and hens, instead of allowing them to compete together; it would be much more satisfactory and give all an equal chance.

We wish the Society every success, and trust that the next Show will far exceed the present one.

TUMBLERS (Almond, Short-faced).—First, T. Thompson, Wide Open. Second, W. Petre, Felling.

SELF-COLOURED TUMBLERS (Short-faced).—First, W. Petre. Second, R. Daniels, Newcastle-on-Tyne.

Powters (Any colour).—First and Second, T. Thompson.
Carriers.—First and Second, N. Stephenson, High Felling.
Barbs.—First, R. Daniels. Second, W. Petre.
Trumpeters.—First, J Bell, Newcastle-on-Tyne. Second, R. Daniels.
Turbits —First, W. Byers, Seaton Sluce. Second, H. Morrow, Carrus Hill.
Jacobins.—First, C. Vaux, Sunderland Second, R. Daniels.
Fantails.—First, R. Fawdon, Gateshead. Second, R Daniels.
Owls.—First, W. Brown, Low Fell. Second, R. Fawdon.
Nuns.—First and Second, J. Bell, Newcastle.
Tumblers (Almond, Coloured).—First and Second, R. Fawdon.
Tumblers (Yellow).—First and Second, P. Stephenson.
Bald Head.—First, H. Morrow. Second, P. Stephenson.
Beards.—First and Second, W. Petre.
Dragons.—First, R. Fawdon. Second, P. Stephenson.
Antwerps.—First and Second, J. Bell.
Swallows —First and Second, W. Byers.
Blue Rocks.—First and Second, H. Wardle, Newcastle.

Mr. J. R. Robinson, of Sunderland, officiated as Judge, and his awards gave general satisfaction.

THE WHITEHAVEN POULTRY AND PIGEON SHOW.

This year's Show proved an exceedingly good one; in fact, whilst the quality and condition of the birds manifested a very great improvement, there were considerably more than a hundred entries beyond those of any preceding year. This fact, though augurring well for the stability of the Whitehaven Show, seems rather to have taken the Committee by surprise, and necessitated an arrangement of the pens that was not so efficient as it otherwise might have been, causing many of the bottom pens to be placed so low that inspection of any kind was a work of considerable difficulty, as they rested on the ground itself, whilst a great portion of the Game cocks was, as being in the third tier, placed far above the heads of the majority of spectators. This unexpected increase in numbers had, of course, to be immediately provided for as the Committee best could, but we are told that that body purpose in future years to make an improved arrangement of the pens, by which the light—by no means too much, under the most favourable circumstances, and this year increased by the disadvantage of a very dull cloudy day—will be no longer impeded. It would be well, too, whilst these alterations are under consideration, to increase both the height and the depth, from back to front, of the Pigeon pens, as they are not sufficiently large for the birds to turn without injury to their plumage. There might also be an improvement in another department of the Exhibition, for under present plans the show of eggs, which certainly seems a very popular part of the Exhibition, enjoys the very best of lights in the whole Riding School, and which would be much better appropriated to the best of the varieties of poultry. We cannot, however, do otherwise than congratulate the Committee on the general success of the undertaking; and the progressive manner in which for nine years this Show has been now carried on, affords great encouragement to renewed exertions.

As *Game* classes are first on the Whitehaven list, we refer to them accordingly. In these classes, Mr. Fletcher, of Stoneclough, near Manchester, had the almost exclusive possession of the highest positions on the prize list. It is certain a long time has elapsed since so perfect a collection of Game fowls of all varieties has been exhibited by any single individual. The manner in which they were selected for the Show, and the extraordinarily good condition in which every pen of this gentleman's fowls was shown, cannot be too highly praised They had obviously been under very experienced management, and these birds were evidently at the very moment quite as ready and willing to support their claim in the cock-pit itself, as they had been in the exhibition-pen. The competition in all the Game classes was far greater than usual, the liberal prize list causing great rivalry. We always like to see the greatest amount of emulation between exhibitors, as it directly promotes the well-being of poultry shows. At the same time we cannot speak more strongly than we feel against the fearful amount of "trimming" now unfortunately resorted to by many Game exhibitors, both as to the hackles and many other portions of the plumage of the Game cocks. At Whitehaven Show it is certain that several pens of Game fowls had the under feathers so artistically cut out that they were exhibited almost as devoid of feather as though ready for immediate battle. It is evident this very act caused many fowls to lose all chance of position, although they might have stood well on the prize list if they had been simply left alone. In *Dorkings* the Show was very good, but the fatal objection, now too general, of spurs turning outside the legs instead of inwards, was more universal than we remember to have previously witnessed at any show. The *Spanish* classes were particularly good, more especially the adults, though several of the heavy corrugated-faced birds, formerly far more popular than they are at the present day, were evidently blind altogether, or so nearly so, as to be useless alike for exhibition or procreation. Some excellent *Cochins* were shown, Mr. Fenton sending a collection of great value. Perhaps the best classes of Cochins were the Partridge-coloured, but they enjoyed so slight a proportion of daylight, that it was difficult to distinguish them. In *Brahmas* there was a good display, but one or two of the best pens were labouring under such complete prostration from continuous exhibition, that their chance of success whilst so depressed was obviously bygone. The *Hamburghs* were worthy of most favourable mention, especially the Spangled varieties. As faithful journalists, however, it is our painful duty to briefly allude to the cruelty practised on the cock in Pen 260, of Golden-spangled Hamburghs, that once discovered not only lost a most excellent pen every chance of success, but resulted also in its immediate "disqualification," to say nothing of the absolute disgrace to the owners ever attending such exposures. We really regret that the simple feeling of self-respect, independently altogether of a more proper and a higher motive, does not exercise a sufficient restraint upon the minds of every exhibitor, to prevent the adoption of such grossly unfair means of obtaining prizes undeservedly. It is admitted that such deceptions may possibly at the outset succeed in eluding the Judges, owing to the brevity of time allowed them for making their decisions, and that premiums may, perchance, be secured otherwise unattainable, but on discovery, the disgrace ever following on such exposure, will certainly outweigh unmerited success. Most probably from the cock's comb being either hollow or too wide, the poor bird's comb had actually had a large piece cut completely out of the centre of it, and it was afterwards sewn tightly together again, entirely through and through, the stitches still remaining. Its sufferings must have been great, and Messrs. S. & R. Ashton, of Mottram, have only themselves to blame for their present most unenviable position.

The Black and also the Game *Bantams* were very good; and the *Turkeys* were of unusual weight. One cock Turkey alone weighed 31½ lbs., and a single hen drew the scales in her favour at fully 18 lbs. Some beautiful specimens of Sebastopol *Geese* were also exhibited in capital feather.

Among the *Ducks* shown in the class reserved for "Any other variety" (excepting Aylesburys and Rouens), were two pairs of Shell Ducks, the best of which obtained the high distinction of winning not only their own first prize, but also the silver cup given to the best pen of Ducks of any description. Such an achievement as purely fancy waterfowls being the recipients of a prize of this kind rarely occurs, but in this case so lovely a pen of birds well deserved it. They were exhibited in the most resplendent feather, were faultless in condition, and as being two or more years old were pure in the colour of the bills as the brightest polished red coral. This pen was exhibited by Mr. Charles Jennison, of Belle Vue Zoological Gardens, near Manchester, and reflected the highest possible credit on the management of that gentleman. They were entered at the very low price of £3 7*s.* 6*d.* It is needless for us to say they are no longer the property of Mr. Jennison, there being quite an excitement among many amateurs to claim them. The lucky purchaser, however, we are glad to say, is an amateur of great experience, who has excellent arrangements for their future well-doing, and no doubt under his care we shall be able to report many future successes to this truly magnificent pen.

Among the many other oddities exhibited, was a couple of very nicely plumaged Californian Quails, that although not by any means scarce at the present day, appeared to be quite a novelty in this neighbourhood, the singularity of the reversed crest and general plumage exciting a host of admirers among the visitors all the time the Show was open to the public. This pair of birds was defended by the really prohibitory price fixed on them of £1000! A single hen of this species, still in our possession, laid forty-three eggs last season, and a fellow bird nearly the same number, proving they will, therefore, breed in an aviary freely under favourable circumstances, though the males in spring are usually most pugnacious, and, consequently, many old birds of this description cannot be kept together.

Game.—*Cock.*—First and Cup, J. Fletcher, Stoneclough, Manchester. Second, C. W. Brierley, Middleton, Manchester. Third, J. H. Wilson, St. Bees, Cumberland. Fourth and Fifth, Sir St. G. Gore, Bart., Hopton Hall, Derbyshire. Highly Commended, J Fletcher; Sir St. G Gore, Bart. Commended, J. Haroie, Sorbie Ewes, Langholm. *Cockerel.*—First, W. Boulton. Second and Third, Sir St. G. Gore, Bart.

Game (Black-breasted and other Reds).—First, J. Fletcher. Second, J. H. Wilson. Third, C. W Brierley. Highly Commended, Sir St. G. Gore, Bart. Commended, J. Geldard, Collincroft, Kendal.

Game (Duckwing and other Greys and Blues).—First, J. Fletcher. Second and Third, Sir St. G. Gore, Bart. Commended, R. Pickering, Carlisle.

Game (Any other variety).—First and Cup, J. Fletcher (Piles). Second, Sir St. G. Gore, Bart. (Piles). Third, R. Whittan, Burnley. Highly Commended, H. Thompson, Maiden Hill, near Penrith. *Pullets.*—First, J. H. Wilson. Second, Sir St. G. Gore, Bart. (Duckwing). Third, Rev. W. J. Mellor, Nottingham (Brown Red). Highly Commended, E. Swainson, Nibthwaite, Greenodd, Newton-in-Cartmell (Black Red); Sir St. G. Gore, Bart. (Duckwing).

Dorkings (Silver-Grey).—First, T. L. Jackson, Bush of Ewes, Langholm. Second, H. Heys, Barrhead. Third, R. D. Holt, Orrisehead, Windermere. *Chickens.*—First, R. D. Holt. Second, J. Hardie. Third, W. W. Rattlidge,

Dorkings (Any other variety).—First, H. Beldon, Goitstock, Bingley. Second, R. D. Holt. Third, T. Rogers, St. Helen's, Lancashire. *Pullets.*—First and Cup, T. Rogers. Second, J. Fox, Whitehaven. Third, J. Hardie. Highly Commended, J. H. Wilson; H. Savill, Ollerton, Notts; Messrs. Gunson & Jefferson, Whitehaven. Commended, H. Savill; A. Thompson, Whitehaven. *Chickens.*—First, R. D. Holt. Second, W. W. Ruttlidge. Third, T. Oliver. Highly Commended, Duke of Newcastle.

Spanish.—First and Cup, H. Beldon. Second, Messrs. Burch & Boulter. Third, T. B. Hartley, Heywood, Manchester. Highly Commended, A. Ridpath, Edinburgh; J. Thresh, Bradford. Commended, Miss Biggar, Ecclefechan, Dumfries; E. Brown, Sheffield; J. H. Wilson. *Chickens.*—First, H. Beldon. Second, T. Cliff, Hanley, Staffordshire. Third, Miss Biggar. Highly Commended, A. Ridpath; Miss Biggar; Messrs. Burch and Boulter; D. Gellatly, Meigle. Commended, Mrs. Rawlinson; R. Soaley, Livexy, near Blackburn. *Pullets.*—First, W. Roberts, jun. Second, Messrs. Burch & Boulter. Third, J. Thompson, Bingley. Highly Commended, T. B. Hartley; W. Paterson, Langholm; G. Robinson, Kendal; J. H. Wilson.

COCHIN-CHINA (Cinnamon and Buff).—First and Cup, H. Beldon. Second, C. W. Brierly. Third, J. Cattell, Birmingham. Highly Commended, Rev. F. Taylor, Kirkandrew Rectory, Longtown. *Chickens.*—First and Second, A. Fenton, Crimble Hall, Rochdale. Third, H. Mapplebeck, Birmingham. Highly Commended, W. Copple, Ecclesten, Prescot.

COCBIN-CHINA (Grouse or Partridge .—First, T. Stretch, Omskirk. Second, J. Stephens, Walsall. Third, E. Tudman, Whitchurch, Salop. Highly Commended, C. W. Brierley. *Chickens.*—First, A. Fenton. Second, E. Tudman. Third, J. Herrocks, Tonge, Middleton, Manchester. Highly Commended, C. Benson, Darlington. Commended, J. Horrocks.

COCHIN-CHINA (White).—First and Third, R. Smalley. Second, H. Beldon. Commended, J. H. Wilson.

COCHIN-CHINA (Any colour).—*Pullets.*—First and Third, C. W. Brierly. Second, Messrs. Gunson & Jefferson. Commended, J, Poole, Ulverston.

BRAHMA-POOTRA (Any variety).—First, W. Hargreaves, Newchurch Road, Bacup. Second, Rev. W. J. Meller. Third, H. Lacy. Highly Commended, Mrs. M. Seamons, Hartwell, Aylesbury, Bucks; T. Pomfret, Houghton Lane, near Preston. *Chickens.*—First, R. W. Boyle, Galtrim House, Bray, Co. Wicklow. Second, H. Lacy. Third, J. Pool. Highly Commended, Miss E. A. Aglionby, Hawkshead, Lancashire. Commended, Capt. C. J. Ewen, Lowther Street, York.

HAMBURGHS (Golden-spangled). — First, H. Beldon. Second, J. H. Wilson. Third, F. Robinson. *Chickens.*—First, H. Beldon. Second, C. W. Brierly. Third, N. Marlor, Denton, Manchester. Disqualified, Messrs. S. & R. Ashton, Mottram, Manchester, a piece being designedly cut out of the cock's comb, and afterwards sewn up again.

HAMBURGHS (Silver-spangled).—First and Cup, A. K. Wood, Castle Donnington, Derby. Second, J. Robinson. Third, J. Smalley. Commended, H. Beldon. *Chickens.*—First, H. Beldon. Second, J. Smalley. Third, E. Hird, Ulpha, Broughton-in-Furuess. Highly Commended, J. Robinson.

HAMBURGHS (Golden-pencilled).—First and Third, H. Beldon. Second, S. Smith, Northowram, Halifax. *Chickens.*—First and Third, H. Beldon. Second, T. Wrigley, jun., Tonge, Middleton, Manchester. Highly Commended, R. Burrow, Longtown, Cumberland. Commended, R. Little, Longtown, Carlisle.

HAMBURGHS (Silver-pencilled).—First and Second, H. Beldon. Third, T. Sharples, Forest Bank, near Rawtenstall. *Ccickens.*—First and Third, H. Beldon. Second, H. Pickles, jun., Earby, near Skipton. Highly Commended, T. J. Harrison, Singleton Park, Kendal; J. Platt, Lancashire. Commended, J. White.

HAMBURGH.—*Pullets.*—First, H. Beldon. Second, R. Burrow. Third, J. Birkett, Kendal.

POLANDS (Any variety).—First and Second, H. Beldon. Third, J. Smith, Keighley. Commended, J. Percival, Harborne, near Birmingham.

ANY VARIETY EXCEPT BANTAMS.—First, H. Beldon (Black Hamburghs). Second, Miss A. M. Bass, Broughton, Carlisle (La Flèche). Third, J. Newby, Muncaster Head, Raveoglass (Russian). Highly Commended, J. G. Milner, Leyburn, Yorks (Houdan); W. F. Dickson, Whitehaven (Houdan); F. W. Znrhorst, Dennybrook, Dublin (Houdan).

SELLING CLASS.—First and Third, H. Beldon. Second, J. Thompson (Spanish). Commended, J. Munn, Stackstead, Manchester (Brahmas); G. Arbuthnot, Mairsbank, Edinburgh (Brahmas, Partridge Cochin); C. W. Brierley; J. Towserson, Whitehaven (Dorking); R. Payne, Brierfield, near Burnley; Messrs. Gunson & Jefferson; J. W. Harrison, Spalding (Teal Ducks); M. Irwin, Whitehaven (Polands); E. G. Jones, Parton, Whitehaven (Rouen); G. H. Roberts.

GAME BANTAMS.—First, C. W. Brierley. Second, Sir St. G. Gore, Bart. Third, J. A. Collinson, Halifax. Highly Commended, J. Crossland, jun., Wakefield; A. Fenton; E. Joynson, Liscard, Cheshire; W. Hedgon, Darlington. Commended, Messrs. Bowman & Fearon, Whitehaven.

GAME BANTAMS.—First and Third, J. Crossland, jun. Second, C. W. Brierley. Highly Commended, Rev. W. J. Mellor; J. Shaw, Mount, Pleasant, Halifax; C. Ashworth, Halifax; R. Charlesworth, Halifax. Commended, E. Joynson.

BANTAMS (Gold or Silver-laced).—First, M. Leno, The Pheasantry, Markyate Street, near Dunstable, Beds. Second, T. C. Harrison. Third, Messrs. S & R. Ashton (Silver-laced). Highly Commended, Mrs. Saltmarsh, Chelmsford (Geld-laced).

BANTAMS (Any other variety).—First, Cup, and Second, H. Beldon. Third, H. Savill (Japanese Silkies). Highly Commended, H. Ashton, Prestwich, Manchester (Rose-combed White-booted). Commended, E. Hatton.

DUCKS (White Aylesbury).—First, E. Leech, Rochdale. Second and Third, Mrs. M. Seamons.

DUCKS (Rouen).—First, J. Munn. Second, A. Dickinson. Third, E. Leech. Highly Commended, J. Hardie; J. W. Harrison.

DUCKS (Any other variety).—First and Cup, J. Jennison (Shell Ducks) Second, H. Savill (Carolinas). Third, C. W. Brierley. Highly Commended, E. Hutton (Mandarin; Mrs. J. M. Armstrong, Wigton, Cumberland (Shell Ducks); C. W. Brierley; Sir St. G. Gore, Bart. Commended, Miss Spedding (Ronen and Muscovy)

GEESE (Any variety).—First, Messrs. J. & J. Coupe, Rawtenstall. Second, J. Hardie (Toulonse). Third, H. Savill (Sebastepol). Highly Commended, B. Baxter (Toulouse); J. Hardie (Toulouse).

TURKEYS (Any variety.—First, J. Hardie (Cambridge). Second, J. Fox, Whitehaven. Third, E. Leech. Highly Commended, T. L. Jackson (Norfolk).

RABBITS.—*Lop-eared.*—First, Messrs. Bowman & Fearon. Second and Third, W. Allison, Sheffield. *Any other variety.*—First, J. W. Harrison (Leporides). Second, H. G. Dalton (Angora Buck). Third, J. Lucas (Angora Doe). Commended, D. Fisher, Sandwith; T. Pomfret, Houghton Lane, near Preston (Himalayan Doe).

CONFINED TO THE COUNTY OF CUMBERLAND.

GAME.—*Cock.*—First and Cup, T. Swinburn, Whitehaven. Second, H. Thompson. Third, J. Weeks, Cumberland. Highly Commended, R. Pickering. Commended, J. Harris, Wigton.

GAME (Any variety).—First, J. Brough, Carlisle. Second, G. Bell, Wigton. Third, J. Mitchell, Egrement. Highly Commended, J. H. Wilson. Commended, Messrs. Bowman & Fearon.

GAME (Any variety).—First, J. H. Wilson. Second, R. Pickering. Third, G. Bell, Lamplough.

DORKINGS.—*Cock.*—First, J. H. Wilson. Second and Third, Messrs. Gunson & Jefferson. Fourth, G. Dixon, jun.

DORKINGS (Any variety).—First and Second, Messrs. Gunson & Jefferson. Third, G. Dickson, jun.

SPANISH.—*Cock.*—First and Third, J. H. Wilsen. Second, W. Hale, Whitehaven. Fourth, Withheld.

SPANISH.—First and Second, J. H. Wilson. Third, G. Mawson, Cockermouth.

COCHINS OR BRAHMAS.—*Cock.*—First and Second, Messrs. Gunson and Jefferson. Third and Fourth, W. Burnyeat, jun., Whitehaven.

COCHINS OR BRAHMAS.—First, Messrs. Gunson & Jefferson. Second, Messrs. Bowman & Fearon. Third, J. H. Wilsen. Commended, Messrs. Gunsen & Jefferson.

HAMBURGHS.—*Cock.*—First, J. Hargreaves. Second, J. Fox. Third, J. Brough.

HAMBURGHS (Any variety).—First and Second, Messrs. Bowman and Fearon (Silver-pencilled). Third, J. H. Wilson (Gold-spangled). Commended, H. J. Nicholson, Whitehaven (Geld-spangled).

BANTAMS.—*Cock.*—First, Messrs. Bowman & Fearon. Second, M. W. Taylor, Penrith. Third, J. Mossop, Rottington Hall.

BANTAMS (Any variety).—First, H. J. Nichelsen (Black Red). Second, Messrs. Bowman & Fearon (Black Red). Third, J. Wallas, Highmere, Wigton.

DUCKS (Any variety).—First and Cup, Messrs. Bowman & Fearon (Aylesbury). Second, J. Towerson, Whitehaven. Third, W. F. Dixen. Highly Commended, Messrs. Gunson & Jefferson

A silver cup or piece of plate, given by G. C. Bentick, Esq., for the most sucessful exhibitor of Poultry.—H. Belden.

PIGEONS.

CARRIER.—*Cocks.*—First, J. Thackray, York. Second, E. E. M. Royds, Greenhill, Rochdale. Highly Commended, E. Brown. *Hens.*—First, J. Hawley, Bingley, Yorks. Second, G. H. Roberts, Penwortham, Preston. Highly Commended, E. E. M. Royds.

POWTERS.—*Cocks.*—First, J. Thackray. Second, J. Hawley. Highly Commended, E. E. M. Royds. Commended, J. Thackray; R. Dodge. *Hens.*—First, J. Thackray. Second, J. R Robinson. Highly Commended J. Hawley; E. E. M. Royds. Commended, J. Thackray.

TUMBLERS Almond.—Prize, J. Thackray.

TUMBLERS (Bald-headed).—First, J. Hawley. Second, J. Fielding, jun., Rochdale.

TUMBLERS (Any other variety).—First, J. Thackray (Beards). Second, J. Percival. Commended, J. Thackray (self-colour yellow); H. Mapplebeck.

JACOBINS.—First, F. Else. Second, J. Thompson. Highly Commended, R Thompson.

TRUMPETERS.—First, J. Hawley. Second, R. Dodge. Commended, J. R. Robinson, Sunderland.

BARBS.—First, G. H. Roberts. Second, J. R. Robinson.

TURBITS.—First, R. Thompson. Second, Highly Commended, and Commended, J. Thackray.

OWLS.—First and Second, J. Fielding, jun. Highly Commended, J. Thackray; J. Thompson; E. E. M. Reyds.

FANTAILS.—First, J. Hawley. Second, H. Yardley, Birmingham. Highly Commended, R. Dodge; F. Else, Bayswater, London.

ANY OTHER DISTINCT VARIETY.—First and Second, J. Thackray. Third, J. W. Harrison, Spalding (Hyacinths). Highly Commended, J. R. Jessop (American Passenger); J. Hawley; H Yardley; J. Waitt, Richmond, Sparkbrook, Birmingham; E. E. M. Royds. Commended, J. Thackray; H. B. Whittaker, Middleton (Archangels); H. Yardley.

SELLING CLASS.—First, J. Thackray. Second, J. Waitt. Highly Commended, J. Hawley (Dragons and Magpies); J. Waitt; F. Key, Beverley (Barbs); E. Brown (Carriers); J. Thompson; E. E. M. Royds; H. Miers, Whitehaven (Baldheaded Tumblers).

A Silver Cup or Piece of Plate valne Two Guineas, presented by the Committee to the most successful exhibitor of Pigeons—J. Thackray.

CANARIES.

BELGIAN (Yellow).—Prize, J. Walker.

BELGIAN (Buff).—First, J. Walker. Second, J. Bewley, Penrith.

MULE (Yellow).—First and Second, H Ashton.

MULE (Bun).—First, W. Graham, Carlisle. Second, H. Ashton. Highly Commended, J. Thompson, Marypert. Commended, H. Ashton.

PIEBALDS (Yellow or Buff).—First, J. Boulton, Ulverston. Second, J. Rigg, Cumberland (Buff).

LIZARDS (Gold or Silver-spangled).—First, J. Thompson (Gold). Second, Mrs. F. Johnson, Carlisle (Gold). Highly Commended, J. Thompson (silver).

JUDGES.—*Poultry:* Edward Hewitt, Esq., Eden Cottage, Sparlbrook, Birmingbam; and Richard Teebay, Esq., Fullwood, Preston. *Geese, Turkeys, Ducks, Rabbits, and Pigeons:* W. B. Tegetmeier, Esq., Maswell Hill, London. *Canaries:* A. Benson, Esq., Whitehaven.

SUNDERLAND BANTAM SHOW.

THE Association, known by the appellation of the Sunderland Poultry Society, beld its first Exhibition in the Athenæum on New Year's-day, and it proved a great success, both financially and as a meritorious display of birds. The competition was confined exclusively to Bantams, and considering the small latitude given, the entries were very nnmerous.

Mr. Sim, of Cramlington, officiated as Judge, whose awards appeared to give entire satisfaction. Mr. Sim pronounced the collection to be first-class.

It had been intended at first to have held it as a close show amongst members of the Society only, hnt the unmerous entries indnced the Committee to throw it open to the pnblic. There were several Bantams not for competition, which were very praiseworthy, amongst whicb may be mentioned a pen of White Rose-combed Bantams belonging to Mr. C. Grimshaw, which were well formed and well feathered. The same exhibitor had a good pen of Black-breasted Reds, and may he complimented on the specimen which took the first prize amongst single Pile cocks, which was exceedingly glossy, fnll feathored, and prond in carriage. His first-prize pen of Piles contained a pair of beautiful hens, of remarkable similarity, every mark in one seeming to be identical in the other. The best single cock which took an extra

prize was a Black Red belonging to Mr. F. Grimshaw, the prize being given by Mr. F. Hunter. This specimen was extremely glossy. The first-prize specimen in single Japanese hens was a proud and dignified bird belonging to Mr. G. Lilburn. The same gentleman possessed the most lively and vigerous pen in the Show, which undoubtedly merited the first prize which was awarded to them in the Duckwing class.

The following is the list of prizes :—

Game (Black Red).—First, — Mallen. Second, C. Grimshaw. *Single Cock.*—First, C. Grimshaw. Second, — Rodgers. *Single Hen.*—First, C. Vaux, jun. Second, C. Grimshaw.

Game (Duckwings).—First, — Lilburn. Second, — Mallen. *Single Cock.* —First and Second, G. Lilburn. *Single Hen.*—First and Second, R. Youll.

Game (Piles).—First, C. Grimshaw. *Single Cock* and *Single Hen.*—First, C. Grimshaw.

Game Hens (Black).—First and Second, R. Youll.

Game (Japanese).—*Cock.*—First and Second, G. Lilburn. *Hen.*—First, G. Lilburn.

Extra Prizes.—For best pen in the Show, given by Mr. J. W. Grimshaw. — Mallen. For best Black Red Single Cock, given by Mr. F. Hunter. — Mallen. Ditto Hen, given by Mr. Grimshaw.—C. Young, jun. For best Duckwing Cock, given by Mr. F. Grimshaw. — Lilburn. Best Cock above one year old, given by Mr. Youll. — Hunter, For best single hen of any breed, given by Mr. C. Vaux.—C. Grimshaw.—(*Sunderland Herald.*)

BROOD REMAINING UNDEVELOPED.

INFLUENCE OF AN ABUNDANT SUPPLY OF WATER ON THE PRODUCTION OF BROOD.

The translation from Dzierzon by "A Devonshire Bee-keeper," in page 419, brings to my mind a question which I asked through your Journal some time since, but to which no reply was made. The question was, What is the reason that bees sometimes fail to hatch their young? Doubtless, many may think that cold weather or the want of pollen for food was the cause; but this was certainly not the case with those I referred to, and I will relate one of many similar cases that have come under my notice, and shall be glad of any information on the subject. On the 15th of July I deprived a strong hive of its queen, giving it a ripe royal cell, which was hatched-out and well received in about twelve hours, the queen becoming a mother, or one able to be a mother, in a few days, laying eggs in abundance. I looked forward with anxiety to the time of hatching, being somewhat sanguine of a pure impregnation in consequence of her time out being very brief, the weather not being favourable for a long flight; in fact, so much so, that no other queen ventured out. The period having arrived at which young bees were expected, I made an examination, hoping to see well-marked Ligurians, but to my great disappointment there were only eggs and grubs, in number about twenty thousand. The frames were, therefore, dropped into their places, and I expected that in ten days or so I should be sure to see young bees. When that time arrived I examined the hive again, but not a single young bee or grub was to be seen. Thinking then that the weather was the cause, I commenced feeding, and continued it until the end of October; but all this time not a single bee was hatched. Just as they were ready for sealing they disappeared, although all the rest of my stocks were showing young bees in abundance. It being one of my best hives, I have been much puzzled to account for the aberration, and, as may be expected, it is now greatly reduced in numbers, and as yet not a single bee has been hatched.—A Lanarkshire Bee-keeper.

[I have a very strong impression that this remarkable instance of non-development is due to that mysterious disease foul brood, and that it is in point of fact one of its phases.

As bearing on the fact of the production of brood being promoted by an abundant supply of water, I may relate a mishap which occcurred in the autumn of 1864, when an attempt which I made to transmit a colony of Ligurians to Queensland was entirely frustrated by the extent to which breeding was carried during their imprisonment. The stock was heavy, and being by no means a very populous one, I deemed its store of provision sufficient to last from three to four months. When the voyage, which was protracted to ninety days, was somewhat more than half over, the gentleman who had charge of the bees suspecting something wrong from their unusual silence, lifted and inspected the hive, when the actual state of affairs became at once apparent—their store of provisions had given out and all had died of starvation. That this fatal result was produced by excessive breeding during the voyage, was evidenced by the fact that the mass of dead bees from this originally weak colony lay from 3 to 4 inches deep (or as my correspondent expressed it, the full depth of his finger), in a receptacle 14½ inches square! There was attached to the hive an apparatus for permitting the daily supply of water, which had been carefully attended to. The heat of the tropics had probably stimulated the breeding powers of the queen, and the result had been such a drain upon the stores of the hive as to exhaust them when the journey was little more than half over. —A Devonshire Bee-keeper.]

LIMITING THE PRODUCTION OF DRONES.

In regard to destroying drones and substituting worker for drone combs, either with or without brood, I doubt if so much benefit is derived as is expected, when we take into consideration how prone bees are to transform worker into drone comb when they are inclined to raise drones. The extra honey consumed and the time occupied in doing this will be as disadvantageous as if they had been let alone. Before I possessed Ligurians I used to think that I prevented the raising of drones by giving young queens as early as the season permitted me to destroy the old queens, and substituting ripe queen-cells a day or so afterwards, when, if the weather was fine, not much time was lost in breeding, and if plenty of room was given, a large quantity of worker and very little drone brood was deposited until the stocks were removed to the heather, when, if the weather was fine, they commonly produced a good many drones. I have invariably found that when an unusually large number of drones are being hatched, young queens are brought forward, and a change of queens may be expected.—A Lanarkshire Bee-keeper.

[Never having witnessed an instance in which bees have transformed worker into drone comb, or *vice versâ*, we rather doubt whether they are so prone to effect this transformation as our correspondent imagines.]

OUR LETTER BOX.

Langholm Poultry Show.—The first prize for Spanish was taken by James Thresh, not Huesh. The error is not ours, but the catalogue's.

Feather of White Cochin-Chinas (*A Very Old Subscriber*).—There is so slight a tint upon the tips of some of them, that we should not call them coloured. It is not so strong as in what is called French white.

Breeding Duckwing Game Fowls (*Chanticleer*).—You ask if you are likely to breed good Duckwings from a good Duckwing cock with good pullets of the Black-breasted Red breed? In reply, crossing different colours is wrong, as a rule, and is likely to breed mongrel-coloured mixtures. Breeding from pullets at all is also wrong, as a rule, for they are too young. To breed the best Duckwings, put a good Duckwing cock to from two to four good Duckwing hens. Cock and hens of different strains are to be preferred, with short bodies, square shoulders, good necks and heads, and legs and thighs well placed. As a Cheshire breeder, I should try to obtain the "Old Cheshire Silver Duckwings," once so celebrated, as they are purer and gamer than the Yellow or Birchen Duckwings, and are harder birds in flesh and feather. You may, however, breed some good birds from the cross proposed, as the cock is a Duckwing; most of them will probably have too much red and brown from the Red cross. Willow-legged Black-breasted Reds are softer, weaker, and less game than Willow-legged Duckwings.—Newmarket.

Breeding Dark-blood Pile Game Fowls (*Idem*).—As to whether you are "likely to breed good Dark-blood Piles from Light Pile hens and pullets with a Black-breasted Red cock," Piles are best bred from Piles; hens better than pullets. Bright-red-eyed White-legged Piles are best, of a bright red colour. Dark-coloured Piles are too slow. The Piles, if good white-legged birds, are superior to most Black-breasted Reds. In crossing the colours named for breeding Piles, the cock should be a Pile and the hens Partridge-coloured. However, a few good birds may be thrown from the cross proposed. No Piles are first-rate unless with red eyes and white legs, and reddish birds.—Newmarket.

Size of Game Cocks (*Idem*).—I think all cocks above 5½ lbs. in weight are too slow and often too clumsy. The articled weights for fighting at the Royal Cockpit, Tufton Street, Westminster, London, were from 3 lbs. 6 ozs. to 4½ lbs.; all above this were "byes" or "turn-outs," and fought as such.—Newmarket.

Poultry in Confined Space (*Crève Cœur*).—Buff Cochin-Chinas or Dark Brahma Pootras will best suit you. The food mentioned in the Manual will be correct.

Cross-breeding (*A. R. B.*).—We are not very friendly to crosses, but hardly think that you propose a good one. We do not cross between sitters and non-sitters, which would be the case if the mixture were between Brahma and Houdan. We think very highly of both. The latter are excellent layers; as good, we think, as the former. Both are hardy alike, and as they bear confinement, we see little difficulty in keeping both. Bean and pea meal have a tendency to make flesh hard. They may do for the old stock, but they will not do for those intended for table.

Fattening Turkeys *H. M. B.*).—There is no book published on the management of Turkeys. Shut the birds up in any place where they can perch and roost warmly at night. Let them have a trough of food by them made of oats, barley, and a few beans, all ground together and slaked with milk to be nearly liquid. Let them be fed three times per day, a good bellyful each time, but not more than they will eat. They must have gravel and water. If put up in good condition, three weeks or a month of this should fatten them.

Shifting Hives (*A. B.*).—Any time of the year you may move stock hives a few yards, doing it by little and little, shifting them slightly and with extreme care, to prevent disturbance, every mild day, so as to bring them gradually into their new position.

Stove for Harness-room (*Omega*).—One of Hays's Constant Stoves at 3 0*s.* will suit you. They are advertised in our columns.

WEEKLY CALENDAR.

Day of Month	Day of Week.	JANUARY 24—30, 1867.	Average Temperature near London.			Rain in last 39 years.	Sun Rises.	Sun Sets.	Moon Rises.	Moon Sets.	Moon's Age.	Clock before Sun.	Day of Year.

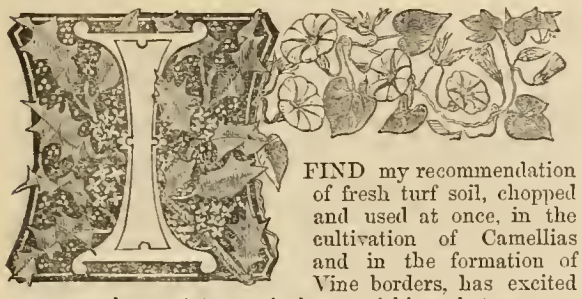
30	W	Begonia manicata.	44.3	32.0	38.2	20	45 7	43 4	21 3	after.	24	13 32	30

From observations taken near London during the last forty years, the average day temperature of the week is 43.3°; and its night temperature 30.3°. The greatest heat was 57°, on the 29th, 1863; and the lowest cold 15°, on the 25th and 27th, 1855. The greatest fall of rain was 0.90 inch. N.B.—The Calendar contains the names of plants flowering in the greenhouse.

TURF SOIL.



FIND my recommendation of fresh turf soil, chopped and used at once, in the cultivation of Camellias and in the formation of Vine borders, has excited some surprise; yet to me it is astonishing that any one can doubt the superiority of fresh turf over that which has been kept a year or more.

Why is turf soil valuable? If only because it is fresh to the plant we wish to grow, any soil which has not grown a Vine or Camellia ought to be as good. If it owes its value entirely to the vegetable matter it contains, a mixture of leaf mould with any good garden soil ought to be as valuable. I contend that turf soil is not only fresh—that is, unexhausted of the food required by the plant we wish to cultivate, but that its value greatly depends on the mechanical division of the soil by the fibrous vegetable matter it contains.

If this view be correct, why should turf be kept till the fibre is almost decayed before it is used? The time the soil will remain open and elastic must be reduced. If turf an inch thick be cut from a rich pasture of light loamy soil can it require sweetening, as it is called, before it is fit for use?

What idea does this term sweetening convey? I suppose the exposing any unoxidised matters to the action of the oxygen of the air. Is this very well carried out by stacking the turf in large heaps, as is generally done? Nay, can such unoxidised matters be found in turf soil? I have reason to think that in a rich pasture every particle of soil for several inches in depth has been swallowed by earthworms, and cast in its turn on the surface of the field. If this were not the case it would, I think, be impossible to account for the following facts.

Turfcutters often find at various depths layers of lime, ashes, &c., with which the field has been manured years before. These substances have disappeared from the surface, and are found in horizontal layers deep in proportion to the time which has elapsed since they were spread upon the surface. However many stones may be found in the subsoil of an old and rich pasture, few will be found near the surface; they have sunk, and are always sinking, whilst worms bring particles of soil from below them to be cast on the surface. What more perfect exposure to the action of oxygen could be secured than is insured by this process?

It may be objected that some grass fields have plenty of stones near or on the surface. Yes, because they are too poor to breed earthworms in any quantity. Soil or turf from such fields will be of little value.

Some years since I wrote an account in "our Journal" of a successful experiment which suggested itself to Mr. Jefferson, a clever Yorkshireman, head gardener to — Garside, Esq., of Worksop. Litter just as it came from the stable (a mixture of straw and fresh horse-manure), was passed through a chopper and cut into chaff. This chaff mixed with good garden soil grew Pines, young Vines in pots, and many other things, of which any man might be proud. Mechanical division of the soil was here secured by the fresh undecomposed straw.

In conclusion, I may say that I do not believe any mixture of soils will grow Camellias as strongly or as healthily as turf from a light sandy loam cut thin, chopped, or, which is far better, pulled to pieces, and used at once.—J. R. Pearson, *Chilwell*.

WALK-EDGINGS FOR VILLA GARDENS.

I was lately asked by a gentleman, the proprietor of a rather well-kept villa garden, what he ought to do with his Box-edgings, as twice within half-a-dozen years he had nearly renewed them throughout their length, and they were again in a very forward state for a repetition of that process. On going to see them I found they were indeed anything but lines of beauty; yellow and sickly, made up of two or three different varieties of Box, none of which seemed to be enjoying themselves very much, full of blanks, they were for the most part edgings only in imagination, and before long I fear they will not be even that. When asked what sort of soil was most suitable for Box, with some confusion I had to confess I did not know.

This villa garden is a rather light loam, with a gravelly bottom, and grows most plants beautifully. Roses flourish there with only a very indifferent supply of manure, but Box it will not grow; yet on some soils, which to my unchemical eye seemed exact counterparts of this, I have seen it so luxuriant that it was almost impossible for man and shears to keep it down. Not being able to doctor the old, I advised the gentleman to adopt a new edging altogether; and though Box is undoubtedly by far the best live edging we have, yet there are many substitutes not altogether unworthy our consideration.

First in the list, although, perhaps, not first in order of merit, stands the common Furze (Ulex europæus). Possessing as it does in no mean degree so many of the good qualities of Box, I am surprised it is not oftener used; it dresses well, the seed is cheap, and hardly any place seems too poor or dry for it. By sowing the seed where the edging is wanted, and when up by using the shears a little more frequently than we do with Box, it may be made to assume a really neat and respectable appearance. Of course it cannot well be kept below the fashionable height of 3 inches, but I have seen it dense and close at 5 or 6.

The small-leaved Periwinkle (Vinca minor), does very well if kept from straggling by pegging and clipping, and the fine fresh green of its foliage is a great recommendation. It succeeds under shade and drip better than any shrubby edging we have.

The Herbaceous Heath (Erica herbacea). This, with

some of its relatives, is often used, though it has not much to recommend it, being difficult to keep in order, and plants here and there often die out, making unsightly blanks in what ought to be, whatever it be composed of, one unbroken line.

Of the host of herbaceous plants used, comparatively few are well adapted for the purpose. Most of them make a broader line than good taste can sanction or economy allow where narrow walks and narrower borders are the rule, as they too often are in the case of villa gardens, added to which many of them require relaying every year, and most of them every two years, to keep them at all within the bounds of respectability.

One of the least objectionable in the above respect is that pretty little plant the Gentianella (Gentiana acaulis). It is most at home in wet damp places, where it will go on year after year throwing up its great Gloxinia-like tubes without being lifted or receiving any attention beyond a slight docking with the spade and line every spring when done flowering.

Several of the Sedums answer very well, but the flowers require to be clipped off before the seeds ripen, as they spoil the gravel with seedlings.

The Sea Pink (Armeria maritima), is so well known and so often used for hack edgings that I need only say it has many good qualities to recommend it, not the least of which is the facility with which any quantity of it can be procured, if within a reasonable distance of the sea.

The Auricula is also a great favourite in small gardens; so is the Arabis family, especially the variegated variety, but of it a reserve ought always to be kept to make up blanks, which will frequently occur.

Many of the Saxifrages make neat edgings, but require frequent re-arrangement.

There are many others that are largely used, of which not very much can be said in their favour. All the Daisies are highly objectionable on account of the trouble they give. The equally numerous family of Primulas are too large-leaved, and Mr. Wills's long-lost *protégé*, Viola cornuta, though I hear some are using it, is of far too genteel a nature to enter the lists against tacketty boot-toes and accidental barrow-wheels.

Perhaps on the whole the best substitute for Box will be found in dead materials. Of these, white dressed freestone takes the highest rank, and indeed in situations where weight and massiveness, or harmony with architectural surroundings, are desirable features this is indispensable. Unfortunately its costliness places it almost beyond the pale of common use; but a wooden kerb well painted with thickish paint, then neatly sanded, and, when dry, again coated with thin stone-coloured paint, if well done, looks remarkably like stone, and endures a long time.

Cast-iron edgings as usually made are also rather too expensive ever to become very popular, but as they will last any length of time, this expense is more apparent than real. As it is, a very neat and by no means insignificant-looking edging could be made for about 1*s.* per yard according to weight.

With regard to terra cotta edgings I have not had the advantage of seeing many that have been laid down for any considerable period; what I have seen struck me as being what we would call little more than half-hardy, a great many little corners and edges being scaled off by the frost, particularly about the joints. They look well, however, and as my opinion of their endurance must be taken in connection with a Scotch winter, they may, perhaps, do very well in England.

I was once acquainted with an old, retired, sea captain, who, after carrying Her Majesty's mails for many years to somewhere round the Cape, settled down in a snug little villa not far from the seaside, as most old sailors do, and took to gardening. His tastes certainly might not be of the purest, nor his theories, of which he had a great many, the most correct; but his shell walks were the whitest and his edgings the neatest in all that locality, and they were neither more nor less than old ship cables of about 2 inches in diameter. The way they were put down was this:—The ground being marked off, short stout stakes were driven in to a little below the level of the walk; along the tops of these common paling rails were nailed to serve as a bed for the cable, to which it was fixed by stout nails, and when the gravel was raked in the woodwork was entirely hidden. Than this, for a simple, not very expensive edging, nothing could be more artistic.

All up and down our shores, but more particularly on the south and west coasts of England, there are to be met with whole acres of rocks and boulders all bored over with little holes as if millions of fairy wimbles had been busy at work ever since the creation. This is the handiwork of several species of burrowing molluscs, known to those skilled in marine lore as Pholades, Saxicavæ, &c., and the means they use in making and the ends for which they make these countless holes in the hardest rocks have long been a puzzle among scientific men. Be that as it may, these molluscs manufacture one of the best materials for making rustic edgings that I know of. Broken up into pieces of nearly uniform size, and either laid on the ground or fixed on a foundation of brick by means of cement, it has a more unique and coralline appearance than anything else of the kind obtainable in this country. It is most suitable for walks in or about rockeries, ferneries, &c. Even for making rockeries themselves, if such caricatures there must be, it is much better than ordinary cobbles, tree roots, bottlework, clinkers, and all the other conventional abominations which when tumbled together are dignified by that name.—Ayrshire Gardener.

GARSTON VINEYARD.

(*Continued from Vol. XI., page* 404.)

I have the more pleasure in resuming my description of the Garston Vineyard, because it will enable me to prove to "Vitis" and other readers that I only stated the truth in my article on making Vine borders. What "Vitis" says may be correct in reference to the ridge running through Hertfordshire, Essex, and Cambridgeshire, and which is composed of a calcareous sandy loam, a soil in which the Vine luxuriates without borders or anything except water. Give the Vine plenty of water in the above localities, and a moderate amount of horticultural skill is all that is necessary to grow good Grapes; but confine the roots of the Vine within the walls of vineries in borders only 3 feet deep, follow the practice which has pleased "Vitis" so much—namely, watering only once a-month, and I think "Vitis," or any one else would look in vain for good results. In Lancashire both climate and soil are adverse to the Grape-grower, and "Vitis" will therefore perceive that it is wrong to dogmatise on any subject, no matter what, when conditions differ.

Some years ago, long before Mr. Miller was heard of as a Grape-grower, there was a Mr. Nash at Bishop Stortford, who surprised everybody with his fine Grapes; but there was no merit due to Mr. Nash or his gardener—the soil was there ready, and they could not help growing good Grapes. The one want above all others to be attended to in the sandy soil of Bishop Stortford is water. The Vines will require it weekly, or oftener, during their season of growth. The great merit is in producing results under unfavourable conditions. This Mr. Meredith has done. He has not only had to contend with climate, but with the constant outlay which his undertakings involved.

Nine years ago last March Mr. Meredith began carting bricks to what was then a green field. One of his first proceedings was to build a good substantial dwelling-house, which is very commodious and pleasantly situated; most of the rooms upstairs and down are nicely heated with hot water. During the first year Mr. Meredith built his dwelling-house, four vineries, and four Pine-stoves, besides several other smaller houses and pits for plants. From three of these houses he has cut his most extraordinary Grapes. These results will at once show that when he made the borders nearly ten years ago, he clearly saw that to make a shallow border for permanent Vines on a cold lazy subsoil was useless. He was also well aware that to insure success it was necessary that a border should be made both outside and in. He had likewise a settled conviction that it was necessary, though expensive, to make a good lasting Vine border; if he had not done so he would have been under the necessity of replacing the splendid Vines that have borne such enormous crops of good Grapes, and which still give promise of greater results in future years, with others which, as soon as they were arriving at the proper age and strength for bearing good crops, it would have been necessary either to have lifted whilst another border was being made for them, or to have replaced with fresh Vines. In either case there must have been a break of a year at least before any favourable results could have been obtained.

The front of Mr. Meredith's dwelling-house faces due south. On each side of the house there is a lean-to vinery, 55 feet by 17. The healthy Vines, and the magnificent Grapes which these houses produce every year, abundantly prove that aspect has nothing to do with the well-being of the Vine. One of

these houses, No. 1, which I shall first describe, is on the west side of Mr. Meredith's dwelling. Not a gleam of sunshine ever falls on this house earlier than 2 P.M.; and as the house is principally devoted to late Black Hamburgh, Alicante, and West's St. Peter's Grapes, these being kept back as much as possible till late in the spring, we may safely assume that very little sun ever shines on the house during the most critical period of the crop, which I consider to be from the time the berries commence stoning till they change colour. The Vines in this house, as in most of the others, are planted inside, and about 2 feet apart. The front rests on pillars. The border is raised to within about 2 feet of the glass in front. There are no front lights, but there are some ventilators 2 feet by 10 inches along the front wall; and the border, both outside and inside, is built up above these, leaving merely a square hole outside, the size of the ventilator. Through these openings the air is admitted to the house. The border outside is about 12 feet wide, that on the inside about 5 feet, and it is intended to add another piece.

I cannot too forcibly remind those who contemplate making Vine borders that one of the most important precautions to insure success is making the border by degrees. I would make a section of the border complete, and plant the Vines in their proper position the first year, then add a yard or so to the border outside, and thus proceed every year till the full width had been attained. By these means the roots would take firm hold of the border as the Vines grew in strength; and at the end of three years the roots would occupy every inch of the border, and would have thoroughly established themselves, and be in a condition to produce splendid crops of fruit. At the time of my visit (October), the Vines in this house were clothed with abundance of fruit and foliage, not a yellow leaf was to be seen; and the Grapes, though not ripe, were as black as Sloes. Here were to be seen splendid bunches of Black Hamburgh, Black Alicante, and West's St. Peter's.

On this side of the dwelling-house is situated the dining-room, and from it a glass door opens into the vinery. The effect when sitting in the room is very pleasing. The green and healthy foliage, and the clusters of jet black Grapes, are seen to great advantage by the subdued light. The Vines were planted in August, 1857, and were then young plants in a growing state.

After leaving this house we pass round the north side of the dwelling. Here are two small lean-to's filled with greenhouse plants; the small squares of thin glass which cover the roofs and ends remind one of the time when horticulture in general and Grape-growing in particular were in their infancy. Passing through these houses we arrive at the east side of the dwelling, where we enter No. 2, or what Mr. Meredith calls the east house. It is of the same dimensions as the west house, and is filled with Black Hamburgh Vines, from which have been cut the marvellous bunches that have astonished every one at the metropolitan and other shows for the last four or five years. The Vines were planted in June, 1857. The house is built and the borders made just in the same way as in the case of No. 1.

From this house was cut the bunch of Black Hamburgh weighing 6 lb. 5½ ozs., exhibited by Mr. Meredith at the Edinburgh International Fruit and Flower Show last September twelvemonth. Will "Vitis" ever cut a bunch like this from any Vine grown in his shallow inside border? At the last Edinburgh Show another bunch, cut from the same house, and weighing 6 lbs., was exhibited. There are twenty-six Vines in the house; the number of bunches borne by each every year will average eight, and their mean weight will be about 3½ lbs. The Vines from which the large bunches were cut had four and five bunches on at the same time. The length of the canes in this house is about 12 feet. This shows the fallacy of the report that has been spread abroad by persons who have not seen the Garston Vineyard—that Mr. Meredith only grows one bunch on a Vine for exhibition purposes. He told me he once tried the one-bunch system, but that it proved a complete failure; and the particulars about it are, as nearly as I can recollect, as follow: Noticing on one or two occasions some extraordinary shows on some of his strongest Vines, he was induced to leave only the one bunch, thinking he would cause the Vine to throw its whole energy into that bunch, and by these means he fancied the berries would be swelled out to an enormous size. The laterals were duly pinched out, and the Vine treated just like the others growing in the same house. The result was that the bunch shanked and the berries refused to colour, whilst all the other Vines in the house produced a large and well-finished crop of fruit; and such single bunches were the only ones that shanked, or that did not colour. The result was nothing more than one might expect, if we take into consideration the strength of a Vine in the most luxuriant health, with all its energies concentrated on one bunch. Had there been four or five more bunches left on the Vine, or only two besides the selected bunch, it is probable it might have realised Mr. Meredith's expectations; as it was, the strength of the Vine was absorbed by the foliage instead of by the single bunch.

The sun leaves the house to which I am referring about 1 P.M., and when we take into consideration the wet and sunless season of 1866, it seems almost impossible that such splendid results in Grape-growing could have been obtained from houses whose aspect in both cases, one would think, is so at variance with the law laid down by gardeners up to a very late period—namely, that the aspect for a vinery must be due south. These houses and another facing the north, which I shall describe in the course of my ramble through the Garston Vineyard, will abundantly prove that any aspect will suit the Vine, and that a large amount of light is not absolutely necessary to give Grapes a good colour and fine finish.

Here, then, is comfort for the amateur and those whose sites for vineries offering a southern aspect are few in number and very much limited as regards extent; for they may have their vineries in any back yard, provided it is not too much hemmed in with other buildings and not shaded by trees, if they will make their borders according to the instructions I have given, and treat their Vines liberally; but on no account must they follow up the once-a-month system of watering, recommended with such confidence by "Vitis."

I was astonished to see no covering of any sort on the outside borders. I was more astonished when Mr. Meredith told me there had been no covering of any kind on the borders throughout the summer, and that the Vines had absorbed their share of the enormous quantity of rain that had fallen in 1866. What shall we say after this, about confining our Vines to inside borders, and subjecting them to the severe ordeal recommended by "Vitis?"

And now a word about the expensive style of Vine-border-making that "Vitis" so sternly condemns. Supposing the material and labour for making the border of the vinery above described to have cost Mr. Meredith £50 ten years ago, let us see what the produce of the house has been for the last six years. I have stated that there are twenty-six Vines in the house, that the average quantity of bunches produced by each Vine was eight, and that the mean weight of the bunches was 3½ lbs. I think that the average price per pound for the quality of Grapes would be 5*s.* at the season they are ripe, which is from July to September: we find, then, that the twenty-six Vines would produce in six years 4,368 lbs. weight of Grapes, and that the commercial value at 5*s.* per lb. would be £1,092. I have no authority from Mr. Meredith for quoting the above figures, I only do so to show that it is worth while, even in a commercial point of view, to make a Vine border thoroughly, and that it is better to allow Vines to properly establish themselves before fruiting. "H. S.," near Staines, would do well to take a hint from this, and not be in a hurry for the half ton of Grapes, but wait a reasonable time before he expects such a large return for the small outlay. The Vines in the house I have just been describing are in perfect health and vigour, and there is no doubt if Mr. Meredith is spared to superintend their management, that they will present the same appearance in twenty years' time. Of course every year they will want a larger amount of food in the shape of liquid manure, with annual surface-dressings of bones. The Vines are pruned back to the last eye at the base of the shoot every year. It would do a Vine-grower's heart good to see the condition the Vines are in, and if he minutely inspected them he would see large numbers of dormant eyes starting near the base of each shoot.

In describing what I saw at Mr. Meredith's vineyard, I cannot help making comments as I proceed. If, however, I may be thought wrong in any of the ideas I may have formed, I am at all times open to correction, and shall always feel grateful for any information that any of the correspondents of The Journal of Horticulture may be disposed to give in an open and friendly manner

The houses numbered 3, 4, 5, and 6 are all span-roofed, and are in a line with the house last described. They are used in the early part of the summer and spring for growing on young Vines. They are now filled with a fine, healthy stock of Indian

Azaleas and a miscellaneous collection of greenhouse plants, for Mr. Meredith having two very intelligent sons, who have just finished their education, it is his intention to commence a general nursery business, which will make his establishment more interesting to visitors. There are two fine pieces of ground right and left of his dwelling-house, and facing the road, on which he intends to build some magnificent houses for plants.—J. Wills.

(To be continued.)

COLLECTING AND STORING ICE.

I mentioned (page 30), my intention to throw water over a pond that had half an inch of ice upon it, too weak to stand the ice-hook, and which I feared would not become much thicker even by sharp frost, as there was a depth of fully 3 inches of loose snow on the ice. The plan answered so well that I would not hesitate to resort to it again whenever there was danger of the frost not continuing. The water was thrown with jets, so as partly to melt and partly to go underneath the snow on more than one-half of the pond, as we could not make it reach towards the centre. On the next morning on all the part so watered we had a fine plane of thick ice, but of two distinct properties as respects density, the ice formed first, before the snow, being much harder than that formed above it from the melted snow, though when welded together the freezing went right downwards as usual. All the part so watered came out in large pieces; but when, towards evening, we came to the unwatered part we could make but little of it, the partly congealed snow on the top slipping off the ice, as we were obliged to draw it towards us.

It is not always that such a chance can be obtained; but the blocks of ice, although causing extra work, even when moderately broken, to place in the ice-house, packed more firmly there than could have been done if the ice had all been of uniform hardness, unless well broken.

When the space to be filled is small, much will depend on firmly pounding the ice after breaking it well; but when the capacity of the ice-house is large, and the weather uncertain, I would prefer a large quantity of ice imperfectly broken to a smaller portion however well pounded. I have often proved that fifty loads housed somewhat roughly will keep longer than forty loads well pounded. In fact, provided there is enough small and pounded ice in which to pack the larger pieces, the ice will keep nearly as well as if all were pounded small. The great point is to prevent air circulating through the mass, and a large heap will soon become compact even from its own weight. I may here mention that for many years I have used neither salt nor straw about or over the ice, merely packing the doorway with straw.

In general our old-fashioned ice-house does not need air-giving, except when it is opened for use; but there are a few occasions when, if the surface were covered with dry straw, it would be the better of a small air-pipe from the roof. The low state of the barometer outside, and especially before, during, and immediately after a thunderstorm, seems to have an effect on the atmosphere of a close, shut-in ice-house, very much similar to that which it is said to have on the atmosphere of a deep coal pit. I have frequently noticed that in a fine day in summer, with the barometer approaching 30 inches, the air of the ice-house would feel comfortable and dry, and the surface of the ice be comparatively dry; whilst in an equally fine, sunny day, but with the barometer falling to 29 inches, and with signs of an approaching electrical disturbance, the opening of the ice-well would often be attended with an outpour of visible vapour. Now, it would be better in every way if this vapour escaped as formed, instead of surrounding and hanging over the ice; and such are the cases in which I think it would be better that the ice should be covered with a dry, non-conducting material, as straw, and that there should be an air-vent by a small pipe.

I have during the season had several communications as to the success and the non-success of ice-heaps from dairy farmers and others, with whom ice is becoming every season more a matter of importance. I think that when the heap has proved more or less of a failure, this result has been chiefly caused by the smallness of the heap and the insufficiency of the covering. In this respect it should not be forgotten that, other things being equal, the keeping of the ice will not depend on an arithmetical progression as to the size of the heap. Thus, a heap of a dozen loads will not keep half the time that a heap of twenty-four loads will do; nor yet will a heap of twenty-five loads keep half the time that a heap of fifty loads would do. In fact, for all practical purposes, it is scarcely worth while making a heap if it will not contain forty or fifty cartloads—that is, before the ice is broken. The larger the heap the more compact it is—that is, the fewer superficial feet exposed the better proportionally will the ice keep; and these advantages are, perhaps, best secured by a round blunt cone, though a long blunt ridge, like a flat span-roof, answers very well. In neither case should the base be less than from 12 to 16 feet, and the height should not be less, if possible, than 7 or 8 feet. I have known cases of a dozen loads of ice being so emptied down rather roughly, and some cartloads of straw piled over the heap, and yet the ice came out serviceable in July; but there would be a better chance if more ice had thus been collected and the work had been done more systematically, though it is sometimes wonderful how long ice will keep when heaped in this rough way.

Some inquirers are puzzled because they cannot find such favourable places for forming a heap as I and others have described. In this there need be no difficulty. If the ground is quite level a small trench will have to be made, a yard or 4 feet from the heap, and that, too, will have to be covered with straw to prevent the heat acting on the trench. It is rare, however, that a little mound, 6 or more inches higher than the general ground round it, cannot be found; and in such a place there will be no necessity for a trench or anything of the kind, as, if the ice be placed on a few inches of brushwood, any little melting that takes place will find its way to the lower ground imperceptibly. No better chance for forming such heaps could be found, where water is near, than a frosty time when the ground is covered with snow, especially if the heap is to be formed in the corner of a meadow, as not only could large blocks be built in the sides of the heap, but a considerable portion of the surrounding snow could be brought up with the ice; and a good watering over all, and the ice exposed to the severe frost, would make the whole heap like a solid block of ice.

No class of men could form these heaps more economically than farmers, as the straw covering would cost them little or nothing, for it would always come in for use when it had served its purpose over the ice-heap. The straw must be dry when used, and ultimately, when rough-thatched to throw off all wet, it should not be less than 3 feet thick, though I have seen good heaps with not much more than 2 feet of covering. A hole will have to be carefully taken out when ice is wanted, and it would be well to have small bundles of straw to fill in the hole, and an old door over all outside. The straw covering should extend a few feet on the ground round the heap, the farther the better, to prevent the ground becoming heated near the heap, for though earth is a slow conductor of heat, it does conduct, and the farther the straw extends the greater will be the safety of the heap in this respect. From want of this consideration I have known heaps that melted prematurely, not from the heat finding its way through the thatching or covering, but from rising through the ground beneath.

Two more observations will make all clear. Unless you make something like a regular house above ground, be satisfied with covering the ice and laying the straw close on it without any intervening frame, so that as the ice shrinks the cover will sink with it and leave no space for air. Make sure that the covering will not produce heat by decomposition; it must, therefore, be dry. Lastly, avoid everything like holes in the covering, whether by birds, rabbits, or rats, as all these holes will merely be ventilators to let the warm air in. A series of tar strings round the heap will help; a fence of fine wire netting would answer admirably.

My apology for these remarks is the hope that ice-heaps will be more general, not only in dairy farms, but that they will also be considered essential adjuncts to all hospitals and infirmaries, where ice from other sources cannot be easily or quickly obtained.—R. Fish.

PASSIFLORA LAURIFOLIA SELF-FERTILISING.

In the last volume, page 348, your correspondent "A. B." writes on the cultivation of Passiflora laurifolia, or Water Lemon. I perfectly coincide in his remarks on the cultivation, but he is in error about its impregnation, as I know by long experience that it is fertilised by the pollen of its own flowers. I have grown upwards of two hundred fruits annually on one plant, all of which were fertilised by its own pollen. I consider

it advisable to name this, as some might be deterred from cultivating Passiflora laurifolia if they were obliged to grow other kinds for the pollen.— J. Jones, *Gardener, Boothby House, near Lincoln.*

THE INTENSE COLD AND ITS CONSEQUENCES.

Nenagh, Ireland.—On the night of the 2nd, the thermometer registered 1° below zero, and on the 3rd it again fell to zero. Such a degree of cold has never, I believe, been heard of in Ireland, even within the memory of our venerable friend, "the oldest inhabitant." My thermometer was pronounced incorrect, as "that was a degree of Canadian cold never experienced in England or Ireland." This I was slow to believe, as the instrument was procured from a well-known maker. The fact was, that I put it on a stand about 1 foot from the ground, out on the grass away from all shelter, thereby testing the real temperature more accurately than some of my disbelieving friends, whose thermometers were hung on a wall outside their windows. From what I have read in "the Journal," and daily papers since then, I think I may feel certain that my thermometer is correct. As to the effects on vegetation in my own garden, as far as they are yet apparent, almost all the vegetables, including a fine crop of early Broccoli, Savoy and other Cabbages, in different stages, are either destroyed or severely injured; and the damage done in frames which were thought to have been securely protected, is too melancholy to record.—C.

Barrow-on-Humber, Lincolnshire.—The temperature as taken here by a Negretti & Zambra's thermometer, suspended in an exposed quarter of the kitchen garden, the aspect, north, was as follows:—

	Lowest Temperature.		Lowest Temperature.
January 1st.....	20°	January 5th	12°
„ 2nd	12°	„ 12th	20°
„ 3rd	22°	„ 15th	20°
„ 4th	16°		

Evergreens do not seem to have suffered here at present (13th). It has not been so cold here by 12° as it was on Christmas morning six years ago. The thermometer then fell to 32° below freezing. Aucuba, common Laurel, Portugal Laurel, Bays, Cedrus deodara, and Araucaria imbricata were then killed down to the snow-line.—The Gardener, *Grove House.*

Wickham Market, Suffolk.—On the 14th, the thermometer was down to 9°, being 23° below freezing.

Cambridge.—At Gonville Nurseries the lowest temperatures occurred on the 2nd and 4th, when the thermometer fell to 8°. —J. J. Chater.

Winchester.—Near the Cathedral, on the 4th, the thermometer fell to 4°.—J. Newberry.

Oakham, Rutland.—The lowest temperature registered here, occurred on the night of the 4th, when it was 9°.—G. B., *Barley Thorpe Gardens.*

Hanworth, Norfolk.—During the night of the 4th inst., the thermometer, on a north wall, 4 feet from the ground, fell to 10°.—E. Sendall, *Barningham.*

Laverstoke House, Hants.—One of Negretti & Zambra's registering thermometers hanging in an open situation on a wall in the garden, about 2 feet 6 inches from the ground, indicated on the morning of the 4th inst., 31° of frost, or 1° above zero; and on the 5th, 26° of frost, or 6° above zero. Much damage seems to be done to the shrubs. Laurels are very much scorched. Of Laurustinus the tops have been killed down to the snow-line; Arbutus and Garrya the same. Of the hitherto-considered hardy Brussels Sprouts and Sprouting Broccoli, about one-third has been very much injured, if not killed. The other sorts of Broccoli appear all right, owing, no doubt, to their being laid close to the ground, consequently they were better covered with snow. I was very much surprised at your registered temperatures being so much lower than ours, as usually we do not vary more than 2°. We are on a cold part of the Hampshire Downs.—John Alliston, *The Gardens.*

Liverpool.—The lowest temperature on the night of the 4th was 12°, or 20° below freezing point, with a dense fog. The thermometer was self-registering, 3 feet from the ground, and in an open situation. The height here above the sea level is 147 feet.—W. Biggs, *Sandfield Park.*

Brigg, Lincolnshire.—On Wednesday morning, the 2nd, my thermometers (Negretti & Zambra's), registered 3.5°, and on Saturday 7°—that is, of course, above zero. Several standard and dwarf Roses appear killed, as in 1860—namely, such kinds as Lord Clyde, King's Acre, Madame Vidot, Pierre Notting, and several others.—J. B., *Bracken Hill.*

Yorkshire.—"A correspondent informs us that the frost has killed two thousand of his standard Rose trees. One of Negretti and Zambra's thermometers registered on two evenings 5° below zero. The same amount of frost killed 1500 Rose trees in 1860. He says his Roses budded on the Manetti stock are safe, and alive for about 4 inches above the soil, the cover of snow having saved them. These will shoot up vigorously from below in the spring. He adds:—'No doubt you will hear of many other rosarians having their hopes blighted for the ensuing summer.'"—*Yorkshire Post.*

Armagh, Ireland.—During the past week we have been visited by one of the most severe frosts that have occurred in this locality for half a century, making sad havoc among vegetables and shrubs. The thermometer, one of Casella's registering, on the nights of the 2nd and 3rd was 1° below zero. Broccoli, Brussels Sprouts, Scotch Kale, and, in fact, everything that was not covered with snow, were totally destroyed. Roses, Laurustinus, and Bays were quite killed. Rhododendrons, Evergreen Oaks, common and Portugal Laurels were very much blackened, and there are numbers of other shrubs which I fear will never recover.—E. Welch, *Palace Gardens.*

Haddington, East Lothian.—As suggested by you at the close of the year, I had intended to note down and send to you the names and times of flowering of plants in my garden during this month. I noted that on the 29th December the Winter Aconite was in bloom and Snowdrops peeping through the ground; but on the 31st it began to snow, and on the 1st inst. an intense frost set in, and since then we have had four or five distinct falls of snow, with severe frost intervening. On the 1st the thermometer in my garden at 11 P.M. stood at 5°, on the 3rd at 9°. There was a short interval of thaw on the 8th, but since then snow and frost have succeeded each other. I have not been able to inspect my garden minutely, but I anticipate there will be more plants killed or injured by frost than in any season since 1860-61. I am afraid the Tea-scented Roses will be cut to the ground. Lonicera aureo-reticulata seems quite lifeless. It will be impossible to ascertain the extent of injury to fruit trees till spring has set in, but I am much afraid that the buds of my Almond trees have been destroyed, and am even doubtful of the Apricots. A fine quarter of Broccoli, which was producing beautiful heads daily before the storm, seems reduced to pulp. I look forward to see traces of great destruction when the storm abates.—John Ferme.

Hay, Herefordshire.—My thermometer (Negretti & Zambra's), which marked 7° on the night of January 3rd, the next night marked 3° higher—namely, 10°, and last Monday night (14th), it fell to 3½° above zero.—F. F., *Brook House.*

North Wales, Corwen.—We are much exposed to the north and north-east, lying low on a gravelly subsoil. The thermometer, hung against the house and facing S.E., registered 3° above zero on the 4th inst. Arbor Vitæ looks much cut up, but Portugal Laurels and Holly are not in the least damaged. Roses look much cut up. They are trained to a wooden fence facing south-east, and have some thick branches of Spruce Fir stuck in the ground in front of them, which I find answers better than anything I have tried. Duc de Rohan, much injured; Comtesse de Chabrillant, dead, I fear; Celine Forestier, nearly dead; Mrs. Bosanquet, nearly dead; Duchess of Norfolk, dead. Baronne de Heckeren, Lord Clyde, Madame Boutin, and Celine Forestier, as standards in the open ground, nearly dead. Roses doing well on a S.E. trellis—Gloire de Dijon, Admiral Nelson, Souvenir de la Reine d'Angleterre, Madame Domage, Souvenir de Leveson Gower, Monsieur de Montigny, John Hopper, La Reine, Mrs. Standish, Général Jacqueminot, General Washington, Madame Vidot. I have many more Rose trees, but could not take account of them, they being covered with snow.—T. Elcome, *Rhug Gardens.*

Bedale, Yorkshire.—The lowest temperature registered here was 5° below zero, or 37° of frost. On the evening of the 1st of January the ground was covered with 6 inches deep of snow, and with continual additions it has since remained at that depth. The frost has averaged 15° in the night and 4° during the day continually. It appears rather giving way this morning (19th), as the lowest temperature during the night was only 5° below freezing. Negretti & Zambra's thermometers are used. Common Laurels, Sweet Bays, and Laurustinuses are quite killed to the snow line, and many Roses appear killed and others much cut; Celine Forestier and Triomphe de Rennes are quite dead. I daresay many other plants are dead,

as will be seen when the snow is gone. During the Christmas of 1860, the thermometer registered 44° of frost here.—Henry May, *Hope Nurseries*.

Poynton, near Stockport.—I beg to enclose the readings of a self-registering thermometer, 4 feet from the ground, and in the shade :—

	Max.	Min.		Max.	Min.
January 5th.....	32°	.... 12°	January 13th.....	25½°	.... 13°
„ 6th.....	41°	.... 28°	„ 14th.....	22°	.... 10°
„ 7th.....	50°	.... 38°	„ 15th.....	28°	.... 10°
„ 8th.....	50°	.... 41½°	„ 16th.....	30½°	.... 23½°
„ 9th.....	45°	.... 37°	„ 17th.....	30½°	.... 20°
„ 10th.....	44°	.... 35°	„ 18th.....	31°	.... 14½°
„ 11th.....	36°	.... 28°	„ 19th.....	34°	.... 21°
„ 12th.....	28°	.... 18°			

—Filix-mas.

Killaloe, Co. Clare, Ireland.—The thermometer here is a self-registering one, and is placed about 5 feet from the ground, in a stand, such as was described some years ago in your Journal. The scale is, of course, Fahrenheit's. We generally suffer little here from hard frosts, and still less from snow, and the fall here this year has been trifling.

January 3rd	16°	January 16th	20°
„ 4th	20°	„ 17th	18°
„ 13th	22°	„ 18th	14°
„ 15th	16°		

The lowest temperatures previously registered were as follow: —1850, January 17th, 15½°; 1856, January 13th, 18°; 1859, December 20th, 18°—W. H. Mayne.

GARDENERS' EXAMINATION FOR HONOURS.

"A Subscriber" would be glad to know where he can find the rules and regulations for the examination of gardener lads, as he is of opinion that by encouraging the education of young gardeners an essential improvement would be effected in all branches of horticulture. His attention was called to the subject by the report of the "Gardeners' Examination for Honours" in this Journal. He would suggest that with these reports a list of the questions at the examination should be published (not the answers). The advantage of this to future candidates would be to give them a notion of the subjects on which they would have to prepare themselves for examination

[We do not think it would be beneficial if the Royal Horticultural Society were to publish the exact questions that are put in the examination papers of gardeners for honours, but there can be no objection to publishing a syllabus of the subjects upon which the examinations are founded. We have, therefore, inserted below that which is published by the Society of Arts, and which is for all purposes the same as that on which the examinations of the Royal Horticultural Society are based.

"Floriculture.—Improvement of races in plants, by what means it can be commenced and carried forward. Hybridisation, objects of. Conditions necessary to ensure fertility in flowers.

"Warming and ventilation of houses for plant culture. Influence of ventilation on plants confined in forcing-houses. Limits of temperature endurable by plants, and how to turn this to advantage in practical floriculture. Bottom heat, value of in plant culture.

"Watering, the *rationale* of, in the culture of pot plants. Liquid manures, special recommendations of. Food of plants, how and whence derived, and in what form received.

"Propagation, the various modes of, and their special adaptations. Vitality of seeds, duration of, and how best preserved. Budding, Grafting, and Inarching, how performed, and to what subjects best adapted. Increase by cuttings and by layers. Leaf-cuttings, how is it that they can organise buds? Composts for various classes of plants.

"Acclimatisation. Is it possible to increase the hardiness of any race of plants, and what are the most likely means?

"The leading flowers of the different seasons, indicating those to be obtained naturally, and those by artificial means.

"Special Culture—Ferns, Orchids, Succulents, Heaths, Hardy Annuals, Bedding Plants.

"Text Books:—'Lindley's Theory and Practice of Horticulture' (Longmans). 'M'Intosh's Book of the Garden' (Blackwood & Sons). 'Thompson's Gardener's Assistant' (Blackie & Son).

"The Examiner, in his remarks on the work done by the candidates on the last occasion, says they 'fail most especially, as a rule, in conveying clearly and concisely the purport of their own replies, and lose force of expression by multiplying words. They are strongly recommended, as a part of their studies, to practise the writing out of short pithy remarks on each of the subjects set down in the programme, comparing their own remarks with the statements in the text books, and repeating this from time to time, cutting out all superfluous words, so that they may get the essential particulars well impressed on the memory.'

"Fruit-tree Culture.—Kinds of fruits adapted for various soils and exposures. The Propagation, Pruning, and Training of Fruit Trees. The Structure and Functions of the Organs of Trees, considered in their relation to growth and reproduction. The Forcing of Fruit Trees, and their cultivation under glass, both in and out of pots. The Theory of Ripening, and the principles that ought to regulate the preservation of fruits after they are ripe, or their subsequent maturation. The Packing of Fruit for transmission to great distances.

"Vegetable Culture.—The kinds and quantities of vegetable seeds and roots required for cropping gardens of given dimensions. The most approved mode of culture of the different kinds of vegetables and salads. The preparation of fermenting materials for artificial heating. The forcing of vegetables and salads.

"*General Subjects.*—Soils, Water, Atmospheric Air, Light, and Heat in their relation to the successful cultivation of fruit and vegetables. Manures and their application. The Diseases and Insects to which fruit trees and vegetables are subject, and their remedies. The erection, heating, and ventilation of garden structures.

"Text Books:—'Lindley's Theory and Practice of Horticulture' (Longmans). 'The Cottage Gardener's Dictionary' (Bell & Daldy). Hogg's 'Fruit Manual,' Third Edition (171, Fleet Street). Rivers's 'Miniature Fruit Garden' (Longmans). Bréhaut's 'Modern Peach Pruner' (171, Fleet Street).

"The Examiner, in his remarks on the papers worked on the last occasion, says:—'I am pleased to see the rising generation of gardeners devoting themselves to a study of the theory of gardening—to a study of those principles which ought to regulate every gardening operation, and without a perfect knowledge of which there can be no perfect practice. Practice without a knowledge of the principles by which it is governed is an insecure and baseless foundation on which to rest when natural conditions are disturbed or unexpected difficulties arise. I therefore urge on gardeners most strongly the necessity of studying the principles which regulate vegetation; but at the same time I desire also to see the fruits of that study exemplified in the practice, for a knowledge of the theory without the practice is worthless.'"]

ROYAL HORTICULTURAL SOCIETY.

January 15th.

Floral Committee.—There was a large attendance of the members of the Committee, but nothing for them to do. A single plant, from Mr. Howes, Seven Sisters Road, of a variegated Primula, was the only specimen sent. This was not worthy of notice, several plants of the same character having been known. The Committee seemed to be of one mind in lamenting the great losses many of them had sustained from the severe weather, the Roses and some of the Conifers having been entirely killed. The subject of the tobacco duty was again discussed, and as soon as Parliament meets some steps will be taken to obtain tobacco for fumigating plants at a low rate and on the same terms as that used for washing sheep and the Hop plant, when infested with vermin.

Fruit Committee.—Mr. Whiting, gardener to Mrs. Hope, The Deepdene, near Dorking, contributed nine sorts of Apples, for which he received a special certificate. Messrs. Slater & Sons, Malton, likewise sent a number of Apples, chiefly for the determination of the names; and from W. Wentworth Buller, Esq., Strete Raleigh, came several dishes of Court of Wick, intended, we believe, for distribution among the members attending the meeting. The only other subject worthy of notice was a bunch of Mrs. Pince's Black Muscat Grape, exhibited by Messrs. Lucombe, Pince, & Co., of Exeter, to show the extraordinary length of time for which it may be preserved. With reference to this property, as well as to the merits of the variety generally, remarks have already appeared at page 11.

General Meeting.—G. F. Wilson, Esq., F.R.S., in the chair. The business was entirely of a formal character. Sixteen new Fellows were elected, and the St. Ann's (Nottingham) Amateur Floral and Horticultural Society was admitted into union. On the table were placed a few subjects, not referred to as being brought before the Floral Committee. These were:—a variety of Sophronitis grandiflora called Alexandrina, and having purplish crimson flowers, from Messrs. E. G. Henderson; cut spikes of Barkeria Skinneri and a Lælia, from Mr. Hodges, gardener to E. Wright, Esq., Gravelly Hill, Birmingham; Zonale Pelargonium Minas, a promising variety, which received a second-class certificate last September, from Mr. Mann, of Brentwood; and from Messrs. Backhouse, of York, cut spikes of an Oncidium allied to O. serratum, with brownish green flowers having a small lip, and Brassavola cuspidata.

FINE CONIFERS.

I send the dimensions of seven trees of Wellingtonia gigantea, which are in the pinetum here. No 1 is 23 feet 4 inches high; its circumference of stem is 6 feet 2 inches, and it measures 18 feet 4 inches through the branches. No. 2 is 20 feet 6 inches in height; No. 3, 17 feet in height; No. 4,

17 feet in height; No. 5, 16 feet in height; No. 6, 16 feet 7 inches in height; and No. 7, a cutting from No. 1, 14 feet 4 inches high.

We have also some very fine specimens of Picea nobilis, Nordmanniana, and pinsapo, and of Pinus austriaca, strobus, and excelsa. Some trees of Pinus insignis are between 30 and 40 feet high. Abies Albertiana and A. Douglasii are about 30 feet high; and Brunoniana, alba, morinda, and Menziesii are about 40 feet in height.—H. Hickman, *Gardener to R. E. Thomson, Esq., Kenfield, Kent.*

SOIL FOR CAMELLIAS.

Seeing your reply in last week's Journal to "Senex" as to the best soil for Camellias and Azaleas, in which you recommend turf cut 3 inches thick and stacked with a layer of cowdung an inch thick between each layer of turf, to be turned in six months, again in three months, and another three months to elapse before it is to be used, and all the rest of it so thoroughly disheartening to amateurs—allow me to say a word or two by way of cheering up "Senex," for I am sure he must feel greatly depressed at the prospect of losing his Camellias by having to wait twelve months for soil to repot them in.

Last March I purchased a lot of neglected plants from a neglected greenhouse, and among the rest a very sickly-looking Camellia in a deplorable state of filth and wretchedness. Being desirous of ascertaining the colour of the leaves, after a thorough washing with soap and water I found it to be a compromise between green and yellow. This result caused grave doubts as to the soundness of my bargain; but feeling assured that there was appropriate advice somewhere in "our Journal," I went in for a read-up, and I saw that excellent article by Mr. Pearson published in the number for the 27th of last February, and in which he says, "After many years' experience I have come to the conclusion that turf from a sandy loam is the only soil fit for Camellias, and that the addition of leaf mould, peat, manure, &c., is always injurious." He goes on to say, "Cut the turf as thin as if it were intended for a grass plot; chop it, or, what is better, pull it to pieces, and use it the same day it is cut. In using so fibrous a material considerable pressure must be employed in potting, otherwise it will be too loose."

After giving three cheers for Mr. Pearson, and three groans for men who would recommend one-year-old ——, but never mind, I set to work, turned out my Camellia, shook out the sour soil and dead roots, and repotted it—in what do you think?—why, in fresh-cut turf, pressed it firmly down, and I should like you to see the plant now, the picture of health; its flower-buds, of which I had to take off at least a dozen, swelling beautifully, and promising a glorious show. But I suppose you will not insert this.—T. L. C.

[You see that we have not only inserted your communication, but one from Mr. Pearson on the use of fresh turf. It is a step in the right direction, and though decomposed turf is excellent for Camellias, the Editors hope to have it established that fresh turf is as good for them. Editors have to recommend what they know is successful.]

EARLY PEAS AND POTATOES.

My garden is of light, porous soil, is well protected from the north and east winds, and thoroughly drained. Its slope is to the south and west. In this garden were sown on the same day Carter's First Early, Sangster's No. 1, and Daniel O'Rourke Peas. From what I had read of the first I expected to have a crop almost before Sangster's or Daniel O'Rourke had formed pods; but the lesson taught me was that the old friends were true friends, for Sangster's and the well-tried Daniel O'Rourke yeilded many dishee before the first-named; and when the lazy first did come, it was not worth waiting for. The Peas were all grown upon the same plot of ground; the rows all ran from north to south, and received precisely the same treatment. Elevation above the sea 260 feet, and distance from the coast nine miles.

About six months after I entered upon my parish work a worthy farmer came to visit my garden, and having examined my flowers and my vegetables, exclaimed—"Well, your Reverence, you can beat me in all but Potatoes." All but Potatoes! Well, do you know, I did not like that "but," and I resolved next year there should be no "but;" and none there was, for my good parishioner declared my Potatoes unequalled in size, quality, and quantity. The secret was, I planted whole sets of medium Potatoes, which I had started early. The Potato was Myatt's Ashleaf.

Last year the greater part of the Ashleaf Potatoes were waxy and diseased, the Scotch Cruffles were nearly as bad, and the Early Heroes were worse.

Having tried many plans of Potato culture I thoroughly agree with "D.," of Deal, and Mr. D. Thomson, as to the advantage of using whole sets. As an experiment I disbudded a few sets, leaving only one eye, and was rewarded by an earlier and larger yield. The ridge system I should condemn as strongly as your last correspondent, provided the soil is light and dry, but the case is quite altered if you have wet, heavy ground.

I will give you, some time, the results of this year's culture.—Ronnoc.

THE ROMAN HYACINTH.

I want to say a word in favour of a little bulb which I do not think meets with the attention that it ought, I mean the pretty little Roman Hyacinth, believing that in another season some of your readers who are situated as I am will be very glad to make further acquaintance with it.

I have no means of forcing plants, my object being, as far as greenhouse plants are concerned, to keep them safe from frost. Those who can force will, therefore, probably think little of a Hyacinth like this, which is so much inferior in size and beauty to the Dutch varieties; but to me it is a matter of no little pleasure to be able to have at Christmas a pot of Hyacinths in full bloom, distributing their fragrance through the room, and that without any extra trouble. By forcing they can be had, I know, in November, but I think they are not nearly so pretty when forced as when grown naturally. It is a mistake, too, to plant them too thinly; they should be placed with the bulbs almost touching one another. I put six into a 32-sized pot, and have had them now for some weeks in bloom in my sitting room, their little snowy bells standing well up above the dwarf, stiff, glaucous foliage, and diffusing a pleasant but not overpowering odour throughout the room. Doubtless if they came in in March and April along with the other bulbs, we would not think a great deal of them; it is the fact of their blooming when they do that really gives them their value, and it is because of this I recommend them to those who, like myself, are obliged to study what is economical as well as pretty.—D., *Deal.*

[We are well pleased that our correspondent has noticed this fragrant little flower. It is a very old tenant of our gardens, being introduced in 1596. Formerly it was called Hyacinthus romanus, but La Peyrouse has founded on it a new genus, and it is named Bellevalia operculata.]

ENTOMOLOGICAL SOCIETY'S MEETING.

The first meeting of the year was held on the 7th inst., Sir John Lubbock, F.R.S., the President, being in the chair. Amongst the donations received since the last meeting were the publications of the Natural History Society of Geneva, contributions on American Lepidoptera, and on the Zygænidæ of Cuba, by Messrs. Grote and Robinson; on Danish Coleoptera by M. Schiodte; and Dr. Gerstaecker's annual review of entomological publications. A new part of the "Society's Transactions," containing papers by Mr. F. Smith on Brazilian Hymenoptera, Mr. Trimen on the Butterflies of Mauritius, and Mr. McLachlan on new genera of Psocidæ, was announced as ready for distribution among the members.

A memoir by Captain Hutton was read on the Japanese Silkworm, allied to the common Chinese Bombyx mori, which had been much overrated, and which he believed was only a hybrid between a sickly degenerate race of the latter insect and the little B. sinensis; and he expressed his opinion that the only way to renovate the European stock of Silkworms now so much contaminated with muscadine, &c., was to depute experienced entomologists to visit China with a view to the rediscovery of the Silkworm in its natural state of freedom.*

Professor Westwood exhibited a large collection of Heliconiidæ and Pieridæ from the interior of Brazil, collected by the late Dr. Burchell, whose entire collections had been presented to the University Museum of Oxford. They were extremely valuable, not only from

* Captain Hutton cannot have been aware that at the last International Exhibition at Paris some Silkworms and silk of a beautiful texture were exhibited which had been recently imported from Japan, and which had been found quite free from all attacks of the muscadine fungus.

the rarity of many of the specimens, but also from the fact that the precise locality and date of capture of every individual was recorded, so as to show most satisfactorily the extent of the geographical range of every species and supposed local variety. With reference to the mimetic resemblance between animals inhabiting different localities, he cited the instance of the humming birds of the New World and the Humming-Bird Moth of Europe.

Mr. McLachlan asked for an explanation of the fact that the last-named insect is frequently to be observed in considerable numbers chasing up and down walls, banks, or cliffs, exposed to the hottest sun, and especially about stone walls near the sea, but no explanation was offered.

Mr. F. Smith stated that in consequence of this habit of the Humming-Bird Moth, a clay nest found upon a wall, over which the Moth had been seen hovering, had been sent to the British Museum, on the supposition that it was the nest of that species of Moth, but it was found to have been made by a Mason Bee.

Mr. A. E. Eaton mentioned that during the last season he had found the nest of the Hornet in an unusual position—namely, in a sand bank, where there was no wood near.

The following memoirs were read—Chorentidæ and Crambina collected in Egypt in 1864, and Crambina, Pterophorina, and Alucitina collected in Palestine in 1865 by the Rev. O. P. Cambridge, determined and the new species described by Professor Zeller, the German descriptions translated by H. T. Stainton, Esq; and a monograph on the genus Hestia, with a revision of the Danaidan Butterflies—namely, ninety species of Euplœa, seventy of Danais, and ten of Hestia, by Mr. A. G. Butler.

OUR VINES.

(*Concluded from page* 50.)

So we came to the autumn of another year, and the yellow leaves fell from the great Sycamore tree in the garden close by, and the Silver Birch threw its long shadows on the grassy lawn, and our fruit, yet untasted, hung ripe and ripening in the vinery. It seemed as if we had come to the very point, reached the end for which we had aimed and worked, as if our land of promise lay all before us ready to enter in and possess, as if the reward had come for all our care, and thought, and work, and study; not the reward of so much pleasure or enjoyment, or eating, or giving away to friends, which though last is not least; but that deeper, richer, better, more lasting reward, success to our efforts, the power expended coming back to us in a larger measure, giving us a sense of knowledge we could never more part from.

"You are not out of the wood yet, with all your shouting," said Cousin Walter, one Saturday afternoon in October, the day appointed for the first fruit-gathering, and our Vine doctor had promised to come over and help in the arduous work.

"What is the matter Walter?" said Cousin Herbert, "Why there is mould, and no mistake, upon these berries," and he was rubbing away with all his might at a bunch of Lady Downe's.

"Come up and see for yourself, Kate."

"It is not mould, it is the very bloom you are rubbing off," said Kate in great alarm, "Come down this minute."

"You do not mean to tell me this mealy whitey-blue stuff is bloom do you? why the very canes are covered with it."

"So they often are on Lady Downe's," said Kate.

"You are a jackanapes, Walter," said Uncle Tetley, "if I were you, I would not meddle with what I did not understand."

I do not think we should ever take a prize for Grapes, even if we were to try, and they were never so fine, said Uncle Tetley, we handle them so much."

"Well, you see they are our first," said Cousin Herbert, "and a great deal of pleasure lies in the touch; they are something like a first baby, much made of and tossed about. The idea of a Greek scholar rubbing the bloom away from his Grapes, thinking it mould. But if there is no mould, which I am not sure about, there are plenty of thrips on that Reeves' Muscadine, you can find them by hundreds, if not thousands."

"Never mind the thrips, said our Vine doctor, coming in just then, let the thrips die with the dying leaves. You can do nothing, you can neither syringe, nor smoke, so you must do as you say here in Yorkshire, 'bide your time.'"

"Well you may laugh," said Kate, "but I expect some morning we shall find the thrips has carried everything out to the lawn."

"Then I will help you to bring them in. Bless my life you have in comparison none, half the gardeners in England would swear they had not, if they had no more. I tell you what, Miss Kate, I would not like being your gardener, no not for a thousand a-year. Come now, what about those bunches, which are we to cut, and what are we to do with them?"

"Think of your friends to be sure," said Aunt Margaret, "no good will ever come of them if you are stingy."

"Well, I suppose," said Cousin Herbert, "the largest must go over the way to Mrs. Arthur Tetley's; or, perhaps, dear Aunt, you will not mind taking it with you; and, then, George must come in for a share, for after all his queerness, I have seen him give many a helping hand on the sly."

"And, then," said Kate, "Papa says Dr. Brown must have a bunch, for he does not grow them, and is very fond of them."

"And you would not forget our Rector," I said.

"No need to think of him," said Janet, "look at all the people in his congregation who have vineries, and, doubtless, will send. Why I dare say he has more than he can eat."

"And, then," said Cousin Walter, "there is lawyer Forden, he must have, or all the fat will be in the fire."

"And there is Walter's learned schoolmaster," said Uncle Tetley. "And, then, there are neighbour Cuthberts."

"No need to think of them," said Janet, "they are rich, and can afford to buy."

"I dare say all the people we have mentioned can do that," said Kate. "After all it is only an expression of kindly neighbourly feeling."

"It looks as if you thought such a deal about them, as if you had never had Grapes before, and were proud of them, and wanted to be thought clever."

"Well, we do think a great deal about them, Janet, we are very proud of them, and we have never had before of our own growing; and there is another thing, we are not ashamed of our feelings, nor of showing them. I wonder what they were given us for, if they are always to be hid away."

Then we had great work with our Grapes, cutting them down, bunch after bunch, some weighing more, some less than we thought. Cousin Walter held up our little rubbish-basket for their acceptance, but Cousin Herbert shook his head, saying, "Nay, nay, that will not do, we must have something better and cleaner." Then Aunt Margaret brought to light from some place where it had been hid, where we never could make out, a beautiful silver basket and Grape-scissors, saying in reply to our exclamations, "Oh, never mind where it came from, it is a present." If we have not a first-rate gardener, that is no reason we should not serve up our fruit in a decent, proper manner. Then in triumph we bore into the dining-room our silver basket heavy with its own worth, heavier still with its weight of Grapes, and we formed a jury, and sat in judgment on them round a blazing fire.

"These Black Hamburghs are very good," said Uncle Tetley.

"I think them splendid, would not desire better," said Papa.

"I like Reeves' Muscadine best," said Cousin Walter, bobbing one after another of the little round berries into his capacious mouth.

"I do not," said Mamma, "really, Herbert, you must send me over some Muscat Hamburghs, they are my taste."

"They are, indeed, very delicious," said Kate, "I would rather have one bunch of Muscats, than a dozen Black Hamburghs."

"Well, Lady Downe's is my favourite, there is something sparkling, something piquant about her, and then, too, there is a substance about the berries not like so much sweetened water."

"They are very good," I said, "with one great fault, rather-moreish."

"Janet you eat away, but do not say one word," said Aunt Margaret.

"Oh, Janet is thinking deep waters do not bubble as they run," said Cousin Walter.

"They are very good," said Janet, "but I have eaten better."

"I never did," said our experienced Vine doctor, "and many a professional grower would be proud to show such. In one respect, though, I think you have missed it, Mr. Herbert, you should have kept an accurate account of cost and return, valuing your pleasure at so much, then we might have had some idea how your bank book stood."

"I assure you I dare not do that," said Cousin Herbert, "for cook says they have burned no end of coals and cinders, and Maud and Kate would have brought in heavy damages for spoiled Merino dresses and soiled skirts. Next year, if all is well, I will try to do so, and then we can weigh the worth of our Grapes against our coal bill."

Then Mary, our little helper, came in for her share. "These are for yourself," said Aunt Margaret, "and the others for cook and Martha."

Cook said, they looked very well, but she didn't mind much about such things, they were a great bother; she would

rather have a mug of beer, or a cup of strong tea any time; and after all, Martha, "I don't believe they are all right, for they 'ave left more than half on their plates, maybe they are mouldy as Master Walter said."

"Oh! no," said the housemaid, "quality never eat the skins."

"I eat all," said Mary, with a glowing face, "both skins and stones, they have cost too much to waste."

So we came to the end of the third year, and the day of our great fruit-cutting was the anniversary of the planting. We left many bunches to hang until Christmas, until the new year, if they would keep so long. We sent many bunches away to friends near and distant, and the packing up with great care of those little fruit-baskets was a real pleasure to us, as great, nay, I think, almost greater than the receiving of such would be to us.

"That is right, Kate dear," said Aunt Margaret, coming in as we ticketed our last basket to a lame boy lying ill, "never forget the old, the poor, the sick, nor the unfortunate, gifts to such come back to the giver with a blessing."—Maud.

OLD ORCHARDS IN KENT.

I have been expecting some one to say more respecting the Flemish Apples and Cherries, and the subject so much the more interests me because I came from the very parish Mr. Robson names (Teynham).

I will take as my station Frognell Farm, in the parish of Teynham. When I was a boy I well remember some old Flemish Cherries there in an orchard adjoining the homestead, called the Cherry Orchard; but the Flemish Pippin was chiefly in an orchard called Siller Hill, in Green Street, in the parish of Linsted, adjoining that of Teynham, and on the other side of the road in orchards belonging to F. Barling, Esq., who grows, I believe, all the sorts of Apples, Pears, and Cherries worth cultivating, but the age of the trees I am not at present able to give. My father says when he first went to live on the Frognell estate, about sixty years ago, there were some old Flemish Cherries there then, and I believe, if not recently removed, they are there now; but we must not expect to find trees in places where they are grown for profit after they cease to bear a good crop. At some future time I will give a more satisfactory note on them, after writing to the managers of the orchards of the above-named places.

I cannot but think that the place spoken of by Mr. Robson must be Frognell, or somewhere thereabouts. I will state my reasons for thinking so. In a little orchard on the other side of the road from the Cherry orchard used to stand the ruins of a building called the Moat House. It had a moat round it, but this moat was partly filled up about forty years since. A few years ago the railway went through this little orchard, and I do not know whether any traces of it are left. Not more than 100 yards from the Moat House stood another old building called the Old Bedlam: this building was pulled down about sixty or seventy years ago. The oldest building that I know of standing there now is what is called Frognell Great Barn. I forget the date of it, but I believe it is two or three hundred years old. Another field near Teynham church, about a mile from this place, is all foundations, and in one place is a well, which is now arched over. It appears to me that centuries ago these places must have been of some note.—G. Holmes, *Stroud, Gloucestershire.*

JOURNAL OF THE ROYAL HORTICULTURAL SOCIETY.

The fourth part, just published, completes the first volume of the New Series, and, like its predecessors, is deserving of high commendation. We have heard a complaint that the contents do not embrace a due proportion of practical gardening; but we cannot assent to that complaint. There are abundance of sources whence information on practical gardening may be derived, and the pages of the Society's Journal are better occupied with such relative information as is afforded in the present part by Mr. Berkeley's notes on Orchid Fungi; Professor Goeppert on the Breslau Botanic Garden; Mr. Hadwen's experiments on Temperature, and Dr. Masters on Double Flowers of Primula sinensis.

Mr. Bateman contributes a brief note upon an Orchid-pot, made of earthenware, in the form of a tree's branch, on which he finds Orchids grow as well as on a natural branch, while the disadvantages consequent on the decay of the wood are avoided.

CALIFORNIAN ITEMS.

At the recent State fair at Sacramento, J. Q. A. Warren, of Sacramento, who has travelled extensively among the Sandwich Islands, showed "a collection of Sandwich Island Ferns and flowers, embracing over five hundred specimens of beautiful texture; cabinet woods of the Islands highly polished; seed and seed-pods, very curious; Sandwich Island Cotton in the boll and loose; samples of Sandwich Island Rice in the paddy, cleansed and polished; Poi Calabash and Water Calabash; silk cocoons of immense size, raised by himself at the Islands from eggs furnished by L. Prevost; Coffee, Castor-oil Bean, Bread-fruit, Ginger, land shells of one hundred varieties, and a large collection of Island curiosities."

We also learn from copious reports in our San Francisco and Sacramento exchanges that the fair in most respects was a great success. The wonderful growth and yield of all the cereals, fruit, and vegetables, has ceased to be a wonder and topic of remark, and all attention is being turned to new topics. The state is already becoming famous for wool and wine, as we see the wool quoted in all our eastern markets, and meet the wine at all our principal fairs and on the shelves of the druggists. Cotton and silk are now attracting much attention in California. We take from the *Sacramento Union* the following items of objects at the fair.

"L. Prevost, of San Jose, has a large collection of silkworms on exhibition. In fact, silk culture, from the early stage of the worms feeding on the Mulberry leaf to reels of silk itself, is represented in this gentleman's exhibit; and the following extract from a private letter to him will show that a still more advanced stage will soon be added. Under date of San Francisco, September 17th, 1866, Meyer & Neumann say: 'Perhaps you will perceive in to-day's *Alta*, that we finished a small piece of rep, but the machinery not being in proper working order yet it is not of that quality which we intended to exhibit at the State Fair. Nevertheless, one of us will come to Sacramento the day after to-morrow, and bring the sample along with him.' Many of the cocoons exhibited by Prevost were raised from eggs furnished to him by different parties."

The Oakland Manufacturing Company exhibit two pieces of cotton sheeting as samples of the first hundred pieces, two as samples of the first thousand pieces of 40 yards each, and two of cotton shirting as samples of the first hundred pieces of 40 yards each, manufactured in this State. The mill of this company wove its first yard of goods on the 1st of December, 1865, and has been in active operation the most of the time since. The company have paid from twenty-five to thirty cents. per pound for cotton, and manufactured it into goods at an expense of fifteen cents. per pound. The mill is located in the village of Clinton, Alameda county. Among other cotton they have worked up a small lot of the variety known as the green seed, which they found to be equal, if not superior, to the Tennessee and Georgia upland cotton. With the experience of the past for a guide, a great improvement is expected in the present and future crops. They confidently expect that the cotton-growers of this State will be able to furnish them with sufficient raw material to keep their manufactory in constant operation. They have just entered into a contract to furnish twenty thousand yards of manufactured cotton for exportation to Mexico."

Hop Culture.—The *Alta's* correspondent says:—"No branch of agriculture pays better than Hops. For brewers' use the Hops of California have double the strength of any imported. We visited the Hop vineyard of Flint & Haynie, on the flats of Norris' ranch, American river, near Sacramento, recently. It covers twenty-five acres, and was planted in February and March of this year. The vines stand 8 feet apart. It is well demonstrated that short poles and cross-trailing on connecting cords, produce better crops than high poles. The crop for this first year is 24,000 lbs., worth at seventy cents. per lb., 16,800 dollars. Next year the plant starts from fixed roots of one year's growth, and the crops will double. It will be seven years, probably, before the plant will show deterioration."

Castor-oil Beans.—The Castor-oil Bean has been grown the present year (1866), to a much greater extent than is generally understood, and from the success of the present year we think the growing of the Bean and the manufacture of the oil from it may be said to be successfully begun.

The Northern District Fair of the present year, can claim

the credit of making the first exhibition of the Castor-oil Bean in any quantity. There was a large sample of nearly 100 lbs. exhibited by J. D. Blanchar, Esq., grown near Marysville.

We obtained the following statistics:—Dr. McDonald has this year one hundred acres of Castor-oil Beans. Mr. Chas. Justice has a field of five acres. W. H. Drum and many other persons have grown a greater or less number of acres, and this beginning has given assurance that the work that thus began will be continued, and the Castor-oil Bean and the oil from it will ere long be numbered among our valuable exports.—(*California Farmer.*)

PEAR CULTURE.

(*Continued from page* 51.)

PRUNING AND TRAINING.

Espalier or Horizontal Taining.—Commencing with a maiden tree, which is one that has never been headed or cut back, it will have a clean, straight stem, and be moderately strong, or rather such trees are to be preferred, as the buds are not so widely distributed. It should be planted carefully and early in autumn after the leaves begin to fall. If they have fallen, or from the fall of the leaf to the middle of February, or beginning of March, during mild weather, the tree should be cut back to within 1 foot of the ground, always cutting from the back of the bud, as shown by the bar at *a*, *fig.* 3, indicating the cut. This will be the commencement of the first season's pruning.

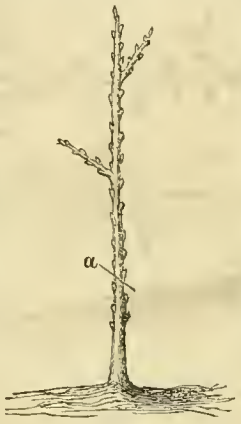

Fig. 3.

Shoots will be produced in spring from the three uppermost buds, that situated the highest should be trained upright, and the other two respectively to the right and left, and as nearly at an angle of 45° as can be; only if one grow stronger than another depress it, and raise that which is weak, so that shoots as nearly as possible of equal strength may be produced. This is a main point, and must be attended to; for if a shoot once be formed weak, it is difficult to render it equally strong with its neighbours, and a tree with longer shoots on one side or part than the other is neither pleasing nor profitable. This is the first season's treatment as regards pruning and training.

In the autumn the appearance of the tree will be somewhat similar to that represented in *fig.* 4, and the upright shoot

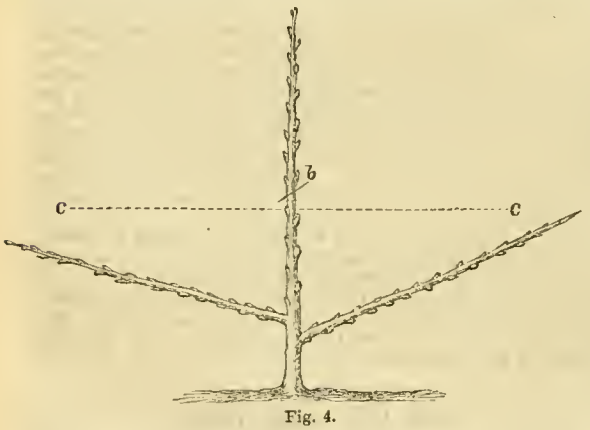

Fig. 4.

should be cut to within 1 foot of the point at which it was first shortened, or as near to that as a bud with two buds below it eligible for horizontals will permit. It should be remembered at the time of shortening the upright shoot, that 1 foot is the distance to be allowed between the horizontals; therefore, they, or the buds left to produce them, should be a little below the line along which they are ultimately to be trained. This will be readily understood on reference to *fig.* 4, in which *b* is the place where the upright shoot is cut, and *c c* the horizontal line. As the side, and particularly the lowest branches (it is usual to term a shoot of the current year, and until it produces secondary shoots a "shoot," but afterwards a branch when it produces side shoots, whether headed or not), cannot be too strong they should not be depressed or brought to the horizontal line for another year; and any shoots they may produce should be allowed to grow unchecked, unless they become too strong for the leaders, when they should be brought back to six leaves. The leaders of the side branches and upright are not to be stopped, but should respectively be carried to the right and left, and that of the upright in a vertical direction; and the side shoots are to be trained at an angle of 45°, as in the first season. The shoots or laterals from the two side branches, if stopped at the sixth leaf, may shoot again; these are not to be stopped for the present.

Fig. 5.

In the autumn of the second year the tree will somewhat resemble *fig.* 5. The leader or upright shoot should be cut back to *a*, in the same way as it was in the preceding season, and the laterals, *b b*, shortened to two eyes, and to not more than an inch in length. The shoots upon the side branches will come from the eyes left on the lateral wood. Such shoots are to have their points taken out when they have made six leaves, and sub-laterals being produced from them, such are to be stopped at the third leaf. The side branches may remain for another season at an angle of 45°; that, and the laterals not being close-pinched, will secure for them more vigour than were they trained horizontally, and the laterals closely pinched. The bars show where the knife is to be used.

In the autumn of the third season the tree may have the lowest pair of side branches brought to the horizontal line, *fig.* 6, *a a*, those of the last year's production still being retained at an angle of 45° for another season, when they are to be brought to the horizontal line, the leader or upright being cut back as before to furnish the leader and side branches of the following year. The side shoots, *b b*, are not to be shortened, nor the growth or leading shoots of the side branches, *a a a a*, in this or subsequent seasons, until they reach the limit of the space they are to occupy. The laterals, *d d d d*, must be cut in to two eyes or buds in this and all subsequent seasons, but the very short, stubby growths about an inch in length, and which produce a tuft of leaves, are never to be cut, but should be left at their full length. These are spurs upon which the fruit of the Pear is produced, and are represented at c c, in *fig.* 5, and *e e e e*, *fig.* 6.

The following year's treatment is simply a repetition of that in the preceding one; the two side branches produced in the previous season are to be brought to the horizontal line, and those of the year allowed to grow at an angle of 45° for a twelvemonth longer, when they are also to be brought to the horizontal line. In after-years, stopping the laterals, shortening in autumn to two buds or an inch, heading down the upright shoot, training in the side shoots at an angle of 45° for two seasons, and subsequently bringing them to a horizontal position, should be persevered in until the upright reaches the top of the wall. When the tree attains nearly the height of the wall, it will not be convenient to train the side branches at an angle of 45°, neither is it desirable, as they will acquire

sufficient vigour; therefore, towards the autumn of their production, they may be trained horizontally.

The above is undoubtedly the simplest mode of forming horizontal trees for walls or espaliers, as once the horizontals are started there can be no doubt in training them. The growth is easily under command, the sap equally distributed, the branches equally exposed to light, and though the distance of 1 foot between the horizontals may seem great at first, it is not more than is necessary for the full development of the leaves and spurs, their due exposure to light and air, and the proper maturation of the fruit. At 9 inches apart the side branches or horizontals more thickly cover the wall or espalier, but at that distance the wall is so completely covered with foliage that the sun's rays never reach it, consequently no heat is ra-

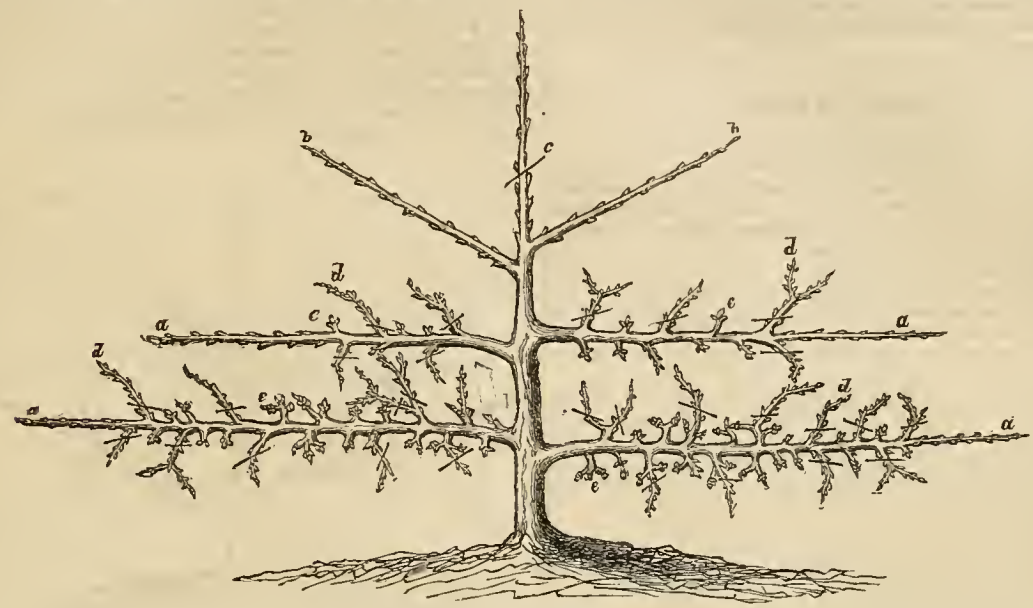

Fig. 6.

diated to the benefit of the tree in cold seasons; and in the case of espaliers the side branches at 9 inches apart so overcrowd and shade each other, as to prevent the proper development of foliage and perfection of fruit-spurs. 12 inches is the distance to be recommended between the horizontals, both for walls and espaliers.

The height to be recommended for espaliers is 6 feet, the first pair of horizontals being 1 foot from the ground. The rails should be of wire, and the upright and straining posts should be of iron in preference to wood, on account of durability. The uprights or supports may be let into stones about 2 inches, and run in with lead. They should be midway between each pair of trees, as the branches are more rigid near the stem, and have its support, besides which they seldom bear so large a quantity of fruit as nearer their extremities. No. 8 wire is the most substantial, though No. 12 will do. Both supports and straining posts should have four coats of oil paint; red lead is the most durable for ironwork.—G. Abbey.

(To be continued.)

NOTES AND GLEANINGS.

A rumour having been in circulation that Mr. William Bull had become the possessor of Mr. Standish's new Hermaphrodite Aucuba, we are requested to state that there is no foundation at all for the statement, that the Aucuba is in the sole possession of Mr. Standish, and that he does not contemplate, nor ever has contemplated, disposing of it, until he does so to the public generally in the ordinary course of trade.

—— At a meeting of the Quekett Microscopical Society, Dr. Tilbury Fox, one of the Vice-Presidents, read a paper on "Human Vegetable Parasites." The author's chief aim was to elicit from the members information in regard to the part played by Fungi in the production of diseased conditions of plants, men, and insects, and he confined his remarks to the following points: First, the probability of the frequent existence of the germs of fungi in the textures of healthy living beings, and in situations to which the external air has no access; the modes by which fungi effected an entrance to those spots; the fact that parasitic germs enter the systems of plants and animals at a much earlier date than is generally believed, through the soft textures of the young tissues; that fungi lie dormant a long time in the system, until favourable conditions occur to promote their growth; that fungi only become sources or inducers of disease when they develope to an undue amount; that fungi will not flourish on a healthy surface; the distinctive features of vegetable and animal structures, especially artificial germination; and the effects, chemical and other, produced by the growth of fungi. Dr. Fox illustrated all these different conditions by a reference to the phenomena of "ringworm" and allied diseases. Mr. M. C. Cooke gave a number of very interesting facts in reference to the parasitism of plants, entirely confirmatory of Dr. Fox's observations; detailing cases in which the germs of mildew and rust must have entered very early indeed into plants, and even been contained in the seed, developing as the plant grew up; also where the elements of rust entered through the first pair of young (cotyledonous) leaves. He also stated that he never looked for parasitic fungi on those plants that appeared vigorous and healthy, but was sure to find them on those which looked sickly or grew in unhealthy places.

—— With very great regret we have to announce the death of Mr. B. P. Brent, to whom our readers have been so often indebted for useful information in our pages. Mr. Brent edited for us "The Pigeon Book," and "The Canary and Other Song Birds," the subjects of which he well understood. Mr. Brent died at his residence Parkhurst House, near Uckfield, Sussex, on the 18th instant.

WORK FOR THE WEEK.

KITCHEN GARDEN.

Where the soil abounds in silica, or is what is technically termed too sandy, procure, if possible, a quantity of clay and spread it from 2 to 4 inches deep over the whole surface of the soil, allowing it to lie for a time that the air and frost may pulverise it, when it may be dug in, and it will very much improve the ground. The use of sand in the same way where the soil is a heavy clay will likewise be very beneficial. *Capsicums*, seed of the large sort should now be sown in pans or

pots placed in heat; as soon as the plants are an inch or two high, put them in small pots and replace them in heat; afterwards shift them when necessary, until the end of May, when they may be planted out on a south border. *Cucumbers*, the plants in bearing in the forcing-house should have a top-dressing of fresh rich soil; use every means at command to keep them free from insects. When the young plants in the seed-bed have made one rough leaf, the leading bud above it should be removed so as to cause the plants to throw out two shoots from the axils of the seed-leaves. Cuttings put in and struck in the seed-bed will come into bearing quicker than seedling plants. *Herbs*, keep up a supply by introducing some potted plants into any forcing-house, or into a frame or pit where there is heat. *Lettuce*, sow Green or Brown Cos in shallow boxes placed in any situation where there is a command of heat. This sowing will only be necessary where there is a deficiency of autumn-sown plants, otherwise no seed need be sown till the middle of next month. *Potatoes*, plant in pits or frames where there is a slight bottom heat; the sets should have been previously laid in a forcing-house to shoot. Sets may be planted in pots to be placed in any convenient part of a forcing-house until the shoots are several inches high, when they may be planted in frames, but we do not much approve of this plan as we have found it result in a deficient production of tubers. *Tomatoes*, sow seed of the Large Red immediately, so as to have good plants when the weather shall permit of their being turned out.

FRUIT GARDEN.

It is now a good time to wash fruit walls, and we would strongly recommend our readers to do so, particularly walls against which Peaches are trained. The washing should be done before the trees are pruned, as if a few buds are rubbed off it will not be of so much consequence as it would be after pruning. A good mixture is composed of lime, sulphur, and soot, brought to the consistence of paint with strong soapsuds. About 1 lb. of sulphur should be used in every pailful of lime after being mixed with the soapsuds and sufficient soot to give it a dark grey colour. The trees should be tied from the wall and the mixture laid on with a whitewash brush. Prune and remove the suckers from Filberts, which rarely, except in Kent, are managed as they should be. The making of fruit-tree borders, particularly for the finer kinds against walls, requires the use of fresh turfy loam; let that, therefore, be in readiness. The only addition should be road scrapings, or something similar, where the loam is heavy, for the Peach and Apricot; use loam alone for Cherries and Plums, adding a small quantity of rotten cowdung for Pears, but not if the loam is rich. Dust over on damp mornings with soot and lime Gooseberries, &c., which are attacked by birds. Raspberries may have the old wood removed and the new shoots thinned. Leave the shortening of them till another time.

FLOWER GARDEN.

With the exception of pruning and thinning, or wheeling when the weather is frosty, little can be done in this department at present. Any of the shrubbery borders which may require a dressing of fresh soil or manure, should, however, be attended to whenever the weather is favourable for such work. Proceed with any alterations in hand involving the removal of a considerable bulk of soil, cutting walks, or anything which can be judiciously done now, in order to have the hands at liberty for the ordinary routine of spring work which will soon be demanding attention.

GREENHOUSE AND CONSERVATORY.

As the season is at hand when the business of increasing our stock of plants will demand particular attention, it will not be inappropriate to suggest the advisability of preparing a place calculated to afford the required convenience. There is scarcely a gardener who is not called upon to apply his skill to replace the losses that invariably and necessarily attend the occurrence of a rigorous season like the present, and yet we rarely find a proper situation appropriated for the purpose. For the plants principally in demand for decorating the flower garden, such as Pelargoniums, Fuchsias, and Verbenas, the common plant-houses are unfortunately found sufficient in many cases; and we see them crowded with pots of cuttings, to the destruction of all order and propriety, in addition to the insects which are often introduced along with them. What we wish to recommend is a small pit constructed with beds to contain plunging materials, and provided with a heating apparatus capable of supporting a bottom heat of 90°. This, with a complement of bell-glasses, would enable the gardener not only to raise his stock of summer plants with certainty and expedition, but give him the oppertunity of multiplying his rare and more difficult plants at the seasons most suitable to them. The unsettled state of the weather lately has called, and most probably will continue to do so, for much judicious management in regulating the temperature of large greenhouses. Naturally plants will make little pregress at this season, but they may he stimulated to unhealthy activity if attention be not directed to the regulation of the temperature. Eradicate scale and other insects from climbing conservatory plants, at the same time tie and arrange them. Care must be taken that Camellias receive no check, or their buds will be endangered. Brugmansia sanguinea, a noble conservatery plant, demands similar attention. In greenhouses it will be necesaary to examine softwooded plants in order to remove decaying leaves, and make an arrangement that will give them liberty to receive the full benefit of light and air.

FORCING-PIT.

No diminution of temperature must be allowed here. Pinks after they have made a little growth require to be removed to a cooler place, or the buds will fall. Gardenias require a warm moist atmosphere, which may now be slightly increased as they exhibit activity. Much care is necessary with Dutch bulbs, Hyacinths, &c., in removing them from the plunging material. If they are suddenly exposed to light a premature development will be the consequence. They should be placed in a somewhat dark part of the pit for a few days, and abundance of atmospheric moisture applied; on the last much depends.—W. Keane.

DOINGS OF THE LAST WEEK.

Never has the changeable character of our climate been more conspicuous than during the first fortnight of the year. The thermometer on the 3rd and 4th was close on zero as a minimum, up above 50° as a maximum in the shade on the 7th and 8th, and then swept down again from the 10th. The frost on the last of these dates, though scarcely so severe, was, from the absence of snow, likely to do more damage to young exposed crops of all kinds than the frosts preceding it. The little skiffs of snow which we have had, such as half an inch on the 14th, and as much more on the night of the 15th, will do something to mitigate the evil in this respect. Another favourable circumstance was that when the frost was unusually severe the atmosphere was very still, and, therefore, the cold did less to lower the temperature of houses and injure plants than a frost of scarcely half the intensity accompanied by a dry, searching, scorching wind that would find its way into every hole and cranny. The weather has been so exceptional that it would be well to notice a few simple matters which, owing to circumstances, occupied a considerable share of our attention.

Protecting Material.—Dry straw, litter, and old hay are invaluable for protecting purposes, and their value is greatly increased in proportion to their dryness, a matter which is very frequently forgotten, as, in uncovering, the men are very apt—say in the case of glass—to collect the covering in front of the frame or pit, just in the place where, if a shower come, the water will run off the glass and into the covering. This is not of much importance if that covering is to be turned into fermenting material, but is of great moment where there is, as in most places, a difficulty in procuring dry material, and not without paying well for it. It would be easy to avoid this by placing the covering in little heaps where the rains would not wash into it or into the base of the heaps, and thus be raised through the whole by capillary attraction. Without much trouble such little heaps cannot be defended from the rain that falls, but if thrown together like little haycocks, it is only the outsides that will become wet; and very little practice will show the great difference between dry and wet litter in excluding cold, and that which is much the same, in excluding heat.

Owing, we believe, to the comparative stillness of the air in the severest frosts, and the somewhat dry state of the litter, we have never known such hard frosts kept out by such a small amount of covering. Sometimes in a very sharp morning, when at first sight we thought it would be prudent to shake up the surface of the covering, and thus break the lines of radiation and conduction, and so force the frost to begin its work afresh on the surface, or even to add a fresh sprinkling to the surface, we have been saved either labour by examining and finding that the frost had not been able to penetrate the slender covering. Let us, however, add here that a covering of litter would be greatly increased in its protecting properties,

in proportion as its surface was frequently broken and turned so as to break the lines of the radiation of heat.

Since the second frost we had uncovered no cold pits and frames until the bright day of the 15th; and then, as the air was very keen, we merely uncovered a part of the glass to give the benefit of sunlight, and covered up again early in the afternoon. We were rather afraid that the cold places were a little too warm; but when, in the case of Cauliflowers under hand-lights, we found the plants were lying on the ground, both the ground and leaves crusted a little, we let well alone, and allowed the covering to remain on, knowing they were better as they were than if alternately thawed and frosted. Such plants will sustain no injury when thus slightly frosted if they be covered up for weeks, only they must not be uncovered until properly thawed, nor must they be exposed to a fierce sun for a few days afterwards.

It would not be safe to expose Calceolarias and the generality of the hardier bedding plants to so much cold as Cauliflowers, Lettuces, and Radishes will stand; but if these should be covered up days and weeks it is necessary that the atmosphere about them should be as much above freezing as to keep them safe, and cold enough to prevent anything like growth. An average of 35° under glass is good under such circumstances. In such a temperature they will not grow, and little moist vapour will be raised to create damps and their evils. In very cold dull days even Asparagus in a hotbed-frame was left covered-up, but in fine days it was exposed to the light; otherwise, from the heat below, the heads or shoots would be apt to be drawn and too much blanched.

Double Roofs or Sashes.—Except in the way of experiment we have had little practice with these, though recommending them to others. It would be very interesting to know how such large houses as the fernery of Mr. Bewley, near Dublin, behaved during this frost, as well as those belonging to other gentlemen who have given the system a fair trial, and that, where it was desirable to have a tolerably regular temperature and a somewhat equable degree of atmospheric vapour with the least application of artificial heat. We shall be surprised if these conditions were not more easily secured, and at a less expense for fuel, in houses with double sashes than in those glazed in the usual way.

The necessary amount of atmospheric moisture in such severe weather is most easily secured in common houses and pits by allowing the heat to fall, so that the plants shall be safe, giving what little air may be necessary at the highest point of the roof, and chiefly in sunshine, preventing sun heat and fire heat meeting and raising the temperature so much as to require much cold air to be admitted, and covering the glass of front sashes of houses and pits, however slenderly, so as to diminish the escape of heat from the glass, and thus obviate to some extent the necessity of large fires. In such weather in common houses, from which it is next to impossible to exclude the external air, more evil is done by admitting that air freely at the ventilators than in giving none at all beyond a little in the sunniest days, after the sun has affected the temperature of the house, and when, in expectation of its shining, the fires have been allowed to go out or become very low. The man who cannot be brought to study and consider whether there is likely to be sunshine early or not is not fit to take the management of houses, or of the furnaces that heat them, if the requisite amount of economy in fuel and labour is to be secured. Thus, as alluded to above, suppose that the mean temperature of a house in average weather is 70° by day and 65° by night; to maintain the house at that temperature in such weather as we have lately had would not only, if it were large, require a large quantity of fuel, but also a great amount of vapour to be thrown into the atmosphere, which vapour of itself would require additional heat to raise it, for the higher the temperature of the air the greater would be its capacity for moistnre; and then again the higher the temperature thus maintained, the greater would be the necessity for admitting cold frosty air in sunshine.

Let two facts be kept in mind, and then there will be less perplexity about firing and ventilating: First, there is no heat so good and so cheap as sun heat; and secondly, in every way it is mistaken policy to allow in plant-houses a strong heat from a fire and a strong heat from the sun to meet each other. In a common glazed house, with some openings between laps, &c., and in such a cold day as the 15th, but dull and without sun, we would have put on a small fire, and would have given no air except what found its way in in spite of us. In a dull damp day, with an average temperature of 40°, a brisk fire and moderate air-giving would do good by setting in motion a stagnant atmosphere; but we see no reason for making strong fires in cold sunshiny days that we may neutralise the effects by sending in huge volumes of cold, dry, frosty air, both processes being exhaustive of the plant's energies.—R. F.

TRADE CATALOGUES RECEIVED.

William Cuthbush & Son, Highgate, London, N.—*Catalogue of Vegetable, Flower, and Farm Seeds.*

Richard Dean (Assistant Secretary to the late International Horticultural Exhibition and Botanical Congress), Ealing, London, W.—*Catalogue of New and Choice Vegetable and Flower Seeds.* Though chiefly confined to novelties much care has evidently been exercised in their selection, and there are in addition useful descriptive and cultural remarks which will render this Catalogue what it professes to be, "A 'Welcome Guest' at the Gardener's Fireside."

B. S. Williams, Victoria and Paradise Nurseries, Upper Holloway, London, N.—*Descriptive Catalogue of Flower and Vegetable Seeds.—List of Choice Bedding and Border Plants.*

Hooper & Co., Central Avenue, Covent Garden Market, London, W.C.—*General Spring Catalogue.*

COVENT GARDEN MARKET.—January 23.

During the past week we have experienced a great falling off in the supply of rough goods, and the continued frost has compelled us very materially to modify the importation of French produce; still the prices are but nominally higher, and any increase would soon check the demand. Very few arrivals of Potatoes have been reported, and the best are worth more money. The trade in Broccoli from the west of England is almost suspended. Dessert Apples and Pears remain the same.

TO CORRESPONDENTS.

N.B.—Many questions must remain unanswered until next week.

Florists' Flowers, &c. (*G. Moss*).—There is no such work as you name. If you enclose sixteen postage stamps with your direction, and order "Flower Gardening," "Greenhouses," and "Florists' Flowers," they will be sent to you post free.

Garden Plan (*A. F.*).—Write to Mr. Gibson, jun., whose advertisement is in our first page.

Pine and Fir (*A Beginner*).—They are popular names, and are indiscriminately applied to the section Abietinæ of the Coniferæ.

Willows and Osiers (*Idem*).—These are all members of one genus, and the names are indiscriminately used in popular conversation. If any distinction is commonly attempted, it is by calling every tree Salix a Willow, and every Salix annually cut down for its rods an Osier.

Daphne odora Flower Buds Falling (*A Young Gardener*).—You have excited your plant into growth, and caused it to cast its buds, not having allowed it sufficient time to swell them; although they were not cast until a few days ago, they have probably been inactive for some time. You should place the other plant in a light, airy situation in a house with a nice, growing, rather moist temperature of from 45° to 50° at night. It will flower in due time. A temperature of from 55° to 65° by fire heat is too high.

Plants Injured by Fumigating (*T. S. L.*).—The mischief is to be attributed to your having used live coals for igniting the tobacco. The scorched leaves will for the most part fall, and the others will be so unsightly and so liable to mildew that we would have them picked off. Your plants will recover, though it will be some time before they do so. In future place a few pieces of charcoal in a fire, and when quite red use them instead of live coals for placing at the bottom of the cage, and put the tobacco upon the charcoal.

Sulphur and Clay for Vines (*Iota*).—1, The composition should consist of two-thirds sulphur and one-third clay, by bulk, with enough water to give it the consistency of paint. 2, It is very desirable to limewash the walls, adding to the lime one-third of its bulk of sulphur. 3, A mixture of lime and sulphur is not so good for painting the Vines as sulphur and clay, and we do not recommend it for such purposes.

Asphodelus Culture (*Idem*).—You do not say which of the species you have, but we presume it is hardy, and, if so, its treatment will be that of a perennial thriving in an open but sheltered sunny situation. Use a compost of sandy loam, mixed with one-third leaf mould. Give it a top-dressing of the same kind of soil every autumn, neatly pointing it in around the plant in spring.

Book (*Asparagus*).—"The Garden Manual." You can have it free by post if you enclose twenty postage stamps with your address. It is quite suitable to your requirements.

Hot Air from a Kitchen Range (*Rusticus*).—We are rather surprised that the opening of the usual valve did not help you a little, but they are generally too high-placed for the purpose. You have to some extent misunderstood what we said as to the position of the second hole we advised. According to your section you have a hole made for a two-inch pipe at the top of the left-hand side of the back of the oven, and what we advised you to do was to make a similar hole for a pipe communicating with the *bottom* of the right-hand side of the back of the oven. Hence, too, the necessity for the two plugs when cooking in the oven was required. We know the difficulty of arranging these matters when the mistress of the house has to be consulted, and, of course, the interests of the oven and of the greenhouse might thus often clash: therefore, we also proposed closing in a chamber over the oven, and taking the heat from that instead, but even then you would mostly lose the place above the oven for general purposes. The heat from the oven is not by any means lost in ordinary cases, as it greatly tends to warm the room. We think as you managed the first hole in the back of the oven, you might manage another, but at its bottom. If not, however, we would advise a small stove, iron or brick, for your glazed building. If the place is small you will obtain much heat from the chimney. We would do what we could to oblige.

Mrs. Pince's Black Muscat (*G. P.*).—It does not require so much heat as do the common Muscats, but can be grown in an ordinary vinery. It is a very robust grower, and abundant bearer, not requiring to be grafted.

Vines and Dwarf Kidney Beans (*C. S., Chichester*).—The house has been kept too close; more air should be admitted, and more moisture kept in it, and not so high a temperature either during dull days or during the nights. In the stage of growth which the Vines are now in, shoots 6 inches long and drawn, 75° by day and 60° or 65° at night should be the extremes.

Error.—At page 44, column 1, line 13 from bottom, for "south" read "north."

Chiswick Temperature (*Inquirer*).—The temperature recorded on the morning of the 5th inst. as the lowest during the preceding twenty-four hours is correctly given by us in our Journals of the 8th and 15th, as 11° below zero. You did not notice the *minus* sign preceding the figures on the 15th.

Black Currant Bud Insect (*W. T.*).—The Black Currant buds in the neighbourhood of Glasgow are at this season of the year infested by immense numbers of an exceedingly minute, undescribed, four-legged species of mite, which causes the buds to swell, and renders them unfruitful. We cannot advise any plan for the prevention of this injury, except that of picking off and burning the infested buds.—W.

Raising Hornbeam (*R. H. A.*).—Hornbeam is raised very abundantly by seed. Cuttings may possibly be struck, but that mode is less likely to afford good healthy plants. In Hertfordshire, where the tree is extensively grown as copsewood, it is customary to bend down some of the poles as layers when there is a lack of stubs, and by fastening them to the ground they strike root, but we think all the young trees are reared from seed. Its reputation as copse-wood is due to its making excellent firewood, otherwise as a timber tree it is of slower growth than the Beech, and never attains the size of that tree. It also cuts better as a coppice tree.

Uses of Frame (*Nemo*).—You may use your frame as you propose for raising Lettuce plants by filling it to within 12 inches of the glass with dung, and placing 3 inches of soil over the latter. We would make a bed of hot dung from 18 inches to 2 feet in height, and a foot wider than the frame all round; put the frame on, fill it to within 9 inches of the glass with hot dung, and on that place 3 inches of loam and leaf mould in equal parts, with an inch of fine soil over it. The bed should be made evenly and well trodden down, but not the soil. We would then, after levelling the surface, sow some Lettuce, Cauliflower, and Celery seed, appropriating one-third of the frame to each. The light may be put on, and kept close until the plants appear, when it should be tilted in mild weather until the plants show their rough or second leaves, for if the frame be kept close the plants will become drawn. When the air is frosty keep on the light, and protect at night with a covering of mats. The bed may be made in the last week in February or first week in March. The Lettuce and Cauliflower plants, when sufficiently large to handle, may be taken up and pricked off in a sunny sheltered situation. This will give those left in the frame more room, and by the time the Lettuces and Cauliflowers are cleared out the Celery will need pricking off, which may be done within the frame. You may use the frame in summer for Cucumbers, and in winter for protecting Cauliflower plants.

Making Vine Border (*F. S.*).—It would be well to make the border as much above the ground level as you can for dryness and warmth, and it should be 3 feet deep. If the subsoil is wet, clayey, and unfavourable, the bottom of the border should be covered with a thin layer of lime rubbish, slope from the house, and a drain should run lengthwise at two-thirds of the width of the border. The lime rubbish must be beaten quite firm, and two more layers of similar thickness laid on and rammed hard. Upon the concrete bottom place 9 inches of brickbats or stones, the roughest at the bottom. A layer of sods, grass side downwards, may be placed on the drainage, and the border may be composed of turf cut from a pasture, 3 inches thick, where the soil is a good hazel or yellow loam inclined to be sandy rather than clayey. This is to be chopped roughly with a spade, mixed with one-sixth old mortar rubbish or chalk, and one-tenth half-inch bones. The compost should be carried up to a thickness of 2 feet 6 inches, and may be beaten with a fork as the work proceeds, but under no circumstances trodden down. The border will settle down gradually. Thompson's "Gardener's Assistant" is a good work for general purposes, and may be had through any bookseller.

Camellias Propagating (*A Subscriber*).—Camellias may be propagated from cuttings, and, indeed, are largely propagated in that manner, but it is only the Single Red for stocks. The double kinds grow very indifferently from cuttings, hence they are grafted on stocks of the Single Red, which is the only eligible mode of propagation to secure a free-growing plant.

Watering Pelargonium Cuttings (*Celia*).—The plants with the leaves flagging and the soil in the pots dry, ought to be watered. Whenever the soil becomes dry, and the leaves of the plants are affected thereby, give as much water as will come through the pots. Water will not be necessary so long as the leaves do not flag, but in your greenhouse it ought to be given before they do so to any great extent. Water the plants at once, and again when they require it.

Evergreen Hedge (*H. A. Dixon*).—You may form a hedge at once of American Arbor Vitæ (Thuja occidentalis), by procuring plants 4 or 5 feet high; they are kept in stock at that height by the principal nurserymen. They should be planted 1 foot apart. This Arbor Vitæ will not do for a fence to keep out cattle. Privet makes a good hedge when planted alternately with Thorn, and it will do for an outer fence; so will Thorn and Holly, which make the best of all hedges. Arbor Vitæ and Yew make the best evergreen hedges, but Yew foliage is poisonous to cattle.

Apricot *versus* Peach Treatment (*A. Z.*).—Your gardener unnails your Peach and Nectarine trees, so that he may cut out the wood that has borne fruit in the previous year, and any old, worn-out, and useless shoots; also to give each shoot and branch its proper share of the space, and secure the proper covering of the wall. It is evident your gardener acts on the long-pruning system with the Peach and Nectarine. He does not unnail the Apricot tree, because the tree chiefly produces its fruit on spurs, and a branch once made continues to furnish fruit-spurs so long as it exists. He will nail in a young shoot where practicable, and occasionally cut out a spurless branch, training a young one in its place; beyond that he will not interfere with the unnailing of the tree, and consequently no readjustment of the branches and shoots is needed.

Forcing Vines (*A Suffolk Subscriber*).—To have the Grapes ripe by July it will be necessary to start the Vines the beginning of February. To secure this the border ought to be protected, and you will require fire heat from February to July inclusive: hence we conclude it would hardly be a profitable undertaking, considering the smallness of the house.

Annuals for Ornament and Bouquets (*H. F. F.*).—We are making inquiry, and will answer your questions fully next week.

Sowing Latania and Chamærops Seed (*Helen*).—The seeds may be sown singly in three-inch pots, in a compost of sandy peat, loam, and leaf mould in equal parts, adding one-sixth of silver sand. The pots should be well-drained, and the seeds sown so as to be covered twice their diameter with soil. The soil should be kept moist, but not saturated. The pots may be plunged in a hotbed of 90° if you have such, and, if not, in one of not less than 75°; the atmosphere should have a mean temperature of 70°. You will have to exercise patience in waiting for the appearance of the plants, for the seeds are slow in vegetating.

Camellia and Azalea Management (*A Novice*).—The Camellias and Azaleas will do excellently in your greenhouse from which frost is excluded. Give them a light and airy situation, yet free from currents of cold air, and water when the soil shows signs of dryness; but it must not be allowed to become so dry as to cause the foliage of the Azaleas to flag, and that of the Camellias to become limp, nor, on the other hand, should repeated and regular waterings be given when moisture is not required. Air should be given whenever the external atmosphere is mild, and protection from frost should be afforded. The above has reference to the winter treatment, which will continue in your case from September to May. After the plants have bloomed pot them if necessary. The house being cleared of bedding plants, the Camellias and Azaleas, if out of bloom, should be syringed morning and evening, and the floors, walls, &c., kept moist, so as to encourage growth. Air should be given early in the morning, but not nearly so much as during other periods, and the house should be closed early. The temperature being 55° at night, and from 75° to 80° by day, your plants will grow freely. They should have plentiful supplies of water when making new growths, also whilst in bloom. When the plants have made a good growth and show their terminal buds, or the Azaleas their points distinctly, discontinue the morning syringing, but continue the sprinkling of the floors, &c., and the evening syringing until the buds are formed, paying particular attention to the giving of air early in the morning, so as to have the foliage dry by the time the sun shines powerfully upon it. This treatment is to be continued until the buds are set, when more air must be given, and the house kept cool and moist, though twice as dry as when the plants were making new growth. They need not interfere with the bedding plants, for both only require protection from frost.

Names of Fruits (*Subscriber, C. P.*).—The Pear, Easter Beurré; the Apple, Court of Wick.

Names of Plants (*Edwin Taylor*).—1, Nephrodium patens; 2, Aspidium coriaceum; 3, Adiantum concinnum; 4, Nephrodium molle. (*G. B.*).—Ageratum glaucum, otherwise Eupatorium nitidum. (*K. T.*).—Dactylis glomerata, var. variegata. (*C. S. P.*).—Solanum ciliatum. (*A Youngster*).—You should send better specimens, and Ferns in fruit only. 1, Eranthemum leuconeurum; 4, Adiantum bispidulum. The other specimens insufficient. (*Pteris*).—1, Lastrea Shepherdii; 2, L. decomposita; 3, Asplenium sp. insufficient; 4, Aspidium coriaceum; 5, Pteris serrulata; 6, Sagenia sp. insufficient for identification. (*F. B.*).—Odontoglossum Ehrenbergii.

METEOROLOGICAL OBSERVATIONS in the Suburbs of London for the Week ending January 22nd.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

BREEDING GAME FOWLS.

The following observations will apply to almost all the different sorts of poultry in breeding for stock.

The great secret in breeding the best chickens for stock or for exhibition is, where many are kept, to have plenty of good cocks and young cocks, or "stags," as with few cocks and too many hens in proportion, the stock will always become weaker and weaker every year. Where only a few are kept, one good brood cock is only just sufficient for from two to six hens; and where many are kept, there should always be plenty of fine young cocks or "stags" kept running under the brood cocks, and breeding with them, one to every six hens at least, and then all eggs are good for hatching, and all chickens strong, vigorous, and healthy. With the Game more than one brood cock can seldom be kept, and, therefore, young cocks or stags supply the place of more.

Pullets should never be bred from, as they breed small and weak chickens, and their eggs are too small for hatching. Pullets should be kept separate from the breeding stock while breeding, entirely for laying eggs for household consumption, as being excellent winter layers. Stags or young cocks are also worse to breed from than full-grown cocks are; in fact, no fowls should be bred from until they have moulted twice, but where many are kept young cocks must be had instead of more old cocks, which kill one another with their spurs, which stags cannot do.

Good old birds will always breed far better chickens than very young birds will, and if strong and healthy it scarcely matters how old they are; for the younger hens so weaken themselves by frequent laying that their chickens are also weaker, and the older birds are less bred in-and-in than younger birds are, if the stock has been bred in-and-in; besides, the old birds have been proved as good before, which the young ones have not been.

The breeding stock should be selected with great care from the best shaped and strongest full-grown birds (not the largest), and irrespective of age, if only full grown or two years old. The brood cock must be especially good (never a stag), as more depends upon him than upon the hens as a rule.

The birds should be placed together for breeding about Christmas, so as to lay in February and not before, for hatching chickens in the last ten days of March and in the whole of the months of April and May, and not later, March cock chickens and April pullets making the best birds.

Early broods should have most cock chickens, and the later broods most pullets.

The eggs for hatching must be chosen with great care from the most pointed-shaped, smoothest-shelled, freshest-laid, and finest eggs, or eggs rather large or above the middle size, which are the best. The first clutches of eggs laid after moulting, if laid at the proper season, are the best for hatching; the second clutches are also good, but the third and following clutches are worse.

Eleven or twelve eggs should go to each sitting and never more, as a hen cannot brood or bring up more than twelve chickens properly to afford them proper warmth, the brood hens full grown of course.

The sex of eggs, it is said, may be easily ascertained by holding the egg, large end uppermost, to a lighted candle, or to bright sunlight through a chink in a darkish place, when if the air-bladder at the large end of the egg is at the top of the large end the chick is a male, and if at the side of the large end it is a female. In eggs of the same hen the more pointed are males, and the more equal-ended females; but different hens lay different-shaped eggs, the ovarium being of a different shape.

No Game hens should hatch-out chickens before the 21st of March, for fear of cold weather, nor after May, as too late in the year.

Long-shaped eggs are bad, so are too short eggs; small eggs are bad, so are rough-shelled eggs; equal-ended large eggs are also bad, being often double-yolked, and therefore unproductive. Eggs laid after a day's interval are the best for hatching, and all eggs should be marked and dated as soon as laid. The first eggs of each clutch should be rejected as too small, as also those laid after the hen begins to cluck or want to sit, as she then refuses the cock and is becoming unfruitful.

The more cock chickens in the broods the better, as their being numerous shows strength and vigour, and the pullets, though fewer, are always finer and better when there are plenty of cock chickens. At least one-third of each brood should be cock chickens, or the stock and the cocks are too weak and the eggs ill-chosen for hatching.

Crossing different colours in breeding is a very bad plan and only produces mongrel mixtures as a rule. Each colour should be kept separate, if there is room enough. Each colour should be crossed and bred with equally good or superior strains of its own colour, but, of course, as far removed in blood as possible. In breeding and crossing, the cock rules the colour, shape, and qualities more than the hens do, and the best chickens of both sexes take most after the cock, cock chickens more especially so, as a general rule. If crossing colours, therefore, the cock should be of the colour required. If breeding in-and-in put a first-rate old brood cock to your two-year-old hens, or a first-rate two-year-old cock to your best old hens, which will cross them a little. If crossing, breed from the best-shaped and strongest full-grown birds, quite irrespective of age. Spurred hens breed the hardest cocks as a rule. Pinkish-coloured eggs are laid by the red-eyed hens and produce the reddest birds, white eggs by the black-eyed hens, and the yellowish and yellowish-brown eggs by the yellow or daw-eyed hens. These last are the worst eggs. For stock choose red-eyed and black-eyed Game fowls of the very best shape, feather, and blood.

A dry soil and situation should be chosen for breeding, not cold nor too high, and never in the least damp. Wet and damp injure all fowls more than anything. The run should be sheltered from the north, and have sheds for shelter from rains from all quarters, and a little cover for shelter from the sun. A quarter of an acre at least is requisite for a good run, with grass, light gravel, coarse sand, and running water.

Young chickens should be cooped with the hen for the first twenty days, and then be let out to run about with her in fine dry weather, avoiding wet days and heavy dew, during which they should be kept in or near the sheds, and on dry coarse sand or gravel. The April showers are not at all hurtful to them, if not too wet or heavy. The perches should never be higher than 7 feet for Game fowls, and young chickens should not perch too early for fear of crooked breasts, as they are soft-boned. Young chickens should sleep on clean straw in pens, or in a large clean hamper, till of age to perch. The greatest cleanliness must prevail everywhere of course. Unspurred old hens are the best mothers. Game hens are excellent mothers. One level range of the perches is the best arrangement. Perches should be smooth and round, and of the proper size for the feet. Poultry-houses and runs should never be too much crowded.

Game hens average twenty days in hatching, and from their

hot blood often hatch at the end of nineteen days in warm weather. Red wheat and dry stale bread crumbs are the best food for young chickens; for fowls, barley in winter, and oats, peas, rye, and buckwheat at other times. Grass and clean water are great necessaries. Young chickens must have no damp food at all. Game are very hardy, and being hot in blood stand dry cold well. Poultry-houses should be of brick and tiled, not slated, and not too warm. Slate is bad.—NEWMARKET.

BRAHMA POOTRAS AT THE BRISTOL SHOW.

As an old friend, "Y. B. A. Z.," has virtually questioned the decision which gave to me the first prize for Dark Brahma chickens at Bristol, and, in fact, gone out of his way to depreciate my birds wholesale, perhaps I may in justice ask room for a line in defence of my pen, the more so, as I am, though a very old lover of fowls, comparatively a beginner in this breed, and exhibited Brahmas for the first time.

That our "Persian friend" is an admirer of vulture hocks both in theory and practice is well known; and most Brahma breeders also know that he has carried his hobby so far, as, in the opinion of all but those who share his views, nearly to ruin his own yard and some others crossed from it. While this point was yet undecided, while there was a chance of his gaining over the judges to his opinion, he, perhaps, did right to persevere; but now that the matter appears finally disposed of, and it is evident the judges will not have the hock he admires, it is rather hard that he should subject others who have shown more judgment to such one-sided criticism. Certainly any one reading his "Dottings" would suppose the first-prize pen was nearly bare on the shanks! whereas it is the fact that all three birds (which had very good combs indeed), were, and are still, well and fully feathered from hocks to toes!

Here I might stop, the simple fact that two such eminent Judges as Mr. Hewitt and Mr. Douglas placed my birds before a remarkably good and successful pen of Mr. Boyle's, which gained a first prize elsewhere a few days after, being, I should think, quite sufficient answer even to our Persian oracle. To say that I consider myself a good judge of Brahmas, and that I selected this pen with the greatest care, may also be beside the mark, but I will just state in addition to both that several of the most eminent Brahma breeders have complimented me on this my first success, and pronounced the pen by far the best shown this season in the chicken classes, especially in the dark colour of the breasts, which surpassed any birds I have ever seen.

I will only add that "Y. B. A. Z." himself had made several entries, and it was a subject of general inquiry why he did not send his birds. Had he done so we might have seen his notion of a perfect pen. A single cock he did send, but the bird had the misfortune to remain unnoticed.

With regard to the management of the Show generally, I would like to draw attention to the system of judging, which could not be too "highly commended," and which deserves to be universally known and followed. The two Judges were shown into the hall, and the feeder placed at their service to put together for comparison any pens they desired; but no one else, not even the Committee, was allowed. Thus they were enabled to make their awards in peace and quietness, and totally ignorant of and uninfluenced by all local interests. Every judge could testify how his arduous, and often thankless, labour would be facilitated were this admirable plan generally and rigidly adopted.—L. WRIGHT, *Southwell Street, Kingsdown, Bristol.*

THE SECRETARY OF THE POULTRY CLUB.

CONTRARY to my intention I have a word or two further to say concerning Mr. Zurhorst's attack upon me. It is a perfect matter of indifference what notice I had, or what assertions the Secretary may make, regarding my conduct as Honorary Treasurer to the Poultry Club. As I had nothing to clear I wanted no opportunity to clear myself. I asked none, and by what authority Mr. Zurhorst assumes that I had anything to clear I am at a loss to know. Had the resolution at Birmingham been brought forward by any other than a servant of the Club, I might probably have replied to it; but as it was done with no other intention than to annoy and insult me, I declined to notice it. Mr. Zurhorst, when he proposed the resolution, well understood the whole of the affair in question, which, with other matters he has for some time past been writing about, are, I believe, of as great indifference to the members of the Club as they are to me.

To reply further to Mr. Zurhorst's misstatements would take up more space than I choose to ask, and more time than I am agreeable to give. He, Mr. Zurhorst, has now got the Club into the hands he wished.—EDWD. TUDMAN, *Ash Grove, Whitchurch, Salop.*

[We cannot spare any more space for this controversy. It has been throughout one official of the Club insulting the other —"each willing to wound, and yet afraid to strike"—without leading to any result either beneficial to the Club or useful to our readers.—EDS.]

THE DISQUALIFIED GOLDEN-SPANGLED HAMBURGH AT WHITEHAVEN.

I HOPE you will do us the justice to inform your readers all about the disqualified cock at Whitehaven. The cock shown by us never had a hollow in his comb, he never had a large or small piece actually cut out of his comb designedly or otherwise, nor was the place ever sewn up again. Either of the Judges cannot but know, that the cock had never a hollow comb, for Mr. E. Hewitt has judged him seven times, and Mr. R. Teebay six times. To show your readers that the cock could not have had a hollow in the centre of his comb, or anything else to hinder him from prizetaking, we will just mention his career since August, 1866.

The first time he was shown was August 20th, 1866, at Mottram Show, where he took the first prize and premium prize for best pen in the Show, and was pronounced splendid by the Judges, Messrs. Dixon and Hutton. On August 25th at Halifax he was again first, and was pronounced by Mr. Teebay remarkably fine and well meriting the position; August 30th, Penistone, first prize again; September 1st, Keighley, first prize; September 4th, Barnsley, first prize; September 18th, Morley, first prize. Here he was called very good, and pressed closely for the cup. September 20th, Middleton, here to one of the pullets happened a misfortune, and the pen was passed over by the Judges. September 24th, Radcliffe, first prize; October 4th, Farnworth, highly commended, the pullet being out of condition; October 5th, Oswestry, first prize; October 10th, Long Sutton, second prize, Gold and Silver competing together; October 22nd, Wolverhampton, second prize. Some days after this he was sent on approval to Great Malvern, and on his return was on the railway from Saturday morning till Monday at noon without food or water, and was sent on the following morning, November 8th, to Ipswich Show as a single cock, and took the first prize. On December 12th and 13th at Ulverston Show he took the first prize, beating those that had beaten him at Farnworth: December 18th and 19th, Newport, highly commended; January 2nd, Bristol, highly commended; then Whitehaven, disqualified. Thus he made a total of eighteen journeys by rail, having travelled since he was first shown 3050 miles without a day's illness, so we will leave you to judge whether he is a mean bird or not.

As we are charged with having cruelly cut a large piece out of his comb, we shall make our defence, not by falsehood, as your correspondent has done, but by truth, and truth alone. All poultry exhibitors of any experience must know a bird's having travelled upwards of 3000 miles in a lined hamper, and being placed in heated exhibition-rooms, would spring his comb, and give it a tendency to fall over: this was the case, and before sending him to Newport his comb was a little inclined to one side, which we suppose was the cause of his non-success at that Show. On arriving home we put a stitch or two in his comb to hold it in its place whilst it got firm on his head again, and in the hurry he was sent to Bristol Show with the stitches in, and was not disqualified; they were allowed to remain in his comb, and he was sent to Whitehaven as he was, and disqualified. We must, however, say he was not sent to Whitehaven with the stitches in his comb with any intent to defraud or obtain a prize without having merited it, but by mere carelessness or neglect; but we feel hurt when we read that the cock's comb had either been "hollow or too wide, the poor bird's comb had actually had a large piece cut completely out of the centre of it." We wonder what a novice one must be to think of the idea of cutting a large piece out of a cock's comb that had already a hollow in the centre! and it must have been madness on our part to spoil a nice comb by taking a piece out of the centre. The cock is quite good

enough without having a piece taken out of his comb, or any such cruelty. We vouch that he never had a hollow comb, or had a piece taken out. All that was done was the stitch, as already stated; and we will give the person £5 who can show the hollow place in the centre of the comb, or where it has been, from the first time of his being shown to the last.

We do not find fault with the Judges for disqualifying our bird, for we are aware that they were justified in doing so, but we do not like the report, given in your Journal, that we had been so cruel. All that we want at the hands of any Judge at any show that we are exhibiting at is fair play and justice; we do not want a prize given to our fowls except they are worthy of it, and have merited it, and that shall always be the wish of —Samuel & Robert Ashton, *Mottram, Manchester.*

P.S.—Just as we send this to you we received information that our disqualified bird has been awarded the second prize at Kendal, against the best Golden-spangled Hamburgh breeders of the day. This must go to show the correctness of the above statements. At the same time we wish to say that all the stitches have been taken from his comb, and if we mistake not he will puzzle many a good bird before January is out, if justice be done to him, which is all that is wanted by us.

[The statement of Messrs. Samuel & Robert Ashton, in attempted refutation of your report, is certainly somewhat amusing, as perhaps by this act (entirely their own), a more confirmatory document of the cruelty really practised and complained of, on the comb of their Golden-spangled Hamburgh cock, could not have been produced, even had these two gentlemen purposely predetermined it, with the sole view of increasing the exposure of their own misdoings. The Messrs. Ashton refer to the mode of imposition practised as "the stitch;" and again, as one or two stitches, being put into the comb, not "with any intent to defraud, or obtain a prize without having merited it, but by mere carelessness and neglect;" and also that they shall make their defence "not by falsehood, as your correspondent has done, but by truth, and truth alone." Well, then, let the truth, so far as hitherto reserved, be told. At Whitehaven when "disqualified," three stitches were taken out of the cock's comb by Mr. Hewitt, and two by Mr. Teebay. Even then others still remained, and were permitted to do so, purely out of compassion to the feelings of the bird itself, as had ALL the stitches been at that time extracted, most probably the whole of the previous sufferings of this fowl—prior to the confirmed adhesion of the excised part—would have been reproduced, even as at the very beginning.

The Messrs. Ashton, as the owners of the bird, complain bitterly of the statement of your reporter, of their "having been so cruel," adding, "all they want at the hands of any Judge is justice and fair play." Every really conscientious exhibitor will undoubtedly feel grateful to the Judges at Whitehaven, Messrs. Hewitt and Teebay, for the fearless justice and richly-earned disappointment they meted out, as the proper reward of such acts as the Messrs. Ashton thus unblushingly avow themselves to have been guilty of—cruelties, alike incapable of either justification or palliation, and that tend more than all other duplicities put together, to bring discredit on a pursuit, naturally an innocent one, and one at the same time capable of producing both amusement and profit to all classes of society. —The Reporter.]

TAIL OF THE SILVER-SPANGLED HAMBURGH COCK.

I notice in your impression of the 8th inst., a letter from "J. W.," in which he complains of the Hamburgh cup at Leeds being awarded to my Silver-pencilled chickens, on the ground that the cockerel had odd sickle feathers—that is, one sickle was darker than the other, and that I felt "ashamed of the award." I cannot tell how he has come to the conclusion that I was ashamed, as, on the contrary, I feel proud of the achievement, and think this cockerel one of the best I ever exhibited.

Previous to the Show I had several cockerels brought in to choose from, and both myself and man came to the conclusion that he was the best. He caught cold at Leeds, and at Manchester I showed one of his brothers—well, he took the first prize; this pen was claimed. I then showed at Bristol another of the brothers, he also was first, and at Whitehaven I showed another brother, which likewise took the first prize, so that I think myself justified in considering him a good bird. I grant he has odd sickle feathers—that is, one feather silvered more than the other; but one feather being a good one, and the other better, I do not see that this should disqualify him. It is very common for Silver-spangled cocks to have one clear feather in the tail and the other splashed, but this does not disqualify a bird, although it would go against him, if another as good in all points, and superior in this, were opposing him. Now, allowing these odd sickles to be a defect (although the Judges may never have noticed it), I consider the bird in question to be the best shown at Leeds. This is my opinion, and "J. W.," of course, is at liberty to have his own. Still, if he will come over to Goitstock, if not too far, I will try to convince "J. W.," as the bird is now nearly well again, that he is one of the best birds out.—H. Beldon.

THE KENDAL EXHIBITION OF POULTRY AND PIGEONS.

So successful a Show as that which opened on the 17th inst., and closed on the 19th, has never before been held at Kendal. It took place this year in Duckett Mills, a newly-erected building exceedingly well adapted for the purpose, being a very extensive structure, of only a single storey, and well lighted throughout from the roof; in point of fact, nothing could be more desirable. The proprietor, Mr. Medcalf, generously placed it at the disposal of the Kendal Poultry Show Committee, and not only made a donation of three guineas to the funds, but at a considerable outlay made good all the means of access to the mill so perfectly, that even the most fastidious visitor could find nothing to complain of. The weather, as most of our readers might anticipate, was severe in the extreme. Many of the birds were consequently received in sad condition, but the Kendal Committee used every endeavour to revive them, and in many cases very successfully. The variety and liberality of the food provided, merits the highest eulogium. In spite of every effort, however, it was evident to visitors, that many pens of Pigeons and poultry were so far frostbitten during their railway transit to the Show, that it will take some considerable time before their recovery be completed.

There was a very grand display of *Game* fowls; in fact, it was the opinion of the Judges, that so many Black Reds, and of such excellence, had never before been shown at any one meeting. The *Hamburgh* classes were exceedingly interesting, every variety being represented well. Golden-spangled took the Hamburgh cup. Grey as well as White *Dorkings* were well shown; faulty legs and feet, however, seemed to be almost the order of the day, and this failing deprived many otherwise excellent pens of every chance of success. Both the *Brahmas* and *Cochins* mustered strongly, but many of the specimens seemed to be suffering acutely from the severity of the day. The *Bantams* proved a very excellent part of the Exhibition, a great variety of breeds being present. Duckwing Game were the winners of the Bantam cup.

Many of the *Turkeys* and *Ducks* shown were of unusual merit, and the cup for the best pen of Ducks of any kind, again, as at Whitehaven Show, was awarded to the extraordinary pen of Shell Ducks, claimed on that occasion, so that these excellent birds have, besides first prizes, taken two silver cups in a few days. They were much admired. Of Pintails, Widgeons, Carolina Ducks, and Mandarins, there was a good entry.

In *Pigeons*, few shows equal Kendal, as many first-rate birds are kept in the neighbourhood; and as liberal prizes were offered, the competition was severe. It is decidedly best, however, in the case of all Pigeons, to put the water outside the pens, instead of within the wires, as by the latter course the pens become wetted unnecessarily, and the plumage of the inmates soiled in proportion.

Game (Whites and Piles).—First and Cup, J. Fletcher, Stoneclough, near Manchester. Second, J. Brough, Carlisle. Third, H. Thompson, Maiden Hill, Penrith. Commended, W. Wainwright, Stetton-under-Fosse, near Rugby.

Game (Black-breasted and other Reds).—First and Third, J. Fletcher. Highly Commended, H. Thompson; J. H. Wilson, St. Bees. *Chickens.*—First, W. J. Cope, Barnsley. Second, J. Barrow, jun., Kendal. Third, E. Ackroyd, Bradford. Highly Commended, W. Boulton, Dalton in Furness; J. Hodgson, Whittington, Burton, Westmoreland.

Game (Any other variety).—First, J. Fletcher. Second, W. J. Cope. Third, H. Snowdon, Great Horton, Bradford. *Hen.*—First, T. Burgess, Burleydam, Whitchurch. Second, F. Pittis, jun., Newport, I.W. Third, T. Robinson, Ulverston. Highly Commended, T. Wilcock, Morley, Leeds; — Hodgson, Darlington; E. Akroyd. Commended, A. Fenton, Crimble Hall, Rochdale.

Hamburgh (Golden-pencilled).—First and Third, F. Pittis, jun. Second, A. K. Wood, Castle Donnington, near Derby. Highly Commended, R. McGregor, Perth; H. Beldon, Goitstock, Bingley.

Hamburgh (Silver-pencilled).—First, A. K. Wood. Second, W. M. Mann, Kendal. Third, H. Beldon. Highly Commended, J. Robinson, Vale House, near Garstang.

Hamburgh (Golden-spangled).—First and Cup, N. Marlow, Denton, Manchester. Second, S. & R. Ashton, Mottram, near Manchester. Third, J. Ogden, Hollinwood, near Manchester. Highly Commended, T. Burgess; A. K. Wood; J. Buckley, Taunton, near Ashton-under-Lyne; C. W. Brierley, Middleton, Manchester.

Hamburgh (Silver-spangled).—First, A. K. Wood. Second, J. Robinson. Third, H. Beldon. Highly Commended, J. Wright, Keighley; J. Robinson; A. K. Wood.

DORKINGS.—First, W. Copple, Eccleston, Preston. Second, J. Robinson. Third, W. Harvey, Sheffield. Highly Commended, Hon. Mrs. Howard, Kendal; T. Burgess; H. Reldon; W. Copple. Commended, Hon. Mrs. D. Pennant. *Chickens.*—First and Cup, D. Parsons, Cuerden, near Preston. Second, W. W. Ruttledge, Kendal. Third, J. Robinson. Commended, T. Kew, Burton, Westmorland; M. Brooksbank, Manchester.

COCHIN-CHINA (Cinnamon and Buff).—First, R. White, Sheffield. Second, J. Cattell, Birmingham. Third, A. Fenton. Highly Commended, Rev. F. Taylor, Keastwick, Kirkby-Lonsdale; W. Harvey; H. Mapplebeck, Woodfield, Moseley, Birmingham; H. Tomlinson, Birmingham. Commended, J. Poole, Ulverstone; Col. Stuart Wortley.

COCHIN-CHINA (Brown and Partridge-feathered).—First and Cup and Third, A. Fenton. Second, T. Stretch, Ormskirk. Highly Commended, E. Tudmao, Ash Grove, Whitchurch; Miss E. A. Aglionby, Hawkshead.

COCHIN-CHINA (White).—First, R. Smalley, Lancaster. Second, Rev. F. Taylor. Third, Rev. W. J Mellor, Colwick Rectory, near Nottingham. Highly Commended, R. Atkinson, Kirkby-Lonsdale; R. Smalley. Commended, G. Calvert, Darlington; W. F. Dickson, Gill Head, Whitehaven; W. Harvey.

SPANISH (Black).—First and Cup, T. B. Hartley, Heywood, near Manchester. Second, J. H. Wilson. Third, H. Beldon. Highly Commended, J. P. Harrison, Greenside, Kendal; J. Thresh, Bradford. *Chickens.*—First, E. Brown, Sheffield. Second, H. Beldon. Third, Hon. Miss D. Pennant, Penrhyn Castle, Bangor. Highly Commended, A. Fulton, Sedgwick, Milnthorpe; Hon. Miss D. Pennant; W. Harvey.

BRAHMA POOTRAS (Light).—First, H. M. Maynard, Holme Wood, Ryde, I.W. Second, T. J. Harrison, Singleton Park, Kendal. Third, W. H. Heelis, Hawkshead, Windermere.

BRAHMA POOTRAS (Dark).—First, R. W. Boyle, Bray, Co. Wicklow, Ireland. Second, J. Poole. Third, M. M. Brooksbank. Highly Commended, Miss E. A. Aglionby; J. K. Fowler, Aylesbury. Commended, A. Fulton.

FRENCH FOWLS (Houdan, La Flèche, or Crève Cœurs).—First, Col. Stuart Wortley, Grove End Road, London. Second, Rev. G. Hustler, Stillingfleet, Yorkshire. Third, W. A. G. James, Kirkby-Lonsdale.

ANY OTHER DISTINCT VARIETY NOT PREVIOUSLY MENTIONED, EXCEPT BANTAMS.—First, H. Beldon (Silver-spangled Polands). Second, Miss E. A. Whittaker, Belmount, Hawkshead (Cuckoo Dorkings). Third, Col. Stuart Wortley (Guelderland). Highly Commended, T. Wakefield, Golborne, Newton-le-Willows (Black Polands); J. Robinson (White Dorkings); Commended, E. H. Woodcock, Thornhill, Wigan (Silver-spangled Hamburghs and Black Polands); W. Harvey.

SELLING CLASS.—First, C. Garnett, Oxhenholme (Rouen Ducks). Second, J. Thompson, (Black Spanish). Third, R. Smalley (White Cochins). Highly Commended, R. Thompson (Duckwing Game); E. H. Woodcock (Black Polands); T. Pomfret, Preston (Dark Brahmas); T. R. Beetham, Sprint, near Kendal (Slate-coloured Muscovy); H. Thompson (Red Pile Game). Commended, G. H. Roberts, Penwortham, Preston; J. Barrow, jun. (Brown Red Game); E. H. Woodcock; J. Rawlinson, Hawkshead (Silver Grey Dorkings); H. Beldon (Silver-spangled Hamburgh).

GAME BANTAMS (Black-breasted and other Reds).—First, E. Joynson, Liscard, Cheshire. Second, F. Pittis, jun. Third, D. Parsons. Highly Commended, J. W. Morris, Rochdale; Master G. Crosland, Thorns Lane, near Wakefield. Commended, G. Smith, Staveley, near Chesterfield; W. Parker, Clay Cross, Derbyshire; W. H. Butcher, Lea Malt Kilns, Preston.

GAME BANTAMS (Any other variety).—First and Cup, F. Pittis, jun, (Duckwings). Second, Master G. Crosland. Third, Miss E. A. Aglionby. Highly Commended, Master G. Crosland; Master W. Sergeneson, Liverpool.

BANTAMS (Any other variety).—First, W. Cope. Second, H M. Maynard, Ryde, I.W. Third, M. Leno, Markyate Street, near Dunstable. Highly Commended, T. C. Harrison, Hull; J. W. Morris, Rochdale. Commended, J. R. Jessop, Hull; S. R. Ashton; H. Beldon; F. L. Roy, jun., Nenthorn, Kelso; Rev. F. Teale, Gazeley Vicarage, Newmarket.

SINGLE COCKS.

GAME.—First and Cup and Third, C. W. Brierley (Black Red). Second, J. Fletcher. Fourth, J. H. Wilson (Black Red). Highly Commended, J. Fletcher; C. P. Ackers, Bickershaw, near Wigton (Black Red); J. H. Wilson (Black Red). Commended, J. Cope; S. Dupe, Evercreech, Bath; J. Hodgson (Black Red); D. Tait, Hawkshead (Black Red). *Cockerel.*—First, H. Snowdon. Second, F. Sales, Crowle, near Bawtry. Third, J. Wood, Wigan. Fourth, F. A. Astbury, Manchester. Highly Commended, J. Pennington, Birkenhead Park; W. J. Cope.

DORKING.—First, R. D. Holt, Orrest Head, Windermere. Second, O. E. Cresswell, Hounslow. Commended, D. Steel, Windermere; J. Robinson.

GAME BANTAM.—First and Cup and Second, C. W. Brierley. Third, R. Gerrard, Chowbent, Manchester. Highly Commended, Rev. W. J. Mellor. Commended, J. W. Morris, Rochdale; T. Eastham, Preston.

BEST GAME COCKEREL AND PULLET (Any variety).—First and Cup and Third, M. Graham, Kendal. Second, J. Gelderd, Kendal. Highly Commended, R. Woof, Old Hutton. Commended, R. Woof; J. Barrow.

BEST PEN OF HAMBURGHS (Any variety).—First and Cup, T. Suart. Second, S. C. Noble, Kendal (Silver-spangled). Third, H. Arnold (Pencilled). Highly Commended, G. Walker (Silver-spangled). Commended, H. Arnold (Pencilled); S. C. Noble (Silver-spangled).

BEST PEN OF SPANISH (Black).—First, J. Harrison, Cowan Head, Kendal. Second, T. Simpson. Third, J. Goth, Woodside, New Hutton. Highly Commended, J. P. Harrison. Commended, J. Watson

BEST DRAKE AND DUCK (Any breed).—First, W. Willison, Underbarrow. Second, W. Taylor, Kendal. Third, T. J. Harrison.

BEST PEN OF TURKEYS.—First, T. J. Harrison. Second, T. Airey, Crooklands. Third, Mrs. T. N. Clark, Fell End, Witherslack. Highly Commended, R. Noble, Kendal; T. J. Harrison.

DUCKS (White Aylesbury).—First and Third, J. K. Fowler. Second, E. Leech. Commended, J. Robinson.

DUCKS (Rouen).—First, J. Robinson. Second, W. Copple. Third, J. J. Waller, Kendal. Highly Commended, J. Redhead, Kendal. Commended, C. Garnett; T. Burgess.

DUCKS (Any other variety).—First and Cup, C. W. Brierley (Shell Ducks). Second, T. C. Harrison (Mandarin). Third, J. Jennison, Belle Vue, Manchester (Carolinas). Highly Commended, A. Suart, Staveley, near Kendal (Penguin Ducks); F. Pittis, jun. (Buenos Ayrean); A. Fenton (Grey Calls and Buenos Ayrean); J. Jennison (Pintails and Widgeons). Commended, C. W. Wilson, High Park, Kendal (Wild Ducks); H. Beldon (Grey Call).

PIGEONS.

CARRIERS.—First, H. M. Maynard. Second, W. Jackson, Bolton-le-sands. Highly Commended, J. Hawley, Bingley; H. Yardley, Birmingham.

TUMBLERS (Almond).—First, F. Key, Beverley. Second, H. Yardley. Highly Commended, J. Thackray, York; J. Fielding, jun., Rochdale.

TUMBLERS (Any variety).—First, J. Hawley. Second, J. Fielding, jun. Highly Commended, J. Thackray.

OWLS.—First and Second, J. Fielding, jun. Very Highly Commended, J. Thackray. Highly Commended, J. Thompson.

POWTERS AND CROPPERS.—First, W. Harvey. Second, J. Thackray Highly Commended, J. Thackray; H. Yardley.

BARBS.—First, R. Thompson. Second, J. Cragg, Kendal. Highly Commended, J. Fielding, jun.; G. Sturgess, Leicester. Commended, H. Yardley; R. G. Hadwin.

FANTAILS.—First, R. Dodge, Sheffield. Second, J. Thackray. Highly Commended, H. M. Maynard; H. Yardley; F. Waitt. Commended, J. Thackray; J. R. Jessop; H. Arnold, Aikrigg End, Kendal; H. Yardley.

TURBITS.—First, R. Thompson. Second, W. Harvey. Commended, F. Waitt.

TRUMPETERS.—First, R. Dodge. Second, J. J. Wilson, Darlington. Commended, J. Thackray; Rev. W. J. Mellor; G. Sturgess.

JACOBINS.—First and Second, R. Thompson. Highly Commended, J. Thompson; G. Sturgess. Commended, H. Yardley; F. Key; F. Waitt.

ANY OTHER VARIETY.—First, F. Waitt. Second, J. Wainwright. Very Highly Commended, F. Pittis, jun. Highly Commended, J. Thackray; J. W. Thompson, Hull; W. Jackson, Bolton-le-Sands; H. M. Maynard. Commended, J. Thackray; Bowman & Fearon, Whitehaven.

SELLING CLASS (Any variety).—First and Second, W. Harvey (Hyacinths and Priests). Highly Commended, F. Winn, Ullswater, Penrith; J. Walker, Newark; R. Thompson; R. G. Hadwin, Collin Croft, Kendal; R. Smalley, Lancaster; H. M. Maynard; J. Hawley; H. Beldon; J. Thompson; H. Yardley; E. Brown, Sheffield. Commended, W. R. Park, Abbotsmeadow, Melrose; R. Smalley; W. Jackson; C. W. Wilson; J. Thompson; F. Waitt.

Messrs. Edward Hewitt, of Sparkbrook, Birmingham, and Richard Teebay, of Fullwood, near Preston, were the Arbitrators.

THE PHILOPERISTERON SOCIETY'S SHOW.

THE annual Exhibition of Pigeons held in the great hall of the Freemason's Tavern, Great Queen Street, Lincoln's Inn, on the 15th inst., was, as usual, very interesting, and attracted large numbers of Pigeon-fanciers. Carriers were numerously represented by collections of great excellence from Messrs. Date, Square, Else, and Everett; and the Duns, Blacks, and Whites from Messrs. Crossley, Hedley, and Carroll were much admired, as were the beautiful Tumblers exhibited by Mr. Esquilant. A collection of thirty Powters, shown by Mr. Volekman, constituted of themselves a great attraction. The Almonds from Mr. Lucy and Mr. Merck, and the Fantails, Jacobins, Turbits, Magpies, Helmets, and Nuns from Mr. Wicking were of great excellence, and so were the specimens of Almond Baldheads contributed by Mr. Morris. Of Barbs some beautiful Blacks, Reds, and Yellows were exhibited by Mr. Hedley; and Dragons of high excellence were contributed by Mr. Jones Percival and Mr. Crossley, the latter exhibiting the pair of Blue Dragons which took the first prize at Birmingham. Fine specimens of the above and other varieties were contributed by Mr. Thackray, Mr. Betty, and others.

A DAY IN THE RIFLE DRILL HALL, BRISTOL.

WHEN I drew up my blind on Wednesday morning, January 2nd, and saw how the earth was covered with snow, and the atmosphere was filled with it, and how the light had to struggle through clouds as full of snow as a filled sponge with water, I said to myself, "I am very sorry for my Bristol friends, for I fear their Show will be ruined." All Wednesday the weather was bad, traffic was impeded, and none stirred abroad, unless they were driven from home and shelter by dire necessity, save a few snowball-loving boys, and they, too, were obeying the law of necessity, for youth and health tingling to the fingers' tips prompt mirth and mischief.

Thursday morning, however, broke fine and clear, no more snow had fallen, and a frost on snow makes it dry and crisp, altogether a different and less-dreaded material to snow in its new-fallen, light, wet, and boot-soaking condition. This cheered me, for I saw more hope of people getting out to a poultry show. Forth I went, enlivened by the air and the bright day.

As I travelled on I could but notice the transforming power of snow, how it so masks Nature that one loses oneself even in tolerably well-known roads. The seasons, indeed, alter a scene, but snow makes it altogether a new scene—it thoroughly disguises the face of dame Nature; earth white and all alike, trees standing up black and frowning. Bristol, not too clean, but still a most interesting city, reached at last, and its narrow streets threaded, its docks passed, and draw-bridge crossed.

College Green, to my left, alive with sliders, and beyond it the cathedral, now restored, but still how inferior to the church of St. Mary Redcliffe. What a city rich in architecture, to possess both a cathedral and, perhaps, the very finest parish church in England! I think of Chatterton, Southey, Coleridge, and, greater than all, Bishop Butler, the author of the wonderful "Analogy."

Pressing on I am at the foot of Park Street, a fearful hill always, but now doubly fearful with the frost. I see before me carts locked together; horses, whose careless owners had not caused their shoes to be roughed, putting out all their strength to drag forward heavy vehicles, but strength only ending in slipping and no advance; foot-passengers here and there falling, if ladies, to the infinite damage of their chignons. Soon, but not very soon, I am at the top of this hilly, slippery street, and alight in front of a new building to my right, and, after walking down a corridor, I am in the Rifle Drill Hall.

First, I would remark, that the situation of this hall is admirably fitted for a Bristol and Clifton show, as it stands midway between the two places. It is convenient both for Bristol citizens and Clifton residents. It is no long walk for the Bristol man of business or fowl-loving artisan, and the daintiest Clifton boot can reach the hall unsoiled by city mud. So much for its situation; as much may be said for its interior capabilities. It is large, nearly square, the roof supported by light iron arches, the lighting admirable, and, gas being burnt, the temperature was most agreeable to man and bird.

The arrangements of the Show were excellent, and must have cost the Committee, all amateurs, much thought and work. I walked round and round trying to see where I could suggest improvements; but I am unable to suggest one, and as to blots there were none to hit. The pens were good and large, the space between the rows was ample, more room being given than is usual, neither were the pens so high as to preclude a view of the hall, or of one's friends in other parts of the building. Not unfrequently the pens are so high that I feel as if walking between two fen banks. Then across the two ends were the Bantam pens; this was a very good arrangement. These little fowls look best when separated from the larger birds, and as one came down each row, there, full before one, was the whole range of the fairies; this was a very pretty feature. Along the side wall were benches with backs, and between each two benches a large evergreen plant or tree. Then above floated numerous flags and many twinkling points of flame, which raised the temperature so pleasantly. In one corner was a refreshment stall, where the viands were not dear and *were* good, and the proprietor need not read "The Boy at Mugby" in "Mugby Junction." Standing at the refreshment counter one saw the hall to full advantage, and though fully remembering other shows and my pleasure at them, yet I must dub this as the very prettiest and best-arranged winter show at which I ever was present. We had light, warmth, good taste, and nearly eight hundred pens of poultry. Owing to the pleasant temperature the birds did not mope in corners with hanging heads and ruffled plumage, but showed to advantage.

It will be needless for me to repeat the prize list, rather I will mention any features of the Show which seem to me to demand particular notice. First, a word about the Spanish. I was prepared to expect much at Bristol in this class, knowing who resided in and near; but the excellence of the birds surprised me. The chickens, especially, were deserving of an emphatic "Most excellent;" they belonged to Messrs. Parsley, Roué, Lane, and Jones.

Lady Holmesdale carried off, to add to her many cups, one, I think, better than any her ladyship previously possessed —viz., the cup of the Show; but it was not won easily; other pens were nearly if not altogether, to some judgments, quite equal to hers. The first-prize White Cochins were again most admirable; I could scarcely leave the pen. The Partridge Cochins were again extremely good; next to the Spanish I preferred this class. The third-prize pen of Light Brahmas bore a ticket stating "These birds have been purchased by Her Majesty." The Game were of varied goodness, some even not dubbed. But, well! they paid their entrance money; but why will people send birds to be laughed at? I was able to feel Mr. Fletcher's first-prize hen as she passed close to my hand, and the hardness of feather was wonderful.

It was really quite pleasant to see so many pens of Polish, birds always attractive at a show; may I beg many a breeder to have at least one sitting of eggs this spring?

Among the more recently imported varieties I would decidedly state that the Houdan is much the handsomest breed, and worthy of becoming more generally known; by the way, it might be well to print the names of these new kinds in the catalogue.

The Bantams, seen so well at this Show, were also well worth seeing. The first-prize Duckwings were admirable; and Mr. Cambridge's Blacks were first, and the cock, perhaps, the very best I ever saw. It pleased me to see the old-fashioned Speckled Booted. Horace Walpole frequently mentions, "I first fed my Bantams." He was an early riser, and I apprehend his were these Booted Speckled—the best known in the last century. Let me press upon readers having but a small yard or garden to go in this year for Bantams; nothing is a prettier pet.

Ducks, Geese, and Turkeys—happy Geese and Turkeys to have survived Christmas—abounded. The Brown Call Ducks pleased me extremely, perhaps the prettiest of the smaller Ducks, though apt, if allowed to fly, to be shot by mistake for wild Ducks. The little Blacks are very nice for a small piece of water, and may be kept like Bantams where larger birds are unsuitable.

I spent the chief part of a too-brief winter's day in the Rifle Hall, and though I have no blot to hit nor improvement in arrangement to point out, yet I would in conclusion remark, that the first few days in the New Year are not good days for exhibitions; people's heads are full of visiting, Christmas is scarcely gone, indeed, I found that neither lectures nor penny readings were well attended so soon in the year; Paterfamilias is also grumpy, owing to those bills, always larger than he expected, and instead of, as at other times, fobbing out five shillings with a smile for all his family to go to the poultry show, he, with the youngest in his hand, now says, "No, girls, we must economise; think of what those bonnets of yours cost me." This is all I can suggest, as the Secretary told me there were to be Pigeons next year—Pigeons that cost so little for carriage, that a great number may always be relied upon as sure to be sent. Trusting that the Bristol Show may be an annual one, and ever be well attended, I heartily thank the Committee for the pleasure they have given me.—Wiltshire Rector.

AMERICAN BEE-KEEPERS' INSTITUTE.

A Bee-keepers' Institute has been established on Kelly's Island in the state of Ohio, where an association which claims to be "composed of the best apiculturists" proposes for "a small compensation" to educate its patrons in the science and art of bee culture. Advantage has also been taken of its position to introduce the Italian bee into Kelly's Island, where it is stated to be separated by a distance of twelve miles from any native bees. Queens of this variety are advertised for sale at eight dollars (about £1 13*s*.) each, with a reduction on taking a quantity.

SHIFTING STOCK HIVES.

One of the most important principles to be attended to in practical bee-keeping is, Never to shift stock hives, but to allow them to remain, as De Gelieu says, "fixed to the spot as the ancient oaks." Many people imagine they may be safely moved a few miles in winter, but in my opinion, this is a very improper time to change their situation. However gently handled, a certain amount of disturbance necessarily takes place, and then the bees, which were previously inactive, begin to consume food, which will inevitably be attended with evil if the weather be such as to confine them to their habitations for any length of time. Of this I have had indubitable evidence on several occasions.

Two years ago, on a comparatively mild day in January, I had a hive in excellent condition carefully conveyed on a pole by two men to the distance of a mile, but the commotion induced by the carriage made itself felt during the remainder of the season. On account of the inclement weather that followed, the bees were unable to leave their hive for several weeks, and the frequency with which they approached the entrance without daring to venture out, showed the deep distress they were in. Numbers fell down on the floor-board and died; those that did go out never returned, and in a short period every bee would have perished had not an exceptionally fine day seasonably arrived, which permitted an airing to be taken. Other hives which had not been interfered with did not appear to suffer in the least during the period of confinement referred to.

On another occasion, peculiar circumstances led me to rouse a hive into complete activity about the beginning of December,

It was a remarkably strong stock, and appeared capable of standing the severest weather. If egress had been possible, I have no doubt it would have done well, but a period of chilly ungenial weather set in, the temperature gradually fell, and very few of the bees which came out of the hive were able to return to it. About the middle of February following the thermometer indicated 18° of frost, and as the bees by that time were filled to repletion, they could no longer take in more food so as to enable them to keep up the requisite degree of warmth in their hive. The consequence was the death, in one night, of nearly five thousand bees still attached to each other in a cluster.

Such are the evils which I have observed to follow on an unseasonable interference with stocks; but even when a hive is removed in the winter season to a strange place, and in the gentlest possible manner, vast numbers of the population perish if a fine day do not immediately follow, so as to tempt the inmates to come out in a body; for if they leave the hive singly or by twos and threes, they generally do so without taking much notice of the aperture to their houses, and as they fly about for some time without being able to find it, they soon become benumbed, and so fall down and die. Not one in a hundred when the temperature is low can make its way back to its home after removal to a new locality; for the place is strange, a considerable time has to elapse ere a sufficient survey of it can be taken, and there are very few days in the winter months when bees can with safety linger much more than a minute or two out of doors. It is different when the day subsequent to removal is genial and fine. They then come out in such numbers as to make an inexperienced person believe they are going to swarm, and as they crowd around the entrance, those on the wing examining the new situation are at once directed to the home which they might not otherwise have found.

With these facts many bee-keepers must be well acquainted, and it is only for the benefit of novices I state them. I would, therefore, tender this advice, Never to remove stocks to either a short or a long distance during the months of December, January, and February, or if you do, let it be early in the forenoon, and on a day when, about noon, in their new situation the bees may with safety be allowed to go abroad.—R. S.

OUR LETTER BOX.

Hen's Abdomen Swollen (*Tycho*).—If the hen you mention first be a Spanish hen, it is the beginning of an incurable malady; in all cases such attacks are incurable, but very often they do not interfere with the usefulness of the bird. We cannot guess at the cause of illness in the two pullets, but eating snow sometimes causes strange maladies.

Promoting Laying (*Novice*).—Very few fowls lay in this weather. Cooked meat chopped fine, bread soaked in ale, and ground oats mixed with milk, tallow chandlers' greaves soaked in boiling water, a little hempseed, are all stimulating food, and tend to make fowls lay, but they injure the birds.

Game Fowls with Different-coloured Legs (*Scot*).—If the pen included none but the finest and best birds that were ever seen or bred it could not compete, as the difference in the colour of the legs is a positive disqualification. It used to occur at the shows in this country formerly, but of late we have never seen it.

Height of Inclosure (*Suffolk Subscriber*).—A fence 5 feet high will keep almost any fowls within bounds, unless they are tempted by something on the other side which their confinement does not afford; but even then they will seldom attempt it, more especially if the fence is made to slope inwards.

Houdans Confined (*Idem*).—Houdans do as well in confinement as at liberty, and a four-feet fence will keep them in.

Pheasants Confined (*Idem*).—Common Pheasants bear confinement well, and can be profitably kept. No license is required for selling their produce.

Dubbing Game Bantam Cocks (*Gallus*).—They, as well as Game cocks, may be dubbed at from five to seven months old. The best way is to use a pair of curved scissors, and to cut from the back of the skull to the nostril, keeping so close as to leave no comb whatever, but taking care not to expose the skull. Afterwards remove the gills and deaf ears with the same instrument. Other birds than we have mentioned may of course be dubbed, but not younger ones, as, if the operation is performed too early, the combs grow after it, and it again becomes necessary.

Detecting Fertile Eggs (*C. S.*).—We can tell you of no way of testing the fertility of eggs till they have been sat upon for a few days. Take an egg that has been sat upon five days, and, choosing the strongest light you can, sunlight if possible, place yourself in a dark house, and open a chink of the door to admit a small strong ray. Then hold the egg between the thumb and finger of the left hand, while with the right you form a telescope, as it were, and fixing it close to the eye at one end, if you press the egg against the other, no light will be admitted save through the egg, and if it be fertile you will after five days' incubation distinctly see the streak of blood in the yolk. This is the first formation of the chicken. If the egg is quite clear there is no life in it; at a later period the eggs show by motion when they are put in warm water.

Fowls with Disordered Throats (*D. G.*).—To your fowls which make a hiccoughing noise give some bread and strong beer. They are suffering from cold.

Number of Eggs a Hen Lays (*T.*).—The number of eggs laid by a hen is not affected by the cock, but, as a whole, the hens do better, even if there be but one cock to twenty hens. We do not know the price of feathers.

Geese with Long-projecting Feathers (*E. N.*).—Your Geese are either Sebastopol or crossed with that breed. The pure bird is very beautiful, generally white and covered with long curling feathers, but they are not very heavy. That is our reason for thinking yours are not pure.

Mixture of White and Buff Cochin-Chinas (*D. M., Glasgow*).—We are unable to say what colour the produce of the cross would be, but it has always been said the Black Cochins were produced in that way. It is certain they could not be continued on account of their eccentricities in the way of colour.

Poultry for a Small Yard (*M. A. Healey*).—Any of the dark varieties of Cochin-Chinas or Brahma Pootras will suit you.

Handling Poultry at Sales (*W. H. M.*).—There is no rule that we know either sanctioning or forbidding the practice. The safest way would be not to have a bird taken out or put into a basket, except by an attendant appointed by the auctioneer.

Dorkings (*Nemo*).—If we were about keeping Dorkings we should purchase pullets and a cock, either at one of the exhibitions or at a sale at Mr. Stevens's, King Street, Covent Garden, taking care not to have them a brother and sisters.

Good Intention.—If "*Inquirer*" will enclose to us a stamped envelope with his direction we will send him the address of a lady who will meet his wishes as far as her stock of the various fowls will allow.

Fern Cloths (*J. J. S.*).—We have seen ferns printed in black on a white ground, but never white on a black ground. It must be effected in the dying.

Crève Cœurs at Shoreham Show.—In the prize list of the Shoreham Poultry Show you gave me credit for taking the second prize for Game Bantams, which is a mistake, but I had the second prize for Crève Cœurs. —J. C. Phair.

Flight Feathers of an Owl Pigeon (*Elms*).—The flight feathers should not be of the same colour as the wing bars, but of the same colour as the body of the Pigeon—thus: in Blue Owls blue, in Silver Owls silver.

Food for Game Fowls (*Bosch*).—Feeding on Peas is said to be best for hardening the flesh and feather. Barley is best for cold winter weather, as being the warmest food. For warm summer weather red wheat, oats, rye, buckwheat, or brank, is best; the latter is also good for winter feeding. I feed my Game fowls on barley in winter, and on barley and red wheat in summer. The hardness of feather and flesh, or what is termed "good condition," of course, greatly depends upon the strain or breed of birds kept. No good feeding can make soft birds hard, and good condition also greatly depends upon a good healthy country walk and great cleanliness, as bad walks often spoil good birds. My articles in this Journal begin with the Number of September 18th, 1866; pages 321, 415, and 436, give other information such as is required by "*Bosch*."—"Newmarket."

Poultry Keeping (*M. I. E.*).—To answer all your queries would fill a column of our Journal. If you enclose seven postage stamps with your address, and order "The Poultry Book," it will be sent to you free by post. It contains all the information you ask for, and much more that will be useful to you.

Bird Dealers (*I. S. R. D.*).—In answer to your application we give the following:—Mr. Hawkins, Bear Street, Leicester Square; Mr. Judd, 25, Newington Butts; Mr. Fraser, The Green, Knightsbridge; Mr. Isaacs, 32, Prince's Street, Leicester Square; Mr. Jamrach, 180, St. George Street, E.; Mr. Rice, 156, St. George Street, E.

Maggots in Combs—Breeding in Supers—Storing Combs (*E. B.*).—You should go over the combs carefully, and pick out and destroy every maggot, or the combs may be entirely destroyed before the time comes for making use of them. You run no risk in trying to utilise these combs after destroying the worms, for if they are too far gone to be available the bees will soon make an end of them. Queens are not so prone to breed in supers when the communication with the stock hive is at the sides only. It is said that queens may be entirely excluded from supers by the communication being restricted to narrow slits one-fifth of an inch wide. We should be glad if any of our readers who have tried this plan would communicate the results of their experience. We do not imagine that any one sells wire suited for drone traps, but believe you must get it made purposely for you. Empty combs after having been carefully inspected, to make sure that they are free from wax moth, should be wrapped in paper and put away in a box or drawer in a perfectly dry place.

Packing Eggs for Travelling (*Spangled Hamburgh*).—We cannot reply better than by quoting the following from "The Poultry-Keeper's Manual," published at our office:—"We know of thirteen eggs which, after journeying 360 miles (from Winchester to Kendal), produced nine chickens. They were in a strong box, 2 inches of bran at the bottom, then an inch layer of oats, on this the eggs were laid on their sides, covered an inch deep with oats, and then 2 inches deep of bran. A gentleman of much experience wrote as follows to us on this subject:—'As an experiment to test my mode of packing eggs, I sent five eggs more than 170 miles by railway; they were absent three days, and twice travelled through London in the railway van. On their return they were placed with some other eggs under a hen, and four out of the five eggs were duly hatched. These eggs were carefully packed, and the lid of the box screwed down. The only objection to oats, as a packing material, is, that sometimes, but very rarely, an egg may be pierced with the sharp end of an oat; I have only known, however, one or two instances of such an accident. The plan I now adopt in packing eggs is to wrap each egg in several folds of newspaper, and then place a thick layer of cotton-wool and straw cut to the length of the box, both under and over the eggs, filling up every interstice with pledgets of cotton-wool. This plan prevents any chance of the eggs being broken, and preserves their vitality as well as is done by the oats. There is one thing I invariably do, and I think ought to be done by every one who sells eggs for sittings, and that is to write on each egg, legibly with a pencil, the date on which it was laid. Egg-boxes should invariably have their lids screwed down. I have constantly received boxes of valuable eggs, of which not one has hatched, and, I believe, solely in consequence of the lids being nailed down, the jar of the hammer destroying the vitality of the egg. No eggs should be packed in sawdust, nor should eggs more than ten days old be sent to any distance.'"

WEEKLY CALENDAR.

Day of Month	Day of Week.	JAN. 31—FEB. 6, 1867.	Average Temperature near London.			Rain in last 39 years.	Sun Rises.	Sun Sets.	Moon Rises.	Moon Sets.	Moon's Age.	Clock before Sun.	Day of Year.
			Day.	Night.	Mean.	Days.	m. h.	m. h.	m. h.	m. h.	Days.	m. s.

5	Tu	Acacia Drummondi.	45.4	33.5	39.4	18	35 7	54 4	38 7	2 6	1	14 16	36
6	W	Azaleas.	46.1	32.5	39.3	20	34 7	55 4	7 8	10 7	2	14 20	37

From observations taken near London during the last forty years, the average day temperature of the week is 44.7°; and its night temperature 31.8°. The greatest heat was 57°, on the 1st, 1852; and 3rd, 1850; and the lowest cold 8°, on the 31st, 1857. The greatest fall of rain was 0.75 inch. N.B.—The Calendar contains the names of plants flowering in the greenhouse.

NEW AND BEAUTIFUL PLANTS,

RECENTLY INTRODUCED.

BEAUTIFUL as many of the stove plants are that have been distributed to the public by Messrs. Veitch and Sons during the last year or two, there is none more effective and useful than

Begonia Pearcei.—This very beautiful species is botanically allied to B. cinnabarina, and it was introduced from La Paz by Mr. Pearce. It possesses the double quality of having both beautiful leaves and large showy flowers; the plant has also a very desirable habit. The foliage is very pretty, the upper surface being of a dark velvety green, traversed by pale straw-coloured veins, and the under side of a dull red colour. The flowers are large, bright yellow, and borne on slender stalks in clusters of two or three. Sometimes only one flower is borne on a peduncle, when this is the case the flower is very much larger; some which I have seen were as large as a five-shilling piece.

I have no doubt that this beautiful Begonia may be had in bloom all the year round, if care be taken in propagating and resting the plants at the proper time; and, as the flower-trusses are produced in large numbers and the colour of the flowers is rich, it will be found invaluable both for summer and winter decoration. The plant thrives well in a mixture of peat, leaf soil, loam, and silver sand, and is easily propagated by cuttings or leaves.

To have it in bloom throughout the year it will be necessary to propagate plants every two months. The young plants should be grown in a brisk temperature, and as near the glass as possible. As soon as they have become well established in their pots, a little weak manure water will assist them very much if given once or twice a-week: a well-grown plant in a 48-sized pot will afford a constant succession of bloom for three months. After the plants have done flowering water should be withheld for a period of three or four weeks, when they may be gradually started into growth again, so that, after two or three dozen plants have been propagated, there may be a constant succession of beautiful flowering specimens.

For drawing-room decoration I know of no more useful plant, as the flowers do not fade very soon, and if small examples are used for this purpose they will be found invaluable. I have great pleasure in recommending this beautiful plant for all purposes.

Primula cortusoides amœna is another most welcome addition to our stock of plants for spring and early summer decoration. This plant appears to be nearly if not quite hardy, the flowers are produced on slender stems, and form large umbels several inches in diameter, which are borne well above the foliage; the colour of the flower is a rich rosy purple. This is one of the beautiful plants introduced by Mr. J. G. Veitch from Japan. It is propagated by dividing the roots. A good, yellow, sandy loam, with a little leaf soil, appears to suit it well. The plants must be grown in a cool frame or pit, and be fully exposed for two or three months after the flowering season, and the pots should be plunged in some material to keep the roots cool and moist during the summer.

I have no doubt this beautiful Primula will soon be followed by others equally good in various shades of colour. It is to be hoped that the plant will produce seed as freely as the original species; if so, there will be a wide field for its improvement, and a few years will, doubtless, bring us as many and varied forms of this valuable species as there now exist of the rapidly increasing section of the Chinese Primulas. I have not yet seen the seed of this beautiful Primula advertised, but it is to be hoped Messrs. Veitch will soon be able to distribute it to the public.

Urceolina aurea is a beautiful, very graceful Amaryllidaceous plant, requiring the same treatment as Eucharis amazonica. It has broadly ovate leaves like the above, and a tall scape supporting an umbel of gracefully drooping bright yellow flowers tipped with green. The plant is propagated by offsets.

Manettia micans.—A valuable stove climber, with rich, glossy, dark green foliage, and producing its bright reddish orange-coloured flowers very profusely during the whole winter. The plant is a vigorous grower, and valuable on account of its quick growth for covering pillars, &c.

Bignonia argyreo-violascens is a pretty variegated stove climber, with shaded purple and white leaves. The young foliage is beautifully coloured with various shades of lilac and purple; it is very distinct and striking, and forms an admirable contrast with the green and glossy leaves of Manettia micans.—J. Wills.

(To be continued.)

DANGER FROM ACCUMULATED HEAT.

The recent fire in the Crystal Palace, which all must regret, reminds me of a subject which has long occupied my mind, and that is accumulated heat. Almost every year we hear of some fine building in danger or destroyed by fire, and the same reason given—namely, overheated flues. Of course, if this is the cause in all cases, the persons having the charge of the fires are to blame; and one may imagine with what feelings they will be regarded by those who have lost their home, and many of home's treasures. I do not believe, however, those who have charge of such heating apparatus are in all cases or generally to blame.

If a hot flue be surrounded in such a way that the heat cannot readily escape, and it be kept constantly hot, this heat must accumulate. There is a general idea that if a flue does not touch wood or other inflammable substance a fire cannot take place:—no idea can be more erroneous. A hot flue is constantly receiving heat; if surrounded by non-conducting but inflammable substances the heat must accumulate, and may reach the point at which ignition takes place. Besides, it is well known that wood constantly subjected to heat becomes more and more inflammable.

I have heard that a large warehouse in Manchester was very nearly being burnt down from a quantity of cotton being laid against the wall of a room, on the other side of which was a fire kept burning night and day. My own house was in danger of being burnt, and, in fact, was on fire from this cause—accumulated heat.

In consequence of the sickness of one of my children a good fire was kept up in a bedroom night and day for some weeks; the fireplace was a rather low one, and the hearthstone, a large and thick stone, was laid upon the beams which carried the floor; of course the bottom side of these beams was covered by the ceiling of the room below. No fire touched the hearthstone, the bottom of the fire was a foot above it, yet, on a burning smell being perceived, search was made, and the wood was found on fire, and only air was wanted to produce flame.

My attention was first directed to this subject more than twenty years since in the following manner:—Having a flue running through a greenhouse I thought to make a hotbed for striking cuttings over it; so I built a wall in front of it some 18 inches or 2 feet higher than the flue, and laid some pieces of wood across, which were covered with slates, on which was placed a bed of leaves. I had as nice a hotbed as could be desired, and all went on well till one morning I found the place on fire, and all the plants killed. The thick bed of leaves prevented the escape of heat in anything like the proportion in which it was given out by the hot flue: hence the accident.

In warming an old house by flues it is almost impossible for the architect to know the position of every piece of wood; and even in a new house hot water would be much safer. There is an old saying, that experience is of no value till it is paid for, but a fire in one's dwelling-house is too great a price to pay for knowledge, so I hope these hints will be useful.—J. R. Pearson, *Chilwell.*

WHAT IS A GOOD CROP OF STRAWBERRIES?

May I suggest an answer to the above question as a very important item in the consideration of the particular aspect of Strawberry culture, discussed of late in the pages of the Journal? Could "J. T.," or others, state definitely that in such a year, from so many square yards of land, there were gathered so many pounds weight of Wonderful, and from some other number of square yards in the same field, so many pounds of Frogmore Late Pine, the question of the relative cropping of these two varieties would be reduced to the best of all tests—an arithmetical calculation. Given a certain soil, season, situation, and mode of planting we should have determined positively for us which of these two sorts excelled the other in cropping, and to what extent. Presuming the time and course of ripening of the two were identical, the comparative value of, perhaps, a better crop in one to a superior flavour in the other, would remain to be estimated, and this done, we should have ascertained a fact to be remembered so long as Frogmore Late Pine or Wonderful was worthy of a place in our catalogues. Had your correspondent Mr. John May, March 20th, 1866, only told us the distance between the rows, and between the plants in the rows, from which he gathered 96 lbs. of fruit, how valuable it would have been to have had such a standard to test our results! If Mr. May's 144 plants produce 96 lbs. and mine only 45 lbs., I at once understand that my system of Strawberry culture wants reforming; yet here we are, hundreds of fragarians, congratulating ourselves and neighbours upon magnificent crops, while one and all of us are positively ignorant of what really constitutes a crop worth growing!

Fruit-farmers who have kept their books well could furnish us with much in this direction, both of interest and value. Till they do so, let some of us, who have time to spare, devote an hour or two in the coming season to weighing, as accurately as the blackbirds will allow us, the crop produced on any convenient plot completely under our own supervision. As an estimate of what even in ordinary culture may be expected, I may remark that a crop of 10,800 lbs. per acre, or nearly 2¼ lbs. per square yard, is certified to have been produced in the State of Maine, U.S. I believe it will be found that our best English growers far exceed this; how far, it is worth a little trouble to ascertain.

May I suggest, without seeming over-critical, that in the question of produce generally there is a degree of looseness of statement which our good friends the agriculturists have long since ceased to tolerate? When the cropping-merits of a new Potato or other vegetable are boasted of, let its admirer, when speaking of its wonderful crop, tell us also something of the weight and scales he measured it by. I do not mean that anyone wilfully mis-states, but when one of those earliest of all Peas is fit for the table on some early day in May, it would add to our interest to know the length of the row, the number of the pods, and the gross weight of the whole—say even the number of Peas.

Seriously, let us apply this matter of weight and scales to a question which was lately adverted to in your columns. If Mona's Pride be ten days earlier than the Ashleaf, the sooner we all have it in our gardens the better. I saw it hinted the other day that the Ashleaf was considerably the earlier of the two. Now, who is right? Every one speaks out tolerably strongly, but on what basis? What of the scales and weights? Let us settle this before another season passes over. Given, fifty sets of each sort of like average size, planted on the same day, let ten plants of each be lifted on the 15th of May, their produce weighed, and all tubers above 2 ozs. counted. Repeat this every five days, and by the middle of June each grower, for himself at least, may determine whether, in the event of the spring of 1867 being an average one, he should or should not continue to grow the variety in question; and something like this was just what the introducer of Mona's Pride was morally bound to do for his constituents, and to publish the results, before presuming (if he did presume), to offer it at 5*s.* per peck.—S. E. T.

CONFLICTING HORTICULTURAL EXHIBITIONS.

I am glad to see that Mr. D. Thomson has directed attention to the unfortunate circumstance that the days selected by the Royal Horticultural Society for holding their large show next summer are the same that had previously been fixed upon for holding the great National Show at Manchester.

It has long been known that such a show would be held at Manchester in the summer of 1867; it has been noticed by the press, both editorially and by correspondents, and it is impossible to believe that any of the great Societies could be ignorant of the fact of the show itself, or of the dates on which it was to be held.

As the Royal Horticultural Society, in particular, have for their object the advancement of horticulture, it is a pity that they should so arrange their programme that the principal show in London should come in direct collision with what is likely to be the most extensive one held in the provinces. Exhibitors may be anxious to contribute to the Manchester National Show, and at the same time be desirous to let their plants, &c., be seen at South Kensington as usual. This might have been done if the Royal Horticultural Society had fixed upon a different date from that already occupied.

Many visitors will be desirous of witnessing the National Show as a first attempt at a long-continued exhibition in the provinces, and at the same time they will not like to miss the metropolitan show. Now, they must ultimately sacrifice the one or the other. This unpleasant circumstance arises from want of circumspection in those who arrange for the shows of the Royal Horticultural Society.—T. Jones, *Rusholme.*

[It is very unfortunate that the two great exhibitions of the Royal Horticultural and the Manchester Society should be held so near together, as the circumstance will, no doubt, cause great inconvenience to many, and disappointment to others who would be desirous of exhibiting at both places; but we are sure that it was not with any idea of interfering with the interests of any other society that the Royal Horticultural selected the period they have done for holding their show. For some years past the Council have chosen the week between the Derby and Ascot races as that in which to hold their great exhibition of the season; and as the Derby day this year falls on the 5th of June, had the Council adhered to their usual date the exhibition would have opened on the 12th, at the very time when the Manchester Show is open. We do not know what may have induced the change, but we should imagine that the Manchester Society having adopted the week of the Royal Horticultural may have induced the Council to hold their Show a week earlier to secure the time when London is full, instead of waiting till after the close of the Manchester Exhibition, when numerous visitors, whose attendance they might reasonably have expected to secure, will have left. It appears that the want of circumspection rests more with the Manchester Committee, who should first have ascertained

whether they were not taking possession of a date which was known to be that on which the Royal Horticultural Society usually held their great summer exhibition.]

NOTES OF AND ABOUT ROSES.

(*Continued from page* 47.)

5. Exhibition.—Public exhibitions of any flower afford a powerful stimulus to an improved culture of it; they also tend to spread abroad a more general knowledge of it, to raise it in the estimation of those who do not make it an especial object of cultivation, and, by bringing together specimens grown in different localities and on different soils, offer a ready means of comparison under different circumstances to those who do. This is pre-eminently the case with the Rose. There has never been a public exhibition of any particular flower that has attracted more spectators, excited more interest, or engaged so many persons in making it. It is, therefore, a matter of some importance that Rose shows should be so managed that the confidence of exhibitors should be secured, the excellence of their productions fairly and impartially recognised, and that the crowds of admiring visitors who throng them should be able to inspect the stands with as little inconvenience as possible, and without disappointment. These conditions secured in the main, Rose shows will continue to flourish for years to come.

It would be saying too much to affirm that these conditions are fulfilled, it would be equally wrong to assert that they are not. There is, therefore, a *media via*, which, though as stated of old, the safest, is wide enough,nevertheless, to admit of discussion, with a view of testing the soundness of what is believed to be good, and remedying what is thought to be defective. *Quot homines tot sententiæ*. Inviting the opinions of other correspondents interested in this subject, let us endeavour to discuss it calmly, without prejudice, and in a friendly manner. We may then hope to effect improvements where needed.

Rose shows have been found to be paying-exhibitions; the very important consideration of ways and means is hence set at rest. The next prominent points are the schedules, rules to be observed by exhibitors, and the judging of the specimens exhibited, to which may be added, as materially influencing success, the most appropriate time for holding the exhibition.

An equitable adjustment of the classes to the capacity of the various growers ought to be a primary consideration in compiling the schedules. I have before me most of the schedules of the Royal Horticultural Society, and of the Crystal Palace Company, for the years from 1861 to 1866; also, the list of awards, with two exceptions, of the latter, for the same period. For the earliest of these years the two schedules were nearly alike, differing only in the number of trusses required in the highest class for amateurs, being twelve more in the schedule of the Royal Horticultural Society than in that of the Crystal Palace Company, and this difference has been maintained ever since. There were also three classes in the former not inserted in the latter—namely, twelve trusses of Senateur Vaisse (open), twelve of any other kind (open), and eighteen of Tea-scented. After that year the divergence increases annually. Last year there were only six classes identical. While, however, the Crystal Palace schedules show no alteration, except in the number of Roses in pots during the six years, those of the Royal Horticultural Society became more elaborate and suitable to the progress of Rose culture every succeeding year, the schedule of last year being the best that has yet been framed by them. This speaks well for the Society, and shows that the Council, or those who compile the schedule, are fully cognisant of the increasing interest taken in Rose culture, and desire to give the full weight of the powerful influence of the Society in promoting it.

There is not, that I know of, nor should there be, any antagonism between the two shows. The same, or nearly the same exhibitors contribute to form both. There is, however, a difference in the number of visitors attending the two shows. Last year this difference was very marked; while the Show at Kensington was superior in many respects to that at Sydenham, the number of visitors who attended the latter was greatly in excess of the number at the Kensington Show. This circumstance should have some weight with the authorities at the Crystal Palace to induce them to revise their schedule for another season, if they wish to obtain a display satisfactory to the visitors, and at the same time deserving the confidence of exhibitors.

It will not be deemed out of place here to remark, that all who have seen and know the beautiful structure at Sydenham, must have learned with the deepest regret the sad calamity that has recently happened, by which a portion of the Palace has been, let us hope only temporarily, destroyed by fire. Whatever may be the arrangements for the forthcoming season affecting horticultural shows, the Company may rely on the sympathy and support of the horticultural body who have hitherto contributed to these Exhibitions, and as regards the Rose Show, the most popular of them, a considerable accession of strength would, undoubtedly, be obtained by simply adapting the arrangements to the requirements of the times.

The classes in the schedule may be reviewed under three sections—those assigned to growers for sale, to amateurs, and the open or miscellaneous classes.

As I hold it to be a primary consideration in the framing of the schedule, that the classes be arranged to meet the capacities of different exhibitors, I am impressed with the belief that the compilers of the schedules for the Rose shows acted upon this principle, by allotting the different numbers from ninety-six to twelve trusses to different classes, for the purpose of inviting the competition of growers according to their stock; of those growers for sale with whom Roses form one of the most important subjects of their business, as well as of those with whom they are only a portion of the general stock; for those amateurs who have time and space for the cultivation of several thousand plants, and can cut their forty-eight on any given day in the season, as well as for those who with less of either, yet feel the same pride in filling a box of twelve, on what to them is the eventful day of exhibition. If this was, as it ought to have been, the original object, it has been very decisively nullified. In the list of awards at the Crystal Palace Show, in 1861, will be found the names of sixteen different nurserymen among the successful competitors in the various classes, and eighteen amateurs. On turning to the last year's list we shall find but seven different nurserymen taking twenty-eight prizes; of these, five names well known in connection with Roses secured twenty-five prizes among them, the remaining three were taken by the other two: one a third, value 20*s*., and a fourth, value 15*s*., and the other a fifth, value 10*s*. In the same award we also find twenty-five prizes taken by eleven or twelve amateurs. The time chosen for the Show last year was rather too early, and probably influenced this result, but only slightly.

At the Show at Kensington, in the following week, when the time was more appropriate, the whole of the nurserymen's prizes, including most of those marked "Open," were taken by names now so familiarly associated with the Rose, but by no more of them than can be counted on the fingers and thumb of one hand. The reason of this has long been obvious. Those gentlemen who are usually known as the great Rose growers, by their sedulous attention to culture, their long experience, their enormous stock, and, generally, the favourable soil of their nurseries, have distanced all other competitors, and no restriction being placed on the number of classes in which one exhibitor may enter, the classes assigned to growers for sale have simply become a monopoly in their hands to be contended for among themselves. We all remember the marvellous flowers exhibited by these gentlemen, and the praises lavished upon them by the admiring spectators, and deservedly too.

Considering how much the great growers, or more correctly speaking such of them as exhibit, have done for those shows (for of late more than one respectable name has been missed), would it be just to introduce any restriction in the nurserymen's classes now, after being left so many years without any? Is it equally fair to shut out many respectable men who would be willing to enter into competition with their compeers? Herein is a knotty question. A similar inquiry may be made respecting the amateur classes. Of the four classes assigned to amateurs at Kensington, exclusive of one or two others in the miscellaneous section, entries were restricted to two. At the Crystal Palace there has been no such restriction, yet at Kensington it appears to have acted beneficially. Would a similar result attend a like restriction in the nurserymen's classes? I think it would, with some reservation, which is this—so much is due to those gentlemen into whose hands the whole of the nurserymen's prizes have by the force of circumstances fallen, that to introduce any restriction without some corresponding compensation, would not be dealing fairly with them, in consideration of what they have done in past years to render the shows successful and attractive.

Supposing the sum total to be applied for prizes to remain the same in the case of the Crystal Palace schedule, there is room afforded for such compensation. In open competition any place obtained is honourable to the competitor, especially if within the first four places; but no one, that I am aware of, sets a particular value on a fifth prize. At Kensington none of the prizes extend beyond a fourth. At the Crystal Palace seven classes are stretched out to a fifth. Let the fifth prizes be abolished. Again, Class 5 has hitherto been twelve varieties, one truss of each, for nurserymen only; and Class 14, for Roses in pots, confined to new Roses first sent out in the previous year. Neither of these classes is necessary, the first requiring too small a number from growers for sale, and the second being sufficiently provided for in the classes for new Roses and Roses in pots. If the sum applied to these classes, and to fifth prizes, were added to the prizes in Class 1 and 2, the highest for nurserymen only, the amount would not only cover what is assigned to Classes 3 and 4, but leave a margin to be applied to some other useful classes, or for the introduction of some new feature in the Show, as a class for Tea Roses, some single variety, Yellow Roses, &c.

By this arrangement, if the entries by one exhibitor be restricted to two classes, as they are for amateurs at Kensington, the great growers will lose nothing, so far as the value of the prizes is concerned. Or, if this restriction be objectionable, let Class 3 be for twenty-four varieties, three trusses of each, Remontant Hybrids only, as at Kensington, allowing competitors to enter for any three classes, thus leaving Class 4 to be competed for by small growers, if they decline to enter for the higher classes. It would do no harm to try the experiment of this slight restriction both at Kensington and the Crystal Palace.

A great improvement in the Show at Kensington was effected by the introduction of classes for Yellow, Tea, Noisette, and Moss Roses. Of six classes assigned to these, one at least appears superfluous. Last year, Class 14 was for twelve Tea and Noisette Roses, distinct kinds, for amateurs only; Class 15 was similar, but for nurserymen only; and Class 16 was similar, but open. The last might be dispensed with, the competition in all of them being as yet but very limited. Classes like these should be introduced into the schedule of the Crystal Palace Show.

As regards the number of flowers required in the several classes, the most objectionable is the ninety-six in the first class for nurserymen at the Crystal Palace. At Kensington, the greatest number required is seventy-two. I say objectionable, for although there are several hundreds of varieties in cultivation, yet if improvement is aimed at, and the selection kept within reasonable bounds by the rejection of inferior kinds, a lower number than ninety-six will effect the object, by bringing the very choicest together in the best condition. Ninety-six varieties are not wanted, nor do ninety-six varieties of equal merit exist, scarcely half ninety-six. It must not be inferred that all Roses specially pointed out as the best, should be after one uniform model; on the contrary, we desire variety in form as well as in colour; hence we have the cupped, globular, imbricated, &c., and this difference of form adds in no small degree to the pleasure and interest of cultivation. A globular Charles Lefebvre, or Chabrillant, and a Lord Clyde with the form of William Griffiths, would be very beautiful; but nobody would dream of excluding them because they are not so. Seventy-two varieties would include every perfect form and colour yet known.—Apollinus H. Kent.

(To be continued.)

PINCHING FRUIT TREE SHOOTS.

On looking over your Journal of December 18th, I see that "Theta," would like a little information respecting pinching and stopping fruit tree shoots. Perhaps my remarks may be of service to him,

My plan is to disbud a Peach tree as soon as the bud is well in leaf, leaving the buds after disbudding 5 or 6 inches apart, and each bud alternately above and beneath the twig or spur.

I never stop the shoots until they have five or six joints.

There is no fixed date to pinch or disbud a Peach tree. I have disbudded as early as February and as late as June. My trees here are so covered with the aphis as soon as they come into bloom that they lose all their first leaves in April, consequently they are a long time in making a second growth. Hence it is very late before they require disbudding, and I never stop the shoots until August, when I nail in and stop rather closely to expose the fruit to the sun. We have but little sun here after July, and I am glad to say I, like "A Constant Reader," was amply rewarded for my trouble with a fine crop of fruit, well coloured, but not quite up to the mark as to flavour.

I ought to have said my disbudding in February was in a Peach-house, and the fruit was ripe in May; but here my trees are all out of doors, facing south-east, and were not protected from frost in the least. Some trees that I have on a south-east-by-east wall were well protected with matting, and there was but a dozen Peaches on a wall 60 feet long by 14 high. So much for covering fruit trees.—T. Elcome, *Rhug Gardens, Corwen, North Wales.*

EARLY ROMAN HYACINTH.

This pure white and delightfully fragrant Hyacinth flowers in November at a time when scented flowers are very scarce. Each bulb produces three or four spikes of flowers, resembling a very large Lily of the Valley, and when half a dozen bulbs are planted in a six-inch pot their bloom forms a perfect bouquet. I, for one, can vouch for the justice of the recommendation made by Mr. Ker, of Basnett Street, Liverpool, having grown a quantity this season. The plant has been in bloom with us about two months, and has been very much admired.

From the low price of the bulbs I have not the least doubt that when better known the Early Roman Hyacinth will be much more extensively grown. Planted in large shallow pans, similar to those used for propagating bedding plants or growing Achimenes, the bulbs placed about 4 inches apart, when in bloom they are very beautiful. Visitors for the last three years in November at the shows at St. George's Hall, Liverpool, will remember how beautiful they were.—William Hill, *Keele Hall, Staffordshire.*

CASIMIROA EDULIS.

There is perhaps nothing so easy as to enunciate fine moral sentiments, except it be not acting up to them. So at least I thought when reading the article on Psidiums by "Radii, *Peterborough*," at page 44, where he says, "This assertion shows how careful people should be before they make a positive statement;" and yet at the end of his short paper, in referring to Casimiroa edulis he writes thus, "I see the above-named plant advertised by a London nurseryman, giving a flaming account of its capabilities of adapting itself to various situations. It may exist in the west of England in a sheltered situation, but it requires a stove to grow it in perfection, when it becomes a large bush, having numerous Apple-shaped fruit." Now, having a pretty general acquaintance with London nurserymen and their catalogues, I could recollect (and subsequent search has confirmed this), that Casimiroa edulis is only advertised by Mr. Wm. Bull, of Chelsea; and yet after all "Radii's" moral indignation at positive statements, it is certainly amusing to find that this London nurseryman gives no flaming account, but merely quotes the words of that eminent botanist Dr. Seemann.

Mr. Bull says, "This new fruit has been sent me by that zealous botanist and enterprising traveller, Dr. Seemann. In writing from Nicaragua he says:—'With other seeds I have the pleasure to send Casimiroa edulis, a large fruit like an Apple, which was brought to this country from Mexico by the soldiers and colonists of Montezuma, and of which you will see a figure in "Botany of the 'Herald.'" I fancy it may prove hardy in the southern parts of England, and might be introduced into Australia with the greatest advantage, as it is evergreen, and capable of standing any amount of drought and some degree of cold.'

"This fruit is described in 'Botany of the Voyage of H.M.S. "Herald," Flora of North-Western Mexico,' and thus spoken of:—'This tree has a remarkable tendency to accommodate itself to different climates. It grows from the lowest coast region to an elevation of 7,000 feet, producing everywhere an abundant harvest.'"

Now surely there is no flaming account by a London nurseryman here, but simply statements from two sources of undoubted integrity and scientific authority; and so far from any assertion as to its hardiness, Dr. Seemann only says, "I fancy

it *may* prove hardy in the southern [not western] parts of England," and adds that it is capable of bearing *some* degree of cold.

"Oh, wad some pow'r the giftie gie us,
To see oursels as others see us."

"Radnii," however, seems to have but little opinion of nurserymen in general, as he says again in reference to Psidiums, "No dependance is to be placed on purchasing them true." Surely this is rather hard; and I hope "Radnii" will not only adhere to his own excellent sentiments, but also be less disposed to join in the foolish cry that is too often raised against nurserymen for their glowing descriptions.—D., *Deal.*

P.S.—May I add here in reference to Mr. Scott's remarks with respect to Potatoes, that I thought I had mentioned the character of my soil, which, as he conjectures, is rich?

HARDY FLOWERS IN JANUARY.

Seeing your request for a list of flowers in each month, I ventured to begin on the 1st of this month, and then had gathered for me good specimens of the following:—Violets, abundant; Hepatica; Anemone (lilac); Aconite; coloured Primroses.

After being five weeks a prisoner in the house, I this day, January 24th, have been all round my garden and am delighted to find but little damage seems done, as all shrubs look well. Honeysuckles, Tartarian Honeysuckles, leaves opening; Ribes buds swollen; Mezereon buds quite pink; and if this genial weather continue the garden will soon be gay.—Mrs. F. Munn, *Rougham, Bury St. Edmunds, Suffolk.*

PEARS AND PERPLEXITY.

A friendly collision between Messrs. "T. R.," G. Abbey, and others, is like that between flint and steel, and the lookers-on are benefited by the sparks, which afford amateur fruit-growers like myself some little light to guide us through the too-often conflicting theories, assertions, and practices of various authors. We rise from the study of Du Breuil's excellent work convinced that a single vertical cordon is so simple, so effective, and beautiful, that we wonder we never thought of it before. We at once try the method, and painfully realise the difference between an English and French climate. Mr. Fish, enthusiastic on the subject, seems to anticipate the time when every cottage garden will boast its comely generous cordons; but Mr. Bréhaut, the most experienced, perhaps, and successful in this his peculiar system, gives a stern caution—It must be done in one way only; the shoots must be pinched at the right moment; walls so high must have so many leaders, the grosser-growing varieties more, the weaker fewer;—leading to the inevitable conclusion that, however beautiful and productive the system may be, there is no inconsiderable amount of care and observation to be exercised; and we rise from the contemplation of many publications with the feeling that in the multitude of books there is perplexity.

This perplexity has been increased just recently. In the spring of last year a long and able controversy seemed to decide that Pears on the Quince should not be allowed to emit roots from above the graft. Again we are in doubt. We are told to plant up to the graft, but not to cover it, and our trees came from a first-class nurseryman grafted 6 and 8 inches above the roots. What is to be done? for we must not on any account bury the roots so deep. Thus ordered to perform an impossible operation, we conclude such trees are improperly worked. In the case of some Jargonelle Pears I kept the roots near the surface; in two years the scion was twice the size of the stock, and the tree unhealthy; now the roots are buried, so in any case I am wrong, but see no help for it. Will "T. R.," or Mr. G. Abbey, or some other authority, increase our obligations by stating the limit of distance between graft and roots, whether such trees as I have described should be rejected, or whether the roots should be buried, or the stock hidebound as the alternative?

Another *quæstio vexata*—whether Pears on their own roots, and Apples on the Crab, are not better than on the Quince and Paradise, appears determinable by the size they are intended to attain and the soil they are to grow in, the latter being a fruitful source of differing opinions. For instance, in the garden of a friend there is a long row of bush Pear trees upwards of twenty years old; all those on the Quince are healthy and productive, all on the Pear cankered and decaying. His gardener advised me to plant nothing but trees on the Quince; within a month I was advised by another, who cultivated an opposite description of soil, to plant nothing but trees on the Pear.

Whilst thanking Messrs. "T. R." and G. Abbey for their recent articles, let me express a hope, that the discussion may be continued, so that we may have the promised experience of Mr. Abbey on the different results of budding and grafting, and other hints which are of much interest and benefit to such ardent novices as—C. C. E.

GREEN TURF.

I think "Forwards" has drawn largely on his imagination as to the cause of the injury his trees received in the turf soil. The larvæ of the cockchafer will eat the roots of trees, as the Surrey nurserymen know to their cost; but who ever heard of them in numbers sufficient to account for the havoc described, except in very light sandy or peaty soils? I, certainly, never met with them in large numbers in such soil as a Vine-grower would be likely to select. Then, again, would such larvæ if present be likely to be overlooked, great conspicuous fellows as thick as a man's finger? and if overlooked, how many would escape the paring and chepping of the turf, &c.? Those who know anything of these maraudera know how easily they are injured.

With regard to the larvæ of Tipulæ, I have seen the roots of Phloxes and herbaceous Pæonies eaten by them, and seen rooks busy pulling grass up to find the larvæ of Tipulæ feeding on the roots, but I have yet to learn that these larvæ ever eat the roots of trees; they may do so, but I have never found any injury of the kind I could trace to them; and I can assure "Forwards" that, though our "fine green turf" is not full of the grubs of the cockchafer, we have plenty of "daddy long-legs."

As to wireworms, like most farmers, I have suffered enough by their attacks to make me study their habits. Corn of all kinds and the Grasses in general they will eat, boring into their stems just below the ground, and eating their way upwards. Mangold Wurtzel in a young state, Turnips, Potatoes, and Carrots are eaten by them. In the garden, Pinks, Carnations, Daisies, Polyanthuses, and Primroses suffer from their attacks; but I never saw one at a tree root in the act of feeding, nor do I believe any one can prove they ever eat the roots of trees.

As is very well known, I have a good many acres of orchards, many of them fifty years old, and all but one are in grass. So plentiful are wireworms in the turf of these orchards that a sweet Pear, which has lain on the ground some days, may be often found with ten or a dozen wireworms in it: how is it they have not killed all the trees by eating the roots? Yet these trees look pretty well, at any rate a ladder of fifty staves will not reach the tops of some of them.

But, supposing wireworms injurious to Vines and trees in general, will leaving the turf some time cut on the ground, and then stacking it a year, get rid of them? I leave any gardener to answer the question.

When I write in "our Journal" it is with a sincere wish to add my mite to the general stock of information, thinking the readers ought to consider themselves as a mutual improvement society. I have seldom answered objections, leaving to others to discuss what I have advanced, being more anxious to lead others to think than anxious to force my opinions on them as incontrovertible truth. The Editors will bear me out in saying, that when I have taken exception to what others have written I have always signed my name in full.—J. R. Pearson, *Chilwell.*

THE PRINCE OF WALES POTATO.

We most of us admit, that we should speak of a man as we find him, and I do not see why we should not do the same of the Potato.

Living in a neighbourhood where there are at least five hundred acres of Potatoes grown annually, being a grower myself, and taking great interest in having the best sorts, I bought some of the Prince of Wales in 1865, for I saw this Potato advertised, certainly with a wonderful character.

I have not found it so good in flavour as I should like, nor is it a second early; but it is well up in all other points.

I planted it, as I have said, in 1865, had a heavy crop, but

like all other Potatoes that year, second growth occurred to it, and one-third was diseased.

I gave it another trial in 1866. I planted it on a piece of dry soil in drills 2 feet 6 inches apart, the sets 20 inches from one to the other. Lawes's manure was used on the sets. In the last week in July I took one plant up, and the Potatoes it bore weighed 6¼ lbs.; I was, consequently, tempted to take some up to send to the London market. On the 2nd of August I had a ton sent thither, and there were only 8 stones of small ones, which made in all 21 cwt., and the land which produced them measured only 9¾ poles. That ton of Potatoes sold in London for £6 17*s.* 6*d.* This is the Potato for me.—E. J. Atherton, *Nurseryman, Chatteris.*

PROPAGATING AND PRUNING BLACK CURRANTS.

For the benefit of amateurs I see Mr. Read has written some notes on the best way to grow Currants. I think he has gone on very well until he came to the Black Currant, as to which I am sure he has made some mistakes. Thus, I infer that he intends the cuttings to be made in the same way as those of the Red and White. I am sure that there are many growers who will coincide with me in saying that that is one of the greatest of mistakes, for if so made half of the head will often die from some unknown cause.

My plan is to put the cuttings in with all the buds on them, say four or five, leaving one above ground. Next autumn cut all the shoots down to two eyes; by doing this you will have eight nice strong shoots which will bear a few bunches of fruit. The plants are now fit to plant out permanently; set them in rows 5 feet by 4 feet. A row of Cabbages may be planted between them for two or three years; plant the Cabbages early and they will come off before they can interfere with the Currant trees. In the following autumn cut off the foremost shoot to the next lower one, and so continue every year. Never let more than two or three years' growth be on one shoot before you cut it to the ground (if there is no shoot to take its place, cut it to the next shoot lower down), and if a shoot die you have two to take its place, which will spring up from the ground.

After a few years, if your bush become too large and the shoots extend too far in the rows, take the spade and chop them off closely with roots to them, and if you want to make another row they will quickly form good plants for the purpose; you will save two years by using them. Be sure never to cut off the top of any shoot if it is too long, cut it out altogether; never be afraid to cut out plenty of shoots, for the Black Currant likes plenty of sun and air, and does not succeed so well as the Red Currant in the shade. In fact, the Black Currant is as different from the Red and White as the May Duke Cherry is from the Morello, the older and more shrubby the tree the more and better the fruit; but on the Black Currant, like the Morello, all the young wood should be preserved, and no topping is wanted.

I could show Mr. Read a large number of Black Currant trees, among them some which have been planted about twelve years, and not one more than 3 feet high and 10 feet across. I do not remember a single plant in the plantation having died out. I find by well thinning the trees out, giving plenty of manure every year, and growing none but the Black Naples, that the fruit will make a very pretty dish for the table, and especially where no Grapes are grown. The fruit is both large and sweet, and I have seen bunches 4 inches long with as many s twenty berries on them.

I wonder Mr. Read did not offer some remarks about the Gooseberry, with respect to which information is not less needed than in the case of the Currant. I treat them in the first place as he does the Red Currant; but, as in the case of the Black Currant, after the third year I never shorten the shoots I intend to bear, unless it is one that has grown too far out of the way.

I think it is a wrong system to cut every shoot to about 3 or 4 inches; of course, from every shoot so cut you must expect three to spring, and very little fruit, and in the following spring you have a hedge. On my system, leave the leading shoots about 6 inches apart; cut everything else clean out, and do not shorten the shoots. In the following season you will have one or two shoots from that left, and plenty of fine fruit; cut the old shoot out leaving one of the young ones for the next season, and so on every year.

As to Red Currants we can always find plenty of vacant spots for them on the walls. Against walls too low for anything else, and with any aspect, wherever there is a space of 2 feet to spare, there the Red and White Currant are planted. Train the branches 6 inches apart, and prune them just as Pears and Plums.—J. T.

CUCUMBER FAILURES.

For years I have been a grower of Cucumbers, and have many times witnessed that we cannot, even under the best of treatment, insure the best results. I have some Cucumber plants showing fruit; they have been looking well and are now, only, it may be, one of the best and healthiest-looking plants will to-day show symptoms of flagging in part of a leaf, or a whole leaf, as if wanting water; to-morrow perhaps other leaves and footstalks hang drooping; next day one or two more, and so the evil goes on for weeks and the plants cannot be said to be either alive or dead. Of the leaf that flagged first the footstalk will again become stiff, but the blade will be wholly gone (crisped up). From the first symptoms the plants make little or no growth; sometimes I have known them break from the stem, but the foliage so produced only shares the same fate as the older leaves. Leaf after leaf suffers until the whole of the foliage is gone, and the plant is good for nothing.

I have repeatedly taken up the plants and examined them, sometimes there is a partial decay of roots with the stem looking well and healthy; at other times the stem and all the roots appear to be attacked, and then, of course, the plants die quickly.

In my Cucumber-houses the disease generally takes the winter plants just as they are beginning to bear, about this time —say January and February. In March and April, when the days are longer, the plants have not suffered in the houses; but I have had the ridge Cucumbers in the summer months out of doors affected in a very similar manner for several seasons.

I have tried all kinds of changes of soils and seed, but to no purpose. I have never seen any one's plants do as mine have done. I have been where Cucumbers were grown almost throughout the year, I have mentioned the evil to others, and showed my plants, but have never yet met with any one who has experienced the like.

My houses are heated with hot-water pipes for top heat, and there are cement tanks under the beds, with hot-water pipes running through, for bottom heat. I can have plenty of heat, the range being from 60° to 80°. Our houses have not been below 60° during this cold weather.—An Old Subscriber.

[We have experienced the same evil, especially in winter, and when the plants were grown in low pits, and have generally traced it to too much heat at the roots, and too much moisture at a season when the processes of evaporation are very irregular; a good layer of rubble between the tank and the soil might help. We seldom meet with this complaint in houses where the light strikes freely to the bottom of the Cucumber plants, and where there is room to have the soil in a rather steep ridge instead of as a flat bed. Where, as in your case, there is plenty of heat, a steep roof, even a rather steep span-roof, is best for winter Cucumbers. Many plants fail about this time that have borne up to Christmas. What say other correspondents ?]

ON PRUNING CEDRUS DEODARA.

[The following is extracted from "The Gardener," a new series of the "Scottish Gardener," edited by Mr. William Thomson, of Dalkeith Palace Gardens, and which promises to be a most excellent monthly publication.]

The Deodar or Temple Tree has now become a favourite all over Great Britain. The parks and pleasure-grounds of the wealthy, the metropolitan parks and cemeteries and town squares, as well as villa and cottage gardens, all boast of their Deodar Cedars. Many of these trees are in a faultless state; still large numbers of them are to be seen in a sad and apparently neglected condition; but all are capable of being brought into shape by a free use of the knife, and for this end I propose giving a few practical hints.

The Deodar was first introduced into Great Britain by the Honourable William Leslie Melville during the year 1831, from seed collected on the Indo-Tataric mountains, at an elevation of 10,000 or 12,000 feet above the level of the sea, where it attains a height of 180 feet, and sometimes even 200 feet,

having stems from 24 to 30 feet in circumference. Few plants were introduced at first, and these primary or original trees are now noble specimens of their kind.

As cuttings of the Deodar are very freely produced under certain circumstances, a large proportion of secondary trees were soon obtained. Afterwards the Honourable East India Company gave liberal encouragement to their introduction, and through their instrumentality a large quantity of seed was annually imported. About fifteen years ago it was the wish of our Government to have them introduced on a much larger scale for forest planting, when upwards of a ton weight of seed was sent home, raised in various nursery establishments in the three kingdoms, and afterwards planted out for this desirable end.* A great drawback, however, to the forest extension of the Deodar was the loss sustained during the unprecedented winter of 1860-61, which injured a large proportion of trees in various soils, but chiefly in damp situations. The state in which certain trees were at the time, caused by late growths, brought on by a warm, moist autumn, and succeeded by a frost, the severity of which was almost unknown in Britain—viz., 3° below zero, was considered by many as the cause of their destruction; but from a careful investigation of the affected trees, I came to the conclusion that many of the Deodars during the above winter were injured by the heavy fall of snow we then experienced, forcibly bending their long projecting branches towards the ground, thus rupturing the vessels; and while in this condition the injured vessels along the upper surface of the branches became exposed to the severe temperature, while other trees growing side by side sustained no damage whatever. This observation was found peculiarly applicable when examining pruned and unpruned trees. In almost all cases the former were saved, while the latter, particularly those with long horizontal branches, were more or less destroyed, although several were more than 15 feet in height.

The pruning of the Deodar, although practised in some large establishments, is, perhaps, not so generally adopted as it ought to be. For the information of inexperienced cultivators I beg to offer the following remarks. For many years past, and even at the present time, it has been considered vandalism to touch a Deodar, or even any species of Conifer, with a knife. This common but false notion has been the cause of so many of them getting out of shape by taking breadth instead of height, and many assuming numerous leaders. In its native state the Deodar is found growing in large forest groups, where the lower branches are rarely seen, being all decayed from close confinement, which causes them to grow upright. When planted singly, as is generally done in this country, they naturally branch to the surface of the ground.

From long experience and practice in the pruning of the Deodar, and judging from the beauty which many of the trees so treated have assumed, I am decidedly of opinion that pruning should be done at a very early stage of the plant's growth, and continued in a limited degree for a few years afterwards, for if once put into proper shape it is likely to retain it. Several millions of Deodars have been planted over the country, and little has been done to improve them. It is now high time that many of them should be operated on, seeing that it can be done with safety. I never saw a plant injured from judicious pruning, whether 3 or 30 feet in height, provided it was done at a proper season. The best time for pruning the Deodar is after the summer growths are matured, which is generally the case after the second week of August. Any time after this period pruning may be done with perfect safety, and continued throughout the autumn and early winter months, September and October being, however, preferable for the purpose. The Deodar always looks best when it has a pyramidal shape; and the most unsightly, if carefully operated on, can sooner or later be made to assume this form. Supposing a plant, 6 or 10 feet high, having several leading tops, fix on one for a leader as near the centre of the plant as possible; all others must be cut out, and the plant afterwards freely trimmed-in all round, beginning at the bottom and working upwards. The lower branches, no matter what their thickness, should be all equally shortened by introducing a sharp knife below, and cutting them off upwards and outwards, as well as all the branches below the level of the eye. All the upper branches should be cut from above, outwards and downwards. By a rigid adherence to this treatment no cut portions are exposed to view. The secondary or side branches should also be cut in the same way, and so on till the whole plant is made to assume a pyramidal shape, which is, indeed, its natural form of growth. Care must be taken to have any stray shoots removed from the side of the leader, which, in its natural and perfect state, is always bent downwards. In no instance attempt to tie the leading shoot upright, as it will be found that it will erect itself during the following season. Some ill-shaped plants may be disfigured for a time from excessive pruning, but this, from the distorted state of some of them, is absolutely necessary. The next year's growth, however, will soon bring such trees into proper training.

One large plant known to me was 30 feet in diameter of branches on the surface of the ground, and 20 feet in height, and had all its lower branches, although 1½ inch in diameter, cut so that the tree was reduced to a diameter of 20 feet at the bottom. All the other branches were shortened-in as above described till the tree was cut into a pyramidal shape. Previous to pruning the terminal shoot of this tree was barely making way. A year or two after the pruning was accomplished it began to grow freely, and the numerous pendant growths annually made have given to this tree a very graceful habit, and justly entitle it to the name of the Fountain Tree, now generally given to the Deodar.

After being once properly cut into shape it is seldom necessary to give the Deodar any after-pruning, unless to remove duplicate leaders that may be forming. If in after years it should be found that one side of a tree is bulging out more than the other, a free use of the knife will soon put all right. After pruning some ill-formed trees it is not an uncommon practice, in order to give gracefulness to the tree, to have the centre or leading stem tied upright. This ought to be avoided, as the pressure caused by the tie will very soon indent the bark and gradually work into it, causing the upper portion above the cord to become yellow, and ultimately decay.

It is a remarkable fact that those trees which stood best the severe winter of 1860–61 are those cuttings and seedlings which had been freely pruned at an early period. The growths on these were numerous and short, and resisted bending with the heavy snow, which was found to be so fatal to those trees where pruning had not been resorted to.

For many years, as before stated, cuttings of Deodars were freely made and distributed, and at the present time it is easy to tell trees produced from cuttings from those reared from seed. The branches of all the cutting-made trees generally come out horizontally all round the stem, composed of irregular whorls having intervening spaces, with points and side branches all pendulous. If such specimens are left to themselves they never will assume the compact form of seedling plants. Although the cutting-made trees with horizontal branches suffered most during the heavy snow and frost of 1860–61, such trees, when freely lopped in, can soon be made to assume a very different habit, so as to resist a heavy fall of snow, becoming thus not liable to have their vessels ruptured, and thus become a prey to frost.

Several of those most injured in the Botanic Gardens were reared from cuttings taken from one of the original trees introduced by the Hon. William Leslie Melville, and now growing in the garden. This original tree had its lower branches much bent down and injured with the weight of snow. A free pruning during the following autumn put this fine tree all right again. About the year 1856 the large tree was much cut in to keep the branches from interfering with two walks, which operation greatly assisted to protect it. If the trees totally or partially killed (at least all above the snow-line 2½ feet), had not been produced from the large tree, it might have been inferred that they were cuttings taken from a tender variety. Unpruned plants from cuttings taken from the original tree, standing both on high and low situations, suffered equally.

For the purpose of pruning large Deodars, I find the best method is to have a large tress, 6 feet high and 5 feet long, having no spars on one side, so as to stand close against the tree, while the other side has cross-rails arranged in the form of a ladder, having the upper step 6 inches broad, so as to enable the operators to stand on it. By means of this tress

* The seeds alluded to were divided between the nursery establishments of Messrs. Glendinning, of the Chiswick Nursery, London; Messrs. Skirving, of the Walton Nursery, Liverpool; and Messrs. P. Lawson and Son, Nurserymen, Edinburgh, to raise them for the Government plantations. The quantity reared in the Edinburgh nursery was very large in proportion to those raised in the other establishments, no doubt owing to their being sown broadcast in open-air beds, for the first time in Europe, instead of employing pits and frames, as was adopted in London and Liverpool. Those individuals who witnessed the extensive beds of Deodar seedlings in the Golden Acre Nursery, sown and reared under the able management of Mr. P. S. Robertson (now of the Trinity Nursery), will not soon forget the sight. The beds were prepared and sown as if for Scotch Fir or Larch.

the pruning 12 feet up can easily be done; but for higher pruning it is necessary to place a stout ladder against the tress, held firm at the bottom, up which the operator can ascend and prune a tree from 20 to 25 feet in height. If the pruning of a still higher tree is required, it is necessary to have two strong ladders of unequal lengths, so that one may lean upon the other, and thus be held firm against the side of the tree and moved round as the pruning goes on.

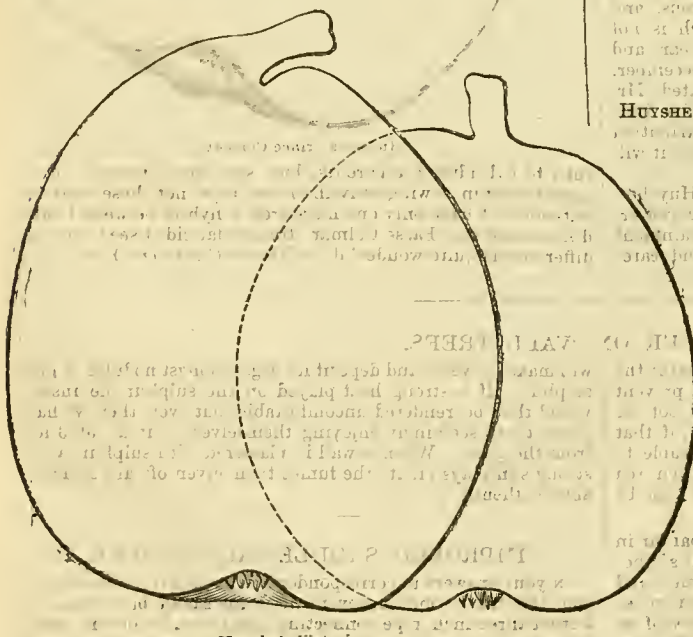
The Deodar is now becoming a favourite tree to plant on grass in front of villa residences, and if treated as described it will soon become a picturesque object. Such trees should always be protected with a wire fence, as many planted in such situations get injured by dogs, and are never replaced, from an idea that they will not succeed.—J. M'Nab, *Royal Botanic Garden, Edinburgh.*

THE ROYAL PEARS.

The Royal Pears have a just claim to such a title. Raised as they were by the descendant of ancient royalty, introduced as they have been at the table of royalty, and bearing as they do right royal names, what better claim could they have to such a designation? In their origin, too, they are no haphazard mongrels, but individuals of high descent and noble pedigree.

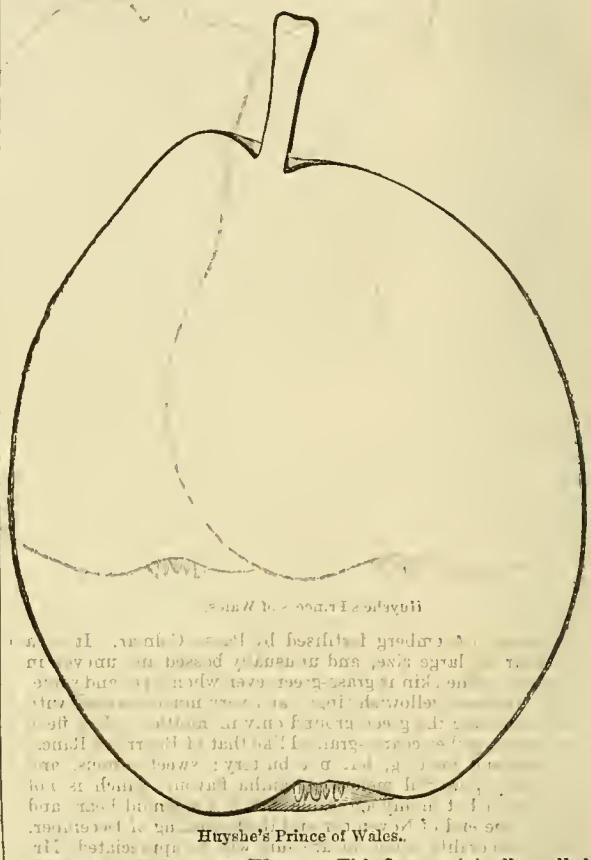
It is to the Rev. John Huyshe, of Clythysdon, near Exeter, that we are indebted for these valuable additions to our pomological collections. "It is now about thirty years, or rather more," writes Mr. Huyshe in the autumn of 1864, "since I began the practice of hybridising Pears, and the effects have been peculiarly striking. From Marie Louise hybridised with Gansel's Bergamot, I obtained three pips from one fruit, and the produce of these were respectively the Pears now known as Victoria, Prince of Wales, and Princess of Wales." In a previous letter of the same year he says: "I send you another Pear, a seedling, being a hybrid between Beurré d'Aremberg and Passe Colmar. It has borne fruit this year for the first time, and what it may be of course I know not, but it seems to promise to be good." It did prove good, and I was subsequently informed that "Mrs. Huyshe wishes it to be named Huyshe's Prince Consort, in memorial of one whose character she greatly admired."

Such, then, is the origin of these four fruits which we have now the pleasure of introducing to our readers, and of which the following figures and descriptions will furnish a good idea of their characters and qualities.



Huyshe's Victoria.

Huyshe's Victoria.—This and the following made their appearance in public much about the same time, and at once took their position as fruit of high merit. In form Victoria is very characteristic. The two shapes which it usually assumes are represented in the accompanying figure, where it will be observed that one is very similar to Beurré d'Aremberg, with the very oblique stalk; while the other has the stalk inserted in a line with the axis, and is particularly short and stout. The skin is of a yellowish ground, and freckled and veined all over with thin, smooth, cinnamon-coloured russet. The flesh is yellowish, sometimes a little gritty at the core in dry seasons, and melting, very juicy, rich, sugary, and vinous. It is in use during December and January.

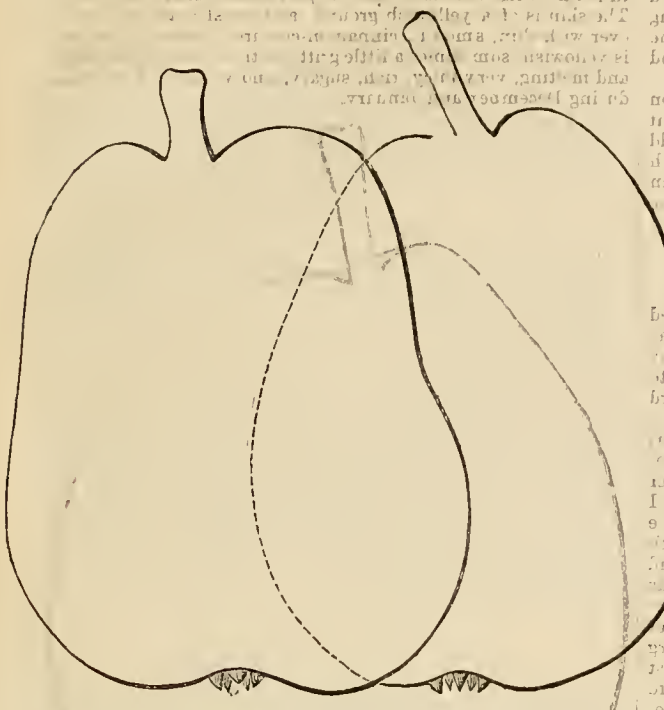


Huyshe's Prince of Wales.

Huyshe's Prince of Wales.—This was originally called Huyshe's Bergamot, not because it is at all like a Bergamot, but because the flavour bears some resemblance to that of its male parent—Gansel's Bergamot. On it being represented to Mr. Huyshe that such a name was at variance with the appearance of the fruit, and might tend to mislead, he at once consented to the change, and it has now for some years been known as Huyshe's Prince of Wales. The fruit is large, sometimes immensely so; and we have seen it grown against a wall as much as 4 inches long and 3½ in diameter. Its ordinary size when well grown is that represented in the figure. The skin is of a lemon yellow ground veined with cinnamon-coloured russet. Eye small for the size of the fruit, and open. Flesh yellowish, tender, and fine-grained, melting and very juicy, richly flavoured, and with a high aroma.

Huyshe's Princess of Wales.—This is the third of the produce of the "three pips from one fruit," and like Victoria varies much in form. Sometimes it is quite cylindrical and pinched in at the middle with a sort of waist, even more so than is represented in one of the figures. The skin is like that of a handsome Marie Louise, with a smooth lemon yellow ground colour, sprinkled with patches, veins, and dots of pale cinnamon-coloured russet. Flesh of a deep yellow colour; and in specimens received from Mr. Huyshe in 1865, was very melting and abundantly juicy, fine-grained, richly flavoured, and with a very high aroma. That same season it was presented to the Princess

of Wales at Sandringham, who was graciously pleased to express herself very highly of its great merits. It is ripe in the end of November.



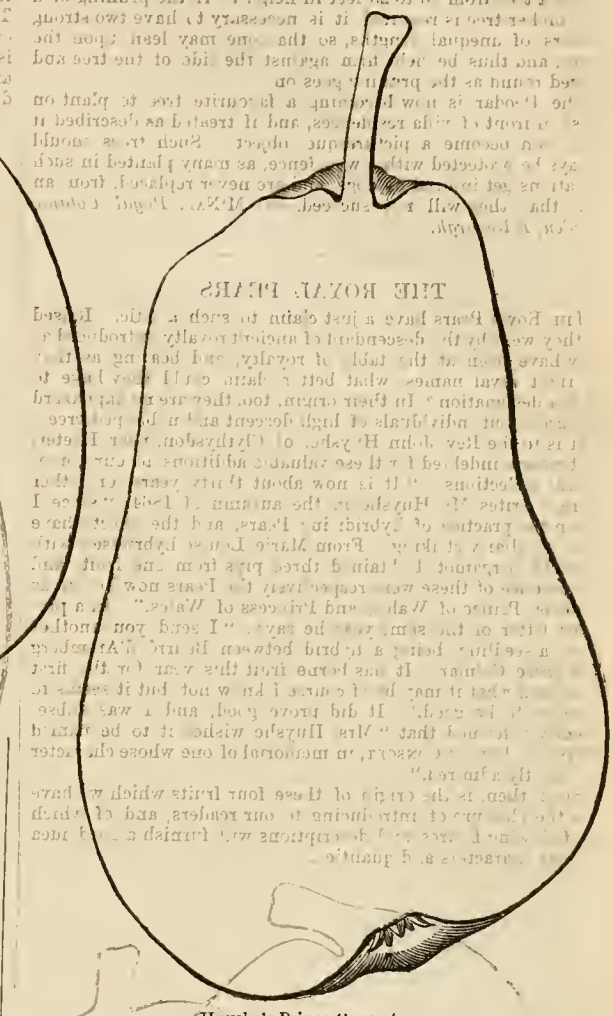
Huyshe's Princess of Wales.

from Beurré d'Aremberg fertilised by Passe Colmar. It is a noble Pear, of large size, and unusually bossed and uneven in its outline. The skin is grass-green even when ripe, and sometimes acquires a yellowish tinge, and very much covered with russet, exposing the green ground only in mottles. The flesh is yellowish, rather coarse-grained like that of Beurré de Rance, very juicy and melting, but not buttery; sweet, vinous, and with a very powerful melon or vanilla flavour, which is not only peculiar but highly agreeable. It is a splendid Pear, and ripens in the end of November and the beginning of December.

With a liberality which we are sure will be appreciated, Mr. Huyshe has presented the entire stock of this admirable Pear to the Royal Horticultural Society of London for distribution among the Fellows. [Young trees as well as cuttings of it will be balloted for on the 5th of February.]

Such a measure of success as has attended Mr. Huyshe's efforts rarely falls to the lot of hybridisers. It is, however, but the reward of intelligence well directed to the attainment of a certain end. Not only is it necessary to select and carefully to hybridise the parents, but, says Mr. Huyshe, "I am careful now in sowing only the *round* pips, not those that are flat-sided. I have only one more tree, a hybrid between Beurré d'Aremberg and Passe Colmar, from a flat-sided seed, and the difference is quite wonderful."—(*Hogg's Gardeners' Year Book.*)

Huyshe's Prince Consort.—This is the most recent of Mr. Huyshe's seedlings, and, as has been already stated, is of a different parentage to the three preceding, having originated



Huyshe's Prince Consort.

RED SPIDER ON WALL TREES.

I have long used a wash with soft soap in it to paint the trees, and it answers admirably, though it does not prevent red spider. Can I not, by mixing with the lime and soot for washing the wall some small proportion of coal tar, or, if that would be injurious, say of some other stuff as disagreeable to insects, form a poisonous wash, which would deter even red spider from laying eggs on the wall, and at the same time be innocuous to the trees?—H. H.

[It will not do to mix even the smallest portion of coal tar in your wash for the walls. It would be injurious until so thoroughly dried that it would give off no deleterious fumes, and when it came to that condition it would not deter red spider and other insects from depositing their eggs. We know of no material, poisonous or otherwise, that will keep insects from doing so, as the substances which would deter insects would, we fear, also hurt vegetation. You rightly judge that red spider is deterred by sulphur, but that is chiefly by the fumes sent off by heat, as the red spider will be as merry as possible, will make its webs, and deposit its eggs amongst nodules of pure sulphur. If a strong heat played on the sulphur the insects would then be rendered uncomfortable, but even then we have found them seemingly enjoying themselves on it about 3 feet from the glass. When a wall is plastered with sulphur, and a strong sun plays on it, the fumes then given off are disagreeable to them.]

IMPROVED SADDLE-BACK BOILER.

In your answers to correspondents at page 491, December 25, you state that "one improvement of the saddle-back would be a stout three-inch pipe connecting the two sides of the boiler at the end farthest from the furnace door; . . . one tap would then empty the boiler." I have seen this plan adopted several times in different places, but it always proved unsatisfactory. The pipe, being so much exposed to the direct action of the fire, soon gave way, and, of course, a flaw in any part is fatal

to the whole. The pipe was burnt away while other parts of the boiler were comparatively good. All the advantages of a connecting pipe, and others, are secured in the terminal saddle boiler without this serious drawback. The water freely circulates between the back piece and the sides, both top and bottom, so that a tap fixed in any part effectually empties the whole. Mr. Abbey, speaking of this boiler, says (Vol. X., page 326), "This is the greatest stride made for a long time in heating by hot water with the saddle boiler."—T. J.

THE ROYAL HORTICULTURAL SOCIETY'S EXHIBITION AT BURY ST. EDMUNDS.

The following is the official list of the special prizes which will be offered for competition at the above Exhibition :—

	£	s.	d
Royal Horticultural Society.—A Silver-gilt Cup, for the best and most effective group of 20 Plants—10 Foliage and 10 Flowering plants	25	0	0
N.B.—These will be arranged by the exhibitor, and in accordance with his own taste; he will be required to find his own stands if he considers them necessary.			
County Cup, for the best 9 Fuchsias in 13-inch pots	7	7	0
County Cup, for the best Stove or Greenhouse Plants in Flower	3	3	0
County Cup, for the best 3 Pine Apples, distinct	5	5	0
Ladies of Bury —Silver Cup, for the best 12 Orchids	20	0	0
Second Prize.—Silver Cup, for 12 Orchids	7	7	0
Town of Bury.—Silver Cup, for the best 12 Ferns, native or exotic. Pots not to exceed 12 inches in diameter. (Amateurs.)	10	10	0
Town of Bury.—Silver Cup.—12 Ferns, native or exotic. (Nurserymen.)	10	10	0
Town of Bury.—Silver Cup, for the best 6 Lycopods, distinct	5	5	0
Town of Bury.—A Watch or Cup, for best 3 Window Plants, grown by a Mechanic or Labourer	3	3	0
Town of Bury.—Silver Cup, for the best three groups of Fruits and Flowers for the decoration of the dinner table	10	0	0
N.B.—It is not necessary that Fruit and Flowers should be mixed in all the groups. The prize will be awarded by a jury of ladies.			
The Borough Members for Bury.—Silver Cup, for the best Hand Bouquet for Ladies	6	6	0
Second Prize.—Ditto	4	4	0
These prizes will also be awarded by a jury of ladies.			
Ipswich Town Cup, for the best 6 pot Vines, in fruit, 3 kinds..	5	0	0
Ipswich Town Cup, for the best 12 Orchard-house Trees, in fruit, not less than 6 distinct kinds. It is not necessary that the fruit should be ripe in this class	10	0	0
Eye Horticultural Society.—Silver Cup.—For the best 24 Cut Roses on single stems, grown by an amateur, a member of any Horticultural society in the County of Suffolk	10	10	0
Town of Stowmarket.—Gold Medal, for the three heaviest bunches of Grapes	10	10	0
Woodbridge Horticultural Society.—Silver Cup, for the best 12 cut blooms of Picotees, grown by an amateur	5	5	0
Suffolk Gardeners' Silver Cup, for the best 12 Cut Roses, grown by a Suffolk Gardener	5	5	0
Second Prize for Ditto.—Silver Cup	3	3	0
Suffolk Gardeners' Silver Cup, for the best 12 Seedling Variegated Pelargoniums of 1866 and 1867	10	10	0
Suffolk Gardeners' Cup, in honour of Mr. D. Beaton, for the best collection of Bedding Plants	5	5	0
Rev. Frederick Cheere, President of the Bury Horticultural Society.—Prize, for the best 12 Pelargoniums, Show or French	10	10	0
Mr. Samuel Barrett Hardwick.—A Watch, for Cottagers, for the best collection of Vegetables	3	3	0
Mr. Samuel Barrett Hardwick.—A Prize, for the best-cropped and best-kept Allotment Garden within the borough of Bury	1	11	6
Second Prize, for the second best ditto	1	1	0
Thetford Horticultural Society.—Silver Cup	10	10	0
Gardeners' Chronicle Prize.—Silver Cup.—For the best collection of Fruits and Vegetables, made up as follows:—Of Fruits, any five of the following eight kinds: Grapes, Melons (2 fruits), Strawberries, Gooseberries, Currants, Raspberries, or Apples (of the crop of 1866). Of Vegetables, any eight of the following fourteen kinds—one basket or bundle of each:—Peas, French Beans (or Scarlet Runners), Broad Beans, Cauliflowers, Cucumbers (1 brace), Summer Cabbages, Early Carrots, Turnips, Artichokes, Onions, Spinach, Rhubarb, Potatoes, or Mixed Salading	20	0	0
Journal of Horticulture Prizes.—Two first Prizes of the value of £10 10*s.* each.—For the two best Desserts, consisting of not less than seven kinds of Fruits of 1867, arranged as for the table, combining quality of fruit with taste in arrangement.—Open to Gentlemen's Gardeners and Amateurs only	21	0	0

NOTES AND GLEANINGS.

Judging from the number of letters we have received from subscribers complaining that they did not receive their last Number on the usual day of publication, it would appear that they did not observe the announcement in the previous Number that that day would thenceforth be Thursday. This, which was the original day of publication, was abandoned for a time to meet the convenience of a former publisher; but the reasons for publishing on Tuesday having ceased, and the day itself being exceedingly inconvenient from its following so soon after Sunday, we have determined that in future the day of publication shall be Thursday.

—— The Anniversary Meeting of the Royal Horticultural Society will be held at South Kensington on the 12th of February at three o'clock for the election of the Council for the ensuing year. We find the retiring members to be Sir Arthur Buller, Hon. William Cowper, and Mr. Wilson Saunders; and the gentlemen who are recommended as their successors are, Hon. C. Grey, Mr. Wentworth Buller, and Major Trevor Clarke. It has been said, "There is no Rose without a thorn;" and while we have reason to congratulate the Society on the return of an ardent horticulturist in the person of Major Clarke, by an inexorable law we have to regret the loss of Mr. Wilson Saunders, without whom in its councils none of our metropolitan scientific bodies seems complete. Let us hope that by another revolution of the wheel of time the hour will come when we shall again have the benefit of his great experience and mature judgment.

—— A substitute for the ordinary cloth shreds for nailing trees to walls has been sent us by the Rev. W. Kingsley, of South Kilvington, which for durability is infinitely superior to that article. It consists of the clippings or refuse of the india-rubber cloth, of which india-rubber hose and similar articles are made. Besides its durability and perfect pliancy, it has the advantage that it can be cut into shreds of the narrowest width, and may even be made into thongs by which small shoots can be tied. We believe it is made at Leeds, but wherever there is a manufactory of india-rubber fabrics, it will, in all probability, be obtained.

WORK FOR THE WEEK.

KITCHEN GARDEN.

Trenching and manuring must now be carried on in a systematic manner. Every piece of ground that becomes vacant should not be trenched and manured indiscriminately, but with reference to the future crops; some of these will require no manure, others need much, and almost all require some peculiarity in the mode of preparation. Lose no opportunity of bringing the soil into good working condition for the crops which must soon be committed to it. A generous soil always pays well for the extra labour of frequently turning and knocking it about. *Asparagus*, a fresh bed should now be planted; a very considerable proportion of leaves should be used in the formation of the bed. The beds in cutting should have air freely admitted during the present mild weather. *Beans*, a crop should be planted in boxes or pots, which should afterwards be placed in a forcing-house. At the same time, a crop should be planted in the open air, when the ground is in good condition. *Carrots*, make a sowing of Early Horn on a slight hotbed, either to succeed the former sowing recommended, or to come in for a first crop. When the soil is light and dry, a sowing may be made on a south border. *Cucumbers*, as soon as the fruiting-bed is ready for the plants, make a hole in the dung beneath the centre of every light, and lay a few fresh-cut turves in each; afterwards lay a sufficient quantity of light soil upon them to raise the plants, when planted, near to the glass, then cover up and give air according to the state of the bed. *Onions*, those who are short of old ones, or who wish to grow some to a large size, should now sow White Spanish in a box, which should be placed in a forcing-house. The Underground sort should now be planted. *Peas*, sow in pots or boxes for planting out in March; also, sow two crops in the open garden, one of an early sort, the other of an approved sort, which does not come in so early. *Radishes*, sow another crop in a frame, where there is a little bottom heat, or they may be sown where Potatoes are planted. A crop should also now be sown on a south border. Cut and prepare Pea-sticks for use; lay them flat in heaps, and place some weighty logs upon them to press and keep them flat and spreading.

FRUIT GARDEN.

When orchard trees are infested with insects or moss, the bark should be well scraped with a blunt tool, to remove as many of the larvæ of insects as possible, after which the parts should receive a coat of hot lime and soot in equal quantities, mixed with urine until it attains the consistency of thick paint. This composition should be well rubbed into the crevices

of the bark, in order to make sure of its reaching every hiding-place of the enemy, and if a little cow-manure were worked up in the composition, it would be useful in causing it to adhere better. It is a tedious process to properly cover large, old trees with this, but its effect in clearing them of insects will repay the trouble, and an occasional coat to young trees will be useful in keeping them clean. Where Filberts are brought under the dominion of the knife and spade, which is by far the best method of cultivating them, let all suckers be effectually removed, and let some manure be forked in about the trees. Shorten all the strong shoots of last year's growth, but do not interfere with the small ones, as it is from these that the nuts are principally produced. It is better to thin out the large branches if they are crowded with wood.

FLOWER GARDEN.

In the absence of frost, prune hardy Roses; reduce the wood according to the luxuriance of the tree, but take into consideration its tribe and habit. Finish planting the hardy sorts, and protect their roots. If the removal of evergreens has been neglected, it may be performed during mild, moist days. Preparation should be made in the pinetum to receive any proposed addition to the collection. If the natural soil be indifferent, trench it to the depth of 3 feet, and allow a diameter of 6 feet, raising a mound 18 inches above the surface to receive the plant; a compost of turfy loam, decomposed vegetable matter, and sand, may be advantageously employed. The late severe frost will test the hardiness of our late importations of Coniferæ.

GREENHOUSE AND CONSERVATORY.

The continuance of unfavourable weather will not allow of any essential variation of temperature here. The precautions previously recommended in regard to allowing exterior circumstances to govern in a measure the temperature within the house may be insisted on. Should high winds prevail, little air need be admitted. Few of our glass houses are so constructed as totally to exclude air; aided by the pressure of strong currents, it will be insinuated through every crack and crevice, and the necessity for admitting it by other means obviated. Cinerarias and Calceolarias will require a liberal supply of water, and possibly increased pot-room. Pelargoniums must be cautiously encouraged to activity. The soil intended for greenhouse plants should be prepared and sweetened by several turnings, and a sufficient supply for immediate use should be stored in an open shed. Heaths have a beautiful habit of growth, and where a tolerable collection is kept some are in bloom every day in the year. If any free-growing variety requires a larger pot, repot it by all means. Water with care, give air freely. Be particularly cautious with fire at all seasons, even when frost occurs it must be very moderate indeed. At this season many species of Epacris, Pimelea, Correa, Polygala, and Boronia are in great beauty. As they go out of flower cut them back, clear them of their dead flowers, and place them in the cold pit. Where Orange trees are grown to decorate the flower garden in summer, care should be taken to prevent their beginning to push previous to their removal to the open air, and this more especially if the trees are wintered in a dark-roofed house. Where such happens the young leaves have always a thin flabby appearance, and soon turn brown after the plants have been set out of doors; whereas, if growth is prevented until the trees are in the open air, the foliage will bear any amount of sunshine and still look green and healthy. Fuchsias are also a tribe of plants which must be looked to without delay where fine specimens are required. Shake the old plants out, reduce the roots, and repot them; then introduce them into the forcing-pit at a temperature of about 60°, and as soon as you can obtain cuttings an inch or two long strike these, and grow the plants on as quickly as possible, remembering that if you want large plants they must be grown to a considerable size before they show bloom. For soil use light, turfy, sandy loam, with turfy peat, half-decayed leaf mould, and some sand.

STOVE.

For the present place a few pots of the early-flowering Gesnera zebrina in the resting corner to ripen off gradually for early flowering again. Select a few Gloxinias and Achimenes in variety, shake them out, and pot the former in open turfy loam, heath soil, coarse charcoal, and sharp sand well incorporated, and do not pot too firmly. The Achimenes tubers should at first be placed in pans thickly, and potted singly as they push, in leaf mould and light loam in a very coarse open state, with a fourth of charcoal added. These two tribes of plants delight in a moderate bottom heat, and should by all means be started on bottom heat. See that no plant is suffering from want of water. If the green fly prevails smoke occasionally with tobacco, and see that no other kind of vermin is encouraged.—W. Keane.

DOINGS OF THE LAST WEEK.

Amusements on the Ice.—Cleaning and brushing ponds from snow for skating and other amusements formed a small portion of the work done. Like the rest of the community, our attention has been directed to the sad and fatal accidents that have taken place by the breaking of the ice this season, and as all contributions of experience may be useful in avoiding such evils for the future, we will merely mention a few of the results of a rather extended observation.

1st, Ice formed thinly on the surface of water, and considerably increased in thickness by the gradual melting and freezing of snow over the surface, is never so strong in proportion to its thickness as ice formed from water only.

2nd, When it is necessary to cut holes in ice, it should be at the farthest point possible from the place that curling, skating, and sliding are carried on.

3rd, We should object to cutting round the sides of ice, over deep water especially, as in its case we never knew an instance of ice rising, and leaving a space for air between itself and the water, although we have bored holes on purpose some scores of times; but in water so shallow as from 8 to 12 inches in depth, in severe frosts we have often found the ice rise in the centre considerably above the water, and especially if the reservoir was rather small. This we believed was partly owing to the resistance offered by the sides of the banks to the expansion of the ice. Such ice not resting on the water would not bear the weight that ice in contact with water would do, but, so far as we recollect, we know of no instance in which this rising took place in water from 3 to 6 or more feet in depth. We frequently have a rather sharp frost during the night, after a drizzling afternoon, and next morning many ruts on the road will present small planes of ice, even though there is no water left beneath them; but the ice in such cases is more brittle than that which is supported by water, and this slight circumstance confirms our observations on ice over large and deep reservoirs of water.

4th, When ice is to be treated for the amusement and the healthy exercise it will afford, the reservoir will be the most useful, and the most quickly frozen over, in proportion to its open exposure and shallowness—say from 12 to 18 inches in depth. This would not be a sufficient depth for water used for ornamental purposes, keeping waterfowl, &c., as well as for amusement; but in all public waters used for these two purposes, and where there are the means of letting off the water, the depth should be from 2½ feet at the sides to 4½ feet in the centre, where there should be a culvert, marked by posts, 2 feet deeper still; the whole bottom to be macadamised, or concreted; the mud when it has collected to be cleared away by the culvert; and then if the most venturesome receive a good drenching at times, there will be little likelihood of any loss of life.

KITCHEN GARDEN.

Here the most of the work has been attending to vegetables under protection, as Lettuces, Radishes, Endive, Asparagus, Sea-kale, Rhubarb, and Mushrooms, and trenching up some ground that had a little littery dung spread over it, as everywhere else was too hard for even a pick to enter. There was only a day or two in which such work could be done, as after the snow it would have been unsuitable, for turning in ground a little crusted at the surface is very different from turning snow down to the bottom of a trench. It would require more than a midsummer's sun to restore such ground to a genial warmth.

FRUIT GARDEN.

The weather being dry, we did much pruning in the orchard, opening the centre of trees and shortening the tops to bring the fruit more within reach. Treated differently a few trees of soft Codlin Apples, and, therefore, of no great value in the kitchen garden, meaning to remove them some day, and at present, to prevent their doing injury to the undercrops, pruned off the lower drooping branches. These trees generally produce heavily, but their fruit is but little cared for when more firm Apples can be obtained for sauce, pies, or puddings. The snow being light and dry, a good opportunity was presented, not only for pruning, but for carrying away all the cuttings whilst the ground was hard, and thus we have obtained a good

heap, or stack, which will be very useful for gardening purposes, lighting fires, &c. Daubed the cut parts with a paint of cowdung and clay.

The fall of snow afforded a second opportunity to give our orchard-houses a good smoking with bruised laurel leaves, and a repetition of the proceeding will be wholly unnecessary. The roof was so covered with snow that only a little smoke escaped next the wall at the top, and that was trifling. The snow became discoloured with the smoke, and retained a strong scent of the laurel leaves even when melting in heaps in front of the houses on the 23rd, when there was the commencement of a gentle thaw. Proceeded with washing the trees, well washing the wall with hot soap water, and then with limewash toned down with lampblack to take off the bright white of the lime. If we be as little troubled with insects as we were last season, we shall be quite satisfied.

Open Walls.—The weather prevented all work here except a little pruning on fine days; the snow hung on the trees pretty well until the 23rd, and that partly kept us from doing what we intended, namely, syringing the trees with warm water containing either a little salt in solution, or enough quicklime to give the trees and walls a coating. This we have long proved good for cleaning the trees and walls of moss, and preventing the attacks of many insects and snails, when followed by a sharp frost. If salt is used, no more should be employed than enough to make the water saline, say a handful of salt to five gallons, for if at all strong it will make the wall moist, and if the bricks or stones are old and soft, it will cause them to scale off and become softer and powdery. We had no quicklime at hand, or we would have contrived to have had this work done. It always proves most effective, even to loosening scale on the bark, if followed by a sharp frost. Warm water will be better than cold. Of course, when lime is used, the trees and wall will look whitish afterwards, but that is mostly concealed when the leaves open. If the colour is objected to, it may be darkened with a little soot.

Peach-house.—To keep the frost out from lots of plants, even the necessary little fire heat is beginning to have an effect on the trees, and, therefore, as we have no wish to hasten them on in such weather, we will remove forward Cinerarias at the first favourable opportunity. We removed as many young Pelargoniums, as would set two long shelves at liberty, and filled them with Strawberry plants from frames in the mild day or two between the frosts, filling the frames again in which there is just the mildest bottom heat. The few fruit of Black Prince Strawberry from a low pit were deficient in flavour, owing to the sunless weather, and plants in fine bloom have not set over-well from the same cause. We have no doubt they would have done better on shelves, in a steep-roofed house, where they could have had all the light which the season would have given them. Our Peach-house is at a pitch of about 45°, and there we have no trouble with Strawberries setting, but less or more trouble with early Strawberries in all houses, and especially pits, with low, flat roofs. A low house is better than a pit for this purpose, because containing according to its bulk more air, and because the light passes into the house past the Strawberry plants.

We have a lot of plants in a pit set on the top of a bed, near enough the glass, and where help from fire heat can be given them, and we expect if left there they will do tolerably well; but they will require more watching now than if they had been set on a stage, or boards, in the same pit, and we would not expect them then to do so well now, as if ranged on shelves in a house with a steep roof ranging from 45° to 35°. A couple of months after this the flat-roofed pit and frames will answer much better than now.

ORNAMENTAL DEPARTMENT.

The last charred and clay-burned heap was wheeled on the ground in the frosty mornings, and another heap nearly finished, that will clear up everything that can be so applied for the present. We hope after the 23rd, if the thaw fairly set in, to move a great many plants, and obtain more room for potting. In the meantime went on potting Fuchsias, &c., in soil warmed by standing in the Mushroom-house, over furnaces. Just as at this season it would be injudicious to supply water colder than the temperature in which the plants are growing, so nothing is so successful for covering plants with insects than fresh-potting them in soil much colder than that previously about their roots. In both cases, the water and the soil should be a few degrees warmer than the atmosphere in which the plants stood.

As respects the general management of plant-houses and pits see notices of previous weeks. The *watering* in such weather should be done in no careless manner. As a general rule, the above precept as to the water being quite as warm as the atmosphere, ought never to be departed from. The second great rule is, never to water a plant until it requires it, and then to give enough to reach every fibre, but not to run much through the pot, as, unless when the air wants moistening, in very severe weather the less water that is used the better.

It will often happen, even when the roots are damp enough, that plants will flag under a bright sun, when they have passed through a week or even a few days of close cloudy weather. Under such circumstances the whole processes of vitality were working in a most languid state, and, therefore, roots and leaves were acting in perfect harmony, but a bright sun breaks out suddenly, and the quickened activity of the leaves in evaporating cannot at once be met by the action of the roots, though moist enough, and flagging and signs of distress follow. The uninitiated at once pour water over the soil that was moist enough before, and which leaves it afterwards too moist, to be cooled inordinately by evaporation, and thus frequently pailful after pailful is used without quite redressing the evil, when a few quarts thrown as a sort of mist over the foliage would prevent all the mischief and most of the labour, and leave the soil in a more healthy condition. In a bright sun the leaves would soon dry, and, therefore, no danger would ensue from the foliage being left in a damp state at night. Such a slight syringing will most commonly be required during the forenoon. A slight shading would often answer equally well, but there is no remedy so quick, so refreshing, and so natural as a skiff from the syringe under such circumstances; and though it might injure some very tender plants with delicate foliage, it is very seldom that any harm will thus result to the generality of plants. When thus syringed in sunshine, there would be a little air in the house, and under such circumstances we have never realised among plants in general those evils of burning, spotting, and lens-blotching of leaves, which are so much enlarged upon as the consequence of the sun shining on damp foliage. Of course, we would not advocate this system to any great extent, and especially in summer, for then it would be less needed, as the changes from dullness to brightness are not so rapid as in winter and early spring; but there can be little doubt, when a bright day succeeds several of a dark dull character, that a skiff from the syringe will often be better for plants that rapidly perspire in sunshine than repeated drenchings at the roots when the soil is moist enough.

These, and the remarks of a visiting gardener, have reminded us of what is worth noting, as respects watering. In a large nursery establishment, a good many years ago, we were employed turning out a great many plants in rows, in a hot May. The plants were turned out, the trench about half filled, and firmed against the roots, and well watered, and then the dry earth was put over all, to prevent evaporation and yet secure plenty of moisture and coolness about the roots. The nurseryman on passing seemed pleased, asked us why we did the work so, and was satisfied—nay, more, said something very pleasing about thought and work going together. In a similar establishment lately, in an equally hot May, a young man had turned out Mignonette from pots into boxes, had packed them well, and watered them well from the spout of a pot; but as the sun was powerful, and the boxes stood in the sun preparatory to their being removed to a sunny verandah, the tops of the plants began to flag a little, and the young man was just giving them a whisk from the rose of a watering-pot, to refresh them, and check evaporation, when one of the firm passed, and ordered some one else to take the watering-pot from the young man, as he knew nothing at all about watering. Now, if the young man had intended to water the boxes in that way, the proprietor might have been right. As it was, inquiry into the subject would have shown that he would have found reason to praise, instead of to blame. Whoever again deluged the roots of such plants was only throwing water away. A very little on the foliage would arrest evaporation, and this was all that was wanted. But for the time it would take, watering from the rose is often better than watering from the spout, because the water from the rose takes so much more air along with it. Time, however, is an objection to such a mode in general cases, and, no doubt, the sweeping condemnation of the nurseryman was based upon it. The young man was actually attending in the best way to his employer's interests, when he received the reproof. A little inquiry would often save much unpleasantness, and the greatest and the wisest are only fallible at best.—R. F.

COVENT GARDEN MARKET.—January 30.

Improved supplies, and some difficulty in effecting clearances at former rates. French importations comprise Lettuces, Endive, Artichokes, young Carrots, Tomatoes, and Asparagus. Forced vegetables consist of Asparagus, Kidney Beans, Sea-kale, and Rhubarb. Potato trade very unsettled, good samples realising rather high rates.

TRADE CATALOGUES RECEIVED.

Carter & Co., 237, 238, and 261, High Holborn.—*Gardener's and Farmer's Trade-Mecum.* Part I.—*Flower Seeds, Plants, and Bulbs.* Part II.—*Vegetable and Agricultural Seeds.*

Barr & Sugden, 12, King Street, Covent Garden, London, W.C.—*Descriptive Priced List of Choice Seeds for Flower and Kitchen Garden.*

Butler, McCulloch, & Co., Covent Garden Market, London, W.C.—*Spring Catalogue of Seeds for the Kitchen Garden and Flower Garden.*

F. & A. Dickson & Sons, 106, Eastgate Street, and Upton Nurseries, Chester.—*Catalogue of Vegetable and Flower Seeds.*

Downie, Laird, & Laing, Stanstead Park, London, and West Coates and Pinkhill, Edinburgh.—*Catalogue of Garden, Flower, and Agricultural Seeds; Implements, &c.—Descriptive Catalogue of Roses—Descriptive List of French Hybrid Gladioli.*

Wheeler & Sons, Gloucester.—*Wheeler & Sons' Little Book, or Select Seed List.*

William Pontey, Huddersfield.—*Nursery List*, being a Catalogue of Forest and Ornamental Trees, Shrubs, &c.

Thomas Sampson, Preston Road, and Houndstone, Yeovil.—*Catalogue of Flower, Vegetable, and Agricultural Seeds.*

John Scott, Yeovil and Merriott Nurseries, Crewkerne, Somerset.—*Catalogue of Vegetable, Flower, and Agricultural Seeds.*

Robert M. Stark, York Road, Trinity, Edinburgh.—*Catalogue of American, Alpine, and Herbaceous Plants.*

Henry Cannell, Fuchsia Nursery, Station Road, Woolwich. *Select and Descriptive List of Fuchsias, Verbenas, Petunias, &c.*

Peter S. Robinson & Co., Trinity Nursery, and 33, St. Andrew Square, Edinburgh.—*Catalogue of Garden and Flower Seeds.*—*Catalogue of Forest Trees, Shrubs, Roses, &c.*

TO CORRESPONDENTS.

*** We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed *solely* to *The Editors of the Journal of Horticulture, &c., 171, Fleet Street, London, E.C.*

N.B.—Many questions must remain unanswered until next week.

Back Numbers (*G. B.*).—If you send us a list of the Numbers you require, we will let you know whether we can supply them.

Boiler for Heating Three Houses (*Weymouth*).—A cast-iron saddle boiler 30 inches long, 24 inches high, and 22 inches wide, will suit you. If you wished the middle house to be the hottest the boiler could be placed behind that, and the heat be taken to the other houses right and left. If the houses were intended to come in in succession from end to end, we would place the boiler at what was to be the earliest end, take a flow and return pipe all the length of the three houses, and from these have valves to admit circulation to the pipes of each separate house as wanted. If you wished to have early forcing in all three houses, averaging 20 feet by 11, then we would advise a boiler 6 inches longer.

Alkaline Manures for Potatoes.—*D., of Headcorn*, asks, "Has your correspondent 'D.,' of Deal, tried any of those alkaline manures recommended in February last by "W., *Ross, Herefordshire*," for growing mealy Potatoes? If he has, or any other correspondent, will he oblige, through the Journal, by stating the result of his trial, as the season for Potato planting is approaching?"

Plunging Material (*Novice*).—We could hardly say why the sand for plunging in did not answer, unless we knew more of the particulars. It ought to have answered over your tank if you have enough of heat. We presume your large slates are bedded on the tank, if so, no moisture will escape. In that case we would cover over with 6 inches of rough clean cinders, or clean small stones, and on that place finer ashes, sand, or cocoa-nut refuse, for plunging the pots in, with some upright pipes going through the sand or other material to the slate, for pouring water down when a moist heat was wanted, likewise for allowing the heat to rise into the atmosphere in which the cuttings are. If you use cocoa-nut refuse, do not let the bottom of the pot rest on much of it. If you use sawdust, lift the pot at times, or the bottom hole may become firmly fastened up, and see that no fungi grow. If you have plenty of heat nothing is more simple or cleanly than sand. It is difficult to make the heat pass through cocoa-nut fibre, especially when dry. Perhaps you did not have enough of top heat. We shall be glad to assist if we know more of your practice, the size of the bed and tank, the mode of covering the cuttings, the size of the house, the mode of giving top heat, and other particulars.

Propagating and Cucumber-house (*A Market Gardener*).—Your proposed arrangements will do either for propagating or Pines, but you will not have heat enough for early work. If your flue go along one side, you would require three pipes on the other side, two flows and a return, and we would prefer three pipes below the centre bed to two pipes. If these centre pipes were covered with 6 inches of clinkers or brickbats, placed as hollow as possible, and covered again with clean small stones, you could put your plunging material, either for cuttings or Pine plants, above. In the side walls opposite the hollow clinkers, &c., you could have five or six plugs on each side to let heat out, and let moisture in when you deemed it necessary. With this arrangement two pipes on the side might do. It would be as well if the centre bed were not more than 30 inches from the ground. You would need glass for many subjects in the propagating-bed. If you do not object to the glass division as to expense, it would be as well to divide the house into two, as you could regulate the treatment better as respects shading, air-giving, &c.

Vine Border Soil (*H. J.*).—The soil you enclosed, pared from the surface of an old meadow, is quite suitable, but should be mixed with some calcareous addition, such as bricklayers' limy rubbish and bones broken into small fragments.

Sowing Mistletoe Seed (*J. E. D.*).—Cut a triangle in the bark on the under side of a branch down to the wood, raise the point of the triangle, and insert the seed between the bark and the wood. No application or tying of any kind is needed.

Strawberry Plants Injured by Frost (*Fragaria*).—Strawberry plants in 32-sized pots that have stood out during the late severe frosts, and the roots of which seem all killed on the outside of the balls, had better be plunged as you propose, in a hotbed, plunging the pots to the rim to excite root-action, and keeping the lights off in mild weather. You must not give the plants more than 50° of bottom heat to commence with, increasing it to 70° gradually, and you must not think of forcing the tops until the roots are in action, in fact, you ought not to attempt to obtain from the plants very early Strawberries.

Grubs in Vine Border (*H. J. C.*).—We do not think that the grubs will injure the roots of your Vines. If you will state whether you require the Apples for dessert or kitchen use, and in what part of the British Islands you live, we will name some that may suit you.

Black Alicante Vine (*J. Bryan*).—Any Vine can be grafted upon any other variety of Vine, but what the effect a Bowood Muscat stock would have upon a Black Alicante grafted upon it we cannot tell. We do not know where tarpaulin can be purchased. If we wished to cover a Vine border, we should use Croggon's asphalt felt, which is much cheaper.

Pine Apples Black Inside (*C. H. A.*).—Atmospheric moisture when so excessive as to create drip has a tendency to cause the lower pips of the fruit to become discoloured and black, and even to decay before the upper pips are ripe; but we do not consider it will affect the interior of the fruit farther than the pips are discoloured and flavourless. Blackness at the centre of the fruit is caused by the soil being kept too wet. To combine at this season size with good colour and flavour requires great care in cultivation—in fact, large size can hardly be attained without sacrificing something, and we have now for some years been less particular about it in winter fruit, and have consequently kept the atmosphere and soil considerably drier, and have been rewarded with fruit—less in size certainly, but equal in flavour to those ripened under more favourable conditions. Maintain a moderate amount of moisture, and water carefully at the root until the fruit is ripening, then keep considerably drier.

Stocks for Camellias (*A Constant Reader, J. H. D.*).—We do not know where stocks for Camellias are to be had. You may graft by the plan known as whip-grafting, and then plunge the pots in the hotbed. You may obtain Camellia seed of any of the principal London seedsmen, and if you sow it the plants will be ready for grafting in two or three years, according to the encouragement given.

Horse Carrot (*Idem*).—The best Carrot for horses, at least that most valued by stablemen, is the Red Altringham, and for cattle the Yellow Belgian.

Heaviest Bunches of Grapes (*Dodger*). — We conclude that the Judges at Bury St. Edmunds will require the Grapes to be ripe.

PRIMULA SINENSIS SEEDLINGS (*D., Newark*).—The pips are fine, and of good substance, but there are very many of the same colour and quite equal to them. The specimens now produced are endless.

HALF-INCH BONES FOR VINE BORDER (*Vine Border*).—You may obtain the bones you require for a Vine border from the London Manure Company, 116, Fenchurch Street, London.

SOWING MELONS, COCKSCOMBS, AND BALSAMS (*Idem*).—For fruiting and blooming in July you should lose no time in preparing a hotbed for the Melons and Cockscombs, which should be sown in the first week in March. The Balsams may be sown in the first week in April.

HOTBED FOR CUTTINGS (*Fred*).—It will answer to dig out the soil, set the frame on the ground, and fill it inside with hot dung. The soil should be dug out to a depth of 2 feet 6 inches, and in filling with dung bring the latter up to the lights, shake it out evenly, and beat and tread it firm. Put on the lights, in a week or so level the surface, and if the dung has sunk much fill up the frame to within 6 inches of the glass, and cover with 3 inches of turfy loam two-thirds and one-third leaf mould. Sift the soil, place the siftings over the dung before putting in the finer portion, and over the soil spread an inch deep of sand. You may make the bed in the end of February, and put in the cuttings early in March.

STAFF REQUIRED FOR A GARDEN OF TWO ACRES, GLASS, &c. (*Oxonian*).—A garden of two acres, one-half kitchen garden and the other half pleasure grounds and flower garden, four thousand bedding plants, three Peach-houses, each 20 feet by 12 feet, a vinery, and two houses for other purposes, pits and frames 60 feet long, and a conservatory 50 feet by 14 feet, will require, to keep it in good order, and have everything in its proper season, a working head-gardener, an under-gardener, a strong youth of 18 or 20, and a labourer.

LYCASTE SKINNERI (*Edwin*).—The most likely cause of the short continuance of bloom is keeping the plants in an atmosphere much too warm. A temperature of from 40° to 45° is ample whilst the plants are in bloom. It is not necessary to give much water, but once since they began blooming is too little, especially if the atmosphere is dry and hot. In a greenhouse or room they require very little moisture, whilst in a stove more is needed. Water more frequently. We cannot name florists' varieties of Azaleas, and, besides, your flowers were all smashed.

EXAMINATION OF GARDENERS (*Idem*).—Apply to Capt. Cockerell, Assistant Secretary, Royal Horticultural Society, South Kensington, W., stating what you wish, and he will furnish the requisite information.

VINE BORDER (*Charles*).—We should have liked the border better if it had been wider than 7 feet, but it will serve the Vines for many years if the roots be nourished by frequent top-dressings of rich compost. We would advise you to make a border on the outside of the house equal in width to that on the inside, and let the roots pass into the former through arches or apertures in the front wall. Plant the Vines inside, and confine the roots to the inside border for three years, then make the outside border.

GESNERA ZEBRINA SPLENDENS LEAVES CURLING (*Idem*).—The evil arises from an insufficient amount of heat and moisture in the atmosphere. Give the plants more heat and atmospheric moisture, and avoid wetting the leaves, and you will find that these will not curl. They do so naturally when they are becoming mature. Avoid cold currents of air.

PRUNING VINES (*D. W.*).—You have deferred pruning too long. It should be performed immediately, or soon after the leaves fall Prune to the third eye as you propose; but, the canes being well ripened, we should cut them in to two good sound eyes, or one, not counting the two embryo eyes at the base of each shoot, which is what we presume you mean by cutting at the third eye. One good plump eye is ample, and to that we would prune, not counting the embryo eyes at the base of the shoot. Your plan of allowing one shoot to bear fruit and another to grow for wood on the same spur is not good. It crowds the bearing-shoot too much, and impoverishes the border.

HARDINESS OF PEACH TREES (*Idem*).—The late severe weather has not injured the wood of our trees on walls, and it will not injure the wood of those in houses unless the buds have begun to swell and are on the point of expanding, and then not the wood of last year, but the present year's growth. A little fire during the late severe weather to keep out frost would not do any harm.

STRIKING VERBENA CUTTINGS (*Cestria*).—1, The pans or pots should be well drained, and, a little moss or cocoa-nut fibre having been placed over the drainage, filled to within an inch of the rim with turfy loam, leaf mould, and sand in equal parts; then fill to the top with silver sand so as to present a slightly rounded surface, but if silver sand cannot be obtained, river sand will do if not too sharp. 2, They strike best in a bottom heat of from 70° to 75°, and a top heat of from 65° to 75°. The atmosphere should be moist.

SPROUTING POTATOES FOR PLANTING (*M. J. E.*).—Your Ashleaf Kidney should be taken out of the "pies," weather permitting, early in February, and be placed in the boxes, eyes upwards, and it is best to place them only one layer thick. A box will hold a large number set on their ends. The boxes may be put in the chamber you mention, and an old sheet or similar light covering will be sufficient, but you may, if there is any likelihood of the Potatoes being frozen, cover them with straw. You must examine them frequently, and when the sprouts are half an inch long remove the covering, and harden them off by giving abundance of air before planting. If this is not done the sprouts are liable to be broken off in planting. The third week in March is a good time to plant them if the weather be favourable, and from that time to the first week in April. The Ashleaf Kidney is as good a Potato as any for a first early. Royal Ashleaf is a little better cropper, but is not so early by ten days or a fortnight.

FERNERY (*E. M.*).—We think your arrangements good. The flue carried along the front and one end will, if above ground and not covered by rockwork, be sufficient to keep out frost, and, indeed, maintain any temperature desired, and as you do not wish for Ferns that require a high temperature, a fine will serve you more economically than hot-water pipes. You may use Hartley's rough plate glass ⅛-inch thick. The height in front is too low, there should be 3 feet of wall and 3 feet of glass, so that you will have a door 6 feet high, and it should be 3 feet wide. The roof will have ample fall, if the front be 6 feet high. For so narrow and small a house it will be sufficient to have two ventilators in the back wall, each 2 feet long and 15 inches wide. All the lights may fixed, which will lessen the expense. We think the house will answer well. It will require shading from March to October.

PRIMULAS (*Richard Dean*).—The seedling Primulas you have submitted to us are charming things. Large, beautifully fringed, and richly coloured, they cannot fail to be valuable acquisitions. Of those which we particularly remarked, the most striking were *Splendens grandiflora*, a splendid flower of dark magenta crimson, and *Beauty*, a blush, feathered and suffused with deep pink, and with a deep yellow centre. Some are very beautifully flaked like Carnations, while others are spotted and freckled with colours darker than the grounds. We congratulate you on the possession of such a stock.

POTATOES.—"*A. B.*" wishes to be informed if Dawe's Matchless Kidney is the same as Webb's Imperial; also, is the Cheshire Early Pink Eye the same as that known in the north as the Early Pink Eye Kemp?

PEACH TREES IN ORCHARD-HOUSE (*R. W., Bristol*).—Continue to keep your house cool. The slower the buds are developed the more likely you are to have a good crop.

PASTURE GRASSES FOR AUSTRALIA (*C. S.*).—There are as many climates in Australia as there are in Asia. You should have mentioned the part of Australia. If not in the extreme north of that land any of our pasture Grasses will probably succeed as well as they do on similar soils in England.

SELECT CARNATIONS AND PICOTEES (*W. W.*).—*Carnations:* Admiral Curzon, Lord Rancliffe, Black Diamond, Lord Milton, Fanny, Sarah Payne, Premier, Squire Meynell, Firebrand, Sportsman, Ariel, and Friar Lawrence. *Picotees:* Mrs. Norman, Isabella, Amy Robsart, Lord Nelson, Mrs. Dodwell, Robin Hood, Mrs. May, Finis, Mrs. Barnard, Venus, Bertha, and Mrs. Fisher. These would cost from 2*s.* to 2*s.* 6*d* per pair. Any respectable florist could supply them or procure them for you. We cannot recommend dealers.

NAMES OF PLANTS (*J. C. S.*).—1 and 2, barren and fertile fronds of the same Fern—Cystopteris dentata; 3, Polystichum aculeatum, a small frond.

METEOROLOGICAL OBSERVATIONS in the Suburbs of London for the Week ending January 29th.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

POULTRY JUDGING.

IT appears that we cannot have a standard of excellence to guide us as to what birds are fit for competition. I would propose that each of our Judges should publish what he considers to be the standard of excellence in respect to Game and Game Bantams, as each arbitrator differs in opinion with respect to the classes. For instance, I took second and third prizes at our largest exhibition, and exhibited the same fowls again at one of our smaller shows, but in better condition, but did not receive even a commendation. How was it? I ask. Simply because they were judged by another arbitrator. I am really at a loss to know how to select my fowls for competition. I think you will coincide with me, that we want some definite information to guide the judges as well as us breeders.—A SUFFERER.

[Many alterations are desirable in poultry judging, but much

more forbearance is desirable on the part of losing exhibitors. They are naturally prone to magnify the merits of their own birds, and to diminish the merits of their conquerors. The birds of "A Sufferer" may have been excellent, but those which took the prizes may have been more excellent in the estimation of unbiased judges. As to the requisite points in all varieties of poultry, they are well known, and the duty devolving upon a judge is to estimate correctly the preponderance of excellence in all the points in each pen. Now, practice greatly facilitates this estimating, and, if for this reason alone, we wish that not more than half a score judges were selected, and that they were exclusively employed, the selection from them being left to the committee of the show. No suggestion was ever more fraught with dissatisfaction than that which recommends an increased number of judges, the increase being taken from local sources. Such an increase, without adding to the ability employed, would inevitably add to the risk of favouritism.—Eds.]

CHARACTERISTICS of the PRINCIPAL SORTS OF GAME FOWLS.

(*Continued from Vol. XI., page* 436.)

The sorts with the hen-tailed cocks have some of them been very celebrated in the north country for their fighting qualities. These birds are small in size, but very hard in flesh, and short in body; they were celebrated for their hard fighting and activity, and were quite equal to the best fowls in their fighting properties. They were of various colours—Polecats, Spangles, Piled, Partridge, Cinnamons, Furnaces, and other colours. They are now, I believe, very rarely if ever found.

Dark Greys, Brown Reds, and Cheshire Piles are the best and sharpest three sorts for fighting, the first two being also the two hardest sorts of all. Some of the Red-breasted Ginger Reds are quite as good as these three sorts, especially an East Suffolk breed of Ginger Reds, of which the cock birds are very red, and which I will describe a little as I go on with the other sorts in rotation.

I will now mention some of the least common sorts.

Polecats and Spangles are sometimes good birds. Cuckoos are not good in general. The Red Furnaces are marked with large fire-coloured patches on a white ground, and are quick and good in general. Mealy Greys are often good. Dark Birchens are too much mixed in blood to be a sportsman's bird, though often very good. Yellow Birchens are not good in general, though some strains are so. Blue Duns with yellow eyes and legs are the worst of all, being the softest and weakest of all Game fowls. White Game fowls are good and quick, and fight well when red-eyed and white-legged; when yellow-eyed they are not good birds. They are not used for fighting, though resembling the Piles in their qualifications. Black Game fowls are both slow and soft, perhaps slower than any Game fowls. The Brassy-winged Black cocks are the best cocks of this colour. The Furnace breed of Blacks are yellow-backed, and as good as any Blacks, but now quite rare.

Black-breasted cocks and Dun-breasted cocks are in general slower than all other colours, but when with red eyes they are good. No high-bred Game fowls have any other than black or red eyes. The yellow or daw-eyed Blacks are very inferior birds. Yellow-eyed Red Duns are also inferior birds.

Before mentioning the rest of the more common sorts, I will name the counties producing the best Game fowls; these are the northern and the midland counties, especially the latter:—

1. Lancashire.—The best Brown Reds, all others good.
2. Yorkshire.—Good Reds and Greys of both sorts.
3. Staffordshire.—Good Reds and Greys of both sorts.
4. Cheshire.—Best Piles, good Whites and Duckwings.
5. Warwickshire.—Black-breasted Reds and Brown Reds.
6. Shropshire.—Reds, Greys, Birchens, and Blacks.
7. Nottinghamshire.—Black-breasted Reds and Duckwings.
8. Lincolnshire.—Black-breasted Reds, Birchens, and Blacks.
9. Derbyshire.—Good Piles, Brown Reds, and Gingers.
10. Leicestershire.—Good Piles, Whites, and others.
11. Worcestershire.—Black-breasted Reds and Duckwings.

The southern counties have rather inferior birds, except London and its vicinity. Wales, Scotland, and Ireland have some good birds, Wales more especially so. Lancashire and Cheshire on the whole breed the best birds, as being lighter-fleshed and more active in general than any others. Birmingham and its vicinity is celebrated for its Game fowls, and Manchester for its Brown Reds; Chester for the best Piles in England. Newmarket was once very celebrated for its Game fowls, but is not so now. The four southern counties had the best Red Duns; and Cumberland and Westmoreland breed most Blue Duns, I have heard, though this colour is certainly rare, as are Red Duns now.

I have been acquainted with Game fowls since the year 1831, when a boy of eleven years old, and therefore have had experience enough to be able to give a correct opinion on all matters relating to them. The Lancashire Brown Reds have carried off more silver cups at exhibitions during the last six years than any other Game fowls. At all the early exhibitions the willow-legged Black-breasted Reds took nearly all the silver cups for the first few years.—Newmarket.

(To be continued.)

PROTRACTED DETENTION OF POULTRY AT EXHIBITIONS.

May I be permitted through your Journal to entreat the secretaries of poultry shows to be more particular in fixing the days for their exhibitions? Take Manchester for example—for a three-days show to the public, my birds had to leave home on Wednesday morning, December 19th, and were not returned till Wednesday night the 26th, an absence of eight days! I cannot learn when they were sent off on their return tourney, but being Christmas week they had been detained, jossed about, and starved, till they were more dead than alive; far too ill to eat, and had to be fed by hand for some days. Their plumage was broken and spoiled, and up to this time (January 11th), they are still suffering from the effects of the exhibition. I believe they had every attention at the Show, but why keep our pets confined in their pens over a Sunday, which is constantly arranged, and in this case over Christmas day as well? My poultry man said, "The birds are more knocked up from this Show than they have ever been before."—Exhibitor.

WANT OF COURTESY AND LIBERALITY.

I wrote on the 1st of January begging the Secretary of the Bristol Poultry Show to send me a catalogue; on the 4th I had not received one. The judging was completed at 2 P.M. on the 2nd. This was a peculiar hardship, as I was thus forced to make my entries for Walsall without knowing my birds' fate at Bristol, and I happened to be particularly anxious as to the judgment on a certain pen at Bristol, with a view to finding out whether that pen would be worth entering for Walsall or not. Also, I wrote and asked the Secretary for a ticket of admission to Bristol Show. He refused, though I exhibited nine pens. Can illiberality go much further?—An Exhibitor.

MUTILATING POULTRY AT EXHIBITIONS.

I saw in a recent Number of your valuable Journal a complaint by "An Exhibitor," who had the misfortune to have a bird spoiled, either in its transit to or at the late Exhibition held at Manchester. I sent two pens of fowls to the late Leeds Exhibition, and on their return I found both the cock birds minus a sickle feather; I examined the hampers, but neither of the feathers was in them. A worse case than this has come under my notice—that of a pen of Silver-spangled chickens. They were sent in perfect condition to the same Exhibition (Leeds), and on inspection on their return, one of the pullets was found to have lost every laced feather from both its wings. I will leave it to other exhibitors of more experience than myself to say if it was possible to strip the pullet of its lacing accidentally. Such cases as the above are becoming quite common. It is very galling to see birds in such a condition after so much labour has been spent upon them.—Thos. Wrigley, jun., *Tonge, Middleton, near Manchester.*

EXHIBITING BORROWED FOWLS.

Is this dishonest practice really carried out in the way alluded to by "Exhibitor?" Surely the best reply is publicity. Will "Exhibitor," as he knows several cases, mention the names? I was applied to once or twice some years ago, possibly by a member of the lending fraternity, as my warm reply seems to have put all such proposals at rest. There can

be no question to every straightforward mind that the practice is most dishonest. It is not only, as in your note to "Exhibitor's" letter, obtaining money under false pretences, but it is a robbery of the honour that but for the borrowed birds would go to other pens.—Y. B. A. Z.

POULTRY IN CONFINED SPACE.

In a Letter Box notice in the Journal of December 4th, Mr. J. R. Beyton asks if my eight hens have any run attached to my house 12 feet by 6. To this I reply, None whatever. The open part is partly paved, and partly covered with gravel, drift-sand, and mortar rubbish; and they have a dust bath, about 18 inches square, covered so as to prevent its becoming wet. I give them green food whenever I can obtain it.—S. G. J.

BRAHMA POOTRAS AT THE BRISTOL SHOW

In my "Dottings" at Bristol I endeavoured to give my own impressions without favour or personal bias one way or the other. Many may differ from those remarks, and every one has a right to his own opinion. I never meant to make remarks unkindly or unfairly, and I confess myself somewhat surprised at the tone of Mr. Wright's reply.

I do not consider that "I virtually questioned the decision." To the best of my recollection, and I write from recollection, I said that the chicken class generally of Dark Brahmas was inferior. The Judges, I think, agreed with me, for in a large class they gave no commendation beyond the prize pens. Then I said that Mr. Wright's pen was poorly feathered. This is just a matter of opinion—*I* consider the birds very decidedly so. Mr. Wright does not. Well, we simply differ in what we deem heavy feathering; but I think if any impartial person examined the feathering in this pen and that of Mr. Boyle's single Brahma cock he would consider Mr. Wright's birds poorly feathered; at any rate, I must adhere to my own idea about them. As regards Mr. Boyle's second-prize pen, the breasts of the pullets certainly did not match.

Mr. Wright then praises Messrs. Hewitt and Douglas as "eminent judges." In this I perfectly coincide with him, and I am quite willing to abide by their opinion of the moderate vulture hock, as evidenced by their decisions in the Cochin classes. I have stated in my "Dottings" that Mr. Cattell's Cochin cock was too much so, even to please me! Whether my adherence to moderate vulture hock has "nearly ruined my own yard and some others crossed from it," I cannot say. My chickens of 1866 were not often exhibited, but in every case where they were shown as chickens they obtained notice. This does not look like "ruin" to my own yard; and as regards "others crossed from it," I happened to see the yards of one person last year who, two or three years back, crossed extensively from my yard. I admired his pullets exceedingly, and I have heard Mr. Wright say how much he admired them. The gentleman's reply to my admiration was to the effect that he owed it to me. So much for the ruin of other yards!

Lastly, Mr. Wright says, "'Y. B. A. Z.' had made several entries, and it was a subject of general inquiry why he did not send his birds." Surely the anxiety on this point was jocular. Mr. Wright knows quite enough of Brahmas to be convinced that no "perfect pen" was likely to be exhibited at the price (£2), at which my pens were entered in the old and chicken classes, and if he and others really wish to know why I did not send them, I reply, I had sold the cockerel from one pen, and one of the hens from the other. His last paragraph on my pens runs thus —"A single cock he did send, but the bird had the misfortune to remain unnoticed." Well, I am free to confess that I considered this unnoticed bird deserved the second prize, and I will go further and say that I would not exchange him for any other bird in the class save the first-prize bird. I am so tied to work that I have not the opportunities Mr. Wright enjoys of seeing other birds and comparing mine with them. During 1866 I never attended a single show, and I willingly allow that this poudering over one's own stock alone is disadvantageous; but this is my misfortune, not my fault. Had I seen my single cock bird in a pen before, he would not have been sent to Bristol. He does not show himself off, and is cowed—in fact, he is frightened; under such circumstances no bird can look well, yet he was certainly the shortest-legged bird in the class, and of very good colour. Mr. Wright does not add of this "unnoticed" bird, that when he saw him in my yard a few weeks before he admired him exceedingly, and would willingly have purchased him if I had been so disposed, in spite of the "ruin" that my stock seems to produce. I must also add that, as I understood Mr. Wright, he paid me the compliment of saying that he preferred my cocks to those of Mr. Boyle, and that he should like to breed from Mr. Boyle's pulleta and the identical "unnoticed" Bristol bird!—Y. B. A. Z.

WALSALL POULTRY AND PIGEON EXHIBITION.

It is but rarely we have to record such an extraordinary amount of success as that which attended the second Show held under the auspices of the local Committee of Walsall, on the 26th, 28th, and 29th inst. Nothing has been omitted that possibly could be done to secure success to the undertaking, and the whole of the Committee have worked together most harmoniously. Where such is the case success is almost certain, more especially, as in the case of Walsall, when everything is carried out fairly, openly, and aboveboard. There are committees, though few, to whom the experience of the Walsall management might prove a benefit, for they not only candidly acknowledged on the printed catalogues who were the Patrons, &c., of the Exhibition, but also the names of the Committee themselves; and to this, no doubt, could easily be traced public confidence as regards the individuals responsible for the payment of the very liberal prizes offered. In this case, however, where all was so fairly laid open to the inspection of the public, but little hesitation could exist, for the Committee determined to carry out to the very letter the arrangements as organised. The whole of the prizes were paid on the spot to any party identified at the Show as a winner, and the remainder of the prize money was sent to absentees through the Secretary of the Show as soon as possible. The cups were of sterling silver—could not some few committees take warning from the last two words?—and these were reserved for public inspection until the close of the Show, to be then at once remitted to the successful persons who through so severe a competition had merited and secured them. They cost the Committee every farthing nett cash of the wholesale price affixed to them; and we may with confidence add, many times have we seen cups of reputedly some two or three sovereigns' additional value given as prizes, of but little if any better than one-half the value of the Walsall cups, whether considered as to their intrinsic or artistic worth. We have only to add our earnest hope that for very many years the successful may enjoy the use of these most ornamental appendages to their social boards; and that even when they themselves are numbered among the past, these cups may still remain evidences of the energy and the success of the winners.

A short remark or two may here be made as to the principle carried out in respect to the catalogues and prize lists of the Walsall Show:—The names of all parties responsible either for the payment of the prizes or the appointment of them were made known. The result was, that at a second show only, 836 pens were brought together, representing almost every principal breeder's yard, not only in our own country, but even in the Sister Isle. It is evident, therefore, that openness and straightforwardness of conduct in poultry shows secures public confidence, whilst the contrary invariably causes distrust and dissatisfaction.

From the absence of the birds of several of our principal Dorking breeders, owing to the injury done to the health of their respective yards by the late severe weather, the *Dorkings* were not so good as might be supposed from the entries, as frost-bitten birds were general. Still, although we regretted to find many first-rate pens, though entered here, could not be sent, the class was generally good. The *Spanish* were first-rate, and an entry of forty-three pens in this class, with only a pen or two not present, proves winning in this branch was not an easy matter. The pens of every principal breeder were present, and the deteriorated condition of not a few pens was attributable exclusively to over-frequent exhibition, a feature now likely to be withdrawn on account of the nearly-closed exhibition season. This is so far well, as birds brought down to a very low standard by excessive exhibition in the first months of the year, rarely breed well during the subsequent season. *Cochins* were first-rate, and, perhaps, there was not a single pen in the whole Exhibition more deserving of special distinction than the winning Partridge-coloured ones. The hen in this pen was certainly fairly worth a journey of many miles to look upon, being perfection. Buff Cochins were all good; those constituting the second-prize pen were, as stated by the Judge, decidedly the best in the class but for the severely frost-bitten comb of the cock. From inquiry we find the owner, who as an old exhibitor we have hitherto given credit for being more experienced in such casualties, placed, after washing for the Walsall Show, the old cock near the fire to dry, with strict directions "to see that he did not become overheated." His subordinate, promising strict obedience, first took possession of the post of trust, lighted his pipe immediately after his employer's back was turned, and at length woke up to find to his own annoyance the cock's comb blistered from the sudden application of heat, and his master angry at such a neglect of duty. We may here mention, as our own anxious desire is to forewarn all other exhibitors, that in all cases of frost-bite, snow, snow water, or the coldest pump water, is the best application to restore vitality. Fire-warmth is the most dangerous of all applications, and should not in any case be resorted to. *Brahmas*

were very good, Mr. Boyle, of Dublin, being the cup-winner. Mr. Fletcher, of Manchester, took both first and second prizes in all the *Game* classes, with birds most unexceptionable in carriage, colour, and last, though not least, condition. *Hamburghs* were capital. In these classes, as in many other varieties, two hens were occasionally sent instead of one, as stipulated by the Walsall prize schedule. It really appears as though some of our readers pay little attention to the requirements of each particular show, though we have mentioned so particularly and so often that non-compliance with these is a fatal objection. The proper number of hens, one or more, must be sent; a hen too few, or one too many, is a "disqualification." The *Bantams*, *Turkeys*, the Fancy varieties of *Ducks*, and the Selling classes were uniformly excellent. The attendance of visitors was very good.

Dorkings (Any colour).—First and Fourth, T. Tatham, Kingsthorpe, Northampton. Second, J. D. Hewson, M.D., Stafford. Third, Hon. Mrs. D. Pennant, Penrhyn Castle, Bangor. Highly Commended, Mrs. Arkwright, Derby; J. K. Fowler, Aylesbury. Commended, H. Savile, Rufford Abbey, Nottinghamshire.

Spanish.—First, H. Lane, Bristol. Second, A. Heath, Calne. Third, J. R. Rodbard, Aldwick Court, Wrington, Bristol. Fourth, Messrs. Burch and Boulter, Sheffield. Highly Commended, E. T. Holden, Walsall; A. O. Worthington, Burton-on-Trent; J. Walker, Wolverhampton; J. R. Rodbard; N. Cook, Chowbent, Manchester; J. Hildick, Walsall. Commended, A. O. Worthington; E. T. Holden; G. Lamb, Compton, Wolverhampton; A. Heath; Hon Miss D. Pennant; J. Walker; J. Clews, Walsall; J. Thresh, Bradford.

Cochin-China (Partridge).—First and Second, J. Stephens, Walsall. Third, T. Stretch, Ormskirk. Highly Commended, A. Fenton, Rochdale; E. Tudman, Ash Grove, Whitchurch. Commended, J. Stephens.

Cochin-China (Buff or Cinnamon).—First, R. White, Sheffield. Second, H. Tomlinson, Balsall Heath Road, Birmingham. Third, H. Mapplebeck, Woodfield, Moseley, Birmingham. Fourth, W. Bayliss, Walsall. Highly Commended, W. A. Taylor, Manchester; Hon. Miss D. Pennant; H. Mapplebeck; D. Cunningham, Statfold Hall Farm, Tamworth; A. Fenton. Commended, H. Warner, Loughborough.

Cochin-China (White).—First, Capt. D. Lane, Great Barr Hall, near Walsall. Second, F. W. Zurhorst, Donnybrook, Dublin. Third, A. O. Worthington. Commended, Rev. W. J. Mellor, Colwick Rectory, near Nottingham; E. C. Boville, Willington, Burton-on-Trent.

Brahmas.—First, R. W. Boyle, Bray, Co. Wicklow, Ireland. Second, Col. Stuart Wortley, Grove End Road, London. Third, H. Lacy, Hebden Bridge. Highly Commended, J. Stephens; J. H. Cuff, Metropolitan Cattle Market; G. H. Roberts, Preston; H. Lacy; H. M. Maynard, Ryde, I.W.; J. H. Hinton, Hinton, near Bath. Commended, Rev. W. J. Mellor, Nottingham.

Game (Black-breasted and other Reds).—First and Second, J. Fletcher, Stonecclough, near Manchester. Third, C. W. Brierley, Middleton, near Manchester. Commended, S. Matthews, Stowmarket; W. Wainwright, Stretton-under-Fosse; J. Tyler, Loughborough; C. Minors, Sudbury; S. Dnpe, Evercreech.

Game (Any other colour).—First and Second, J. Fletcher (Duckwings and Piles). Third, S. Matthew. Highly Commended, J. H. Williams, Springbank, Welshpool (Duckwings). Commended, A. K. Briggs, Rawden; T. Robson, Penkridge.

Hamburghs (Golden-pencilled).—First and Second, T. Wrigley, jun., Tonge, Middleton. Third, F. Pittis, jun., Newport, I.W. Highly Commended, F. D. Mort, Stafford; F. Pittis, jun. Commended, W. Meanley, Birmingham; T. Amphlet, Walsall; A. K. Briggs; T. Walker, jun., Denton.

Hamburghs (Silver-pencilled).—First and Second, H. Pickles, Earby, near Skipton. Third, T. Sharples, Rawtenstall. Highly Commended, J. Preston, Allerton.

Hamburghs (Golden-spangled).—First and Third, J. Ogden, Hollinwood, Manchester. Second, T. Walker, jun. Highly Commended, A. K. Wood, Castle Donnington; I. Davies, Harborne; Messrs. S. & R. Ashton, Mottram, near Manchester; T. Fletcher; C. W. Brierley. Commended, H. E. Emberlin; W. Beetlestone, Walsall.

Hamburghs (Silver-spangled).—First, A. K. Wood. Second, J. Fielding, Newchurch, near Manchester. Third, T. Fletcher. Highly Commended, J. M. Kilvert, Ludlow; W. Horton, Albrighton; J. A. Taylor, Manchester; J. Fielding; Hon. H. W. Fitzwilliam, Wentworth-Woodhouse; A. L. Aspinall, Taynton, near Gloucester; J. Jackson, Bury, Lancashire.

Game Bantams (Black-breasted and other Reds).—First, H. Shumach, onthwell. Second, J. W. Morris, Rochdale. Third, F. Pittis, jun. Highly Commended, Master G. Crosland, Wakefield; A. Cottam, Easthorpe; C. W. Brierley; A. Fenton.

Game Bantams (Any other colour).—First and Second, F. Pittis, jun. (Duckwings). Third, H. Shumach (Duckwings). Highly Commended, Master G. Crosland (Duckwings).

Bantams (Gold and Silver-laced).—First and Second, M. Leno, Markyate Street, near Dunstable. Highly Commended, T. C. Harrison, Hull.

Bantams (Any other variety).—Cup and First, W. J. Cope, Barnsley (Pekin). Second, H. C. Woodcock, Leicester (White Japanese). Third, E. Cambridge, Bristol (Black). Highly Commended, S. S. Mossop, Long Sutton (Cochin); H. Draycott, Humberstone. Commended, T. Boucher, Birmingham (Japanese); J. R. Jessop, Hull (Black); H. C. Woodcock (Japanese); T. Gameson, Walsall (Cuckoo).

Any Variety not Named.—First, S. A. Wylie, East Moulsey (La Flèche). Second, J. Percivall, Harborne, near Birmingham (Poland). Third, National Poultry Company, Bromley, Kent (Gueldres). Fourth, T. Fletcher (Black Hamburgh). Highly Commended, M. York, Pelsall (Manx); Col Stuart Wortley (Crève Cœur); National Poultry Company (Crève Cœur). Commended, National Company (La Flèche); Col. Stuart Wortley (Crève Cœur); Miss M. E. Lamb (Negroes); R. H. Nicholas, Malpas, near Newport (Andalusians).

Ducks (Aylesbury).—First, H. Jones, Aylesbury. Second, J. K. Fowler, Aylesbury. Third, E. Leech, Rochdale. Highly Commended, H. Jones.

Ducks (Any other variety).—First, T. C. Harrison (Mandarins). Second, C. W. Brierley (Shell). Third, H. Savile (Carolinas). Highly Commended, Miss H. Walker, North Wales (Rouen). Commended, J. E. Bealey, Bloxwick (Wild); A. Fenton; Capt. D. Lane (White).

Geese.—First and Second, J. Lycett, Stafford. Third, J. K. Fowler. Highly Commended, A. O. Worthington; H. Savile; Hon. H. W. Fitzwilliam.

Turkeys.—First, E. Leech. Second, D. Cunninghame. Third, F. E. Richardson Uttoxeter. Highly Commended, A. O. Worthington. Commended, F. E. Richardson.

Selling Class.—First, T. Tatham (Dorkings). Second, Hon. Miss D. Penuent, Penrhyn Castle, Bangor (Brahmas). Extra Second, S. & R. Ashton. Third, National Poultry Company (Crève Cœurs). Extra Third, J. M. Kilvert (Hamburghs). Fourth, J. Preston. Extra Fourth, C. W. Brierley. Highly Commended, Mrs. Williamson, Leicester Cochins); H. & S. Cooper, Walsall (Spanish); H. E. Emberlin, Leicester (Bantams; G. H. Roberts (Brahmas); T. Amphlet (Spanish); H. Savile (Polands); C. Barber, Walsall (Spanish); F. W. Earle, Edenhurst (Ducks); J. Wright, Melton Mowbray (Hamburghs); J. D. Hewson (Dorkings); M. Brooksbank, Manchester (Brahmas). Commended, J. H. Williams (Game); R. H. Nicholas (Hamburghs); H. E. Emberlin (Hamburghs); W. Bayliss (Cochins).

PIGEONS.

Carriers.—*Cock.*—First, R. Fulton, Deptford. Second, W. Siddons and Sons, Birmingham. Very Highly Commended, F. Crossley, Elland, Yorkshire. Commended, S. A. Taylor, Sutton Coldfield; H. Yardley. *Hen.*—First and Second, F. Crossley. Very Highly Commended, R. Fulton; W. Siddons & Sons. Highly Commended, W. Siddons & Sons.

Powters.—*Cock.*—First, F. Crossley. Second, J. Hawley, Bingley. Very Highly Commended, A. Heath, Calne, Wiltshire; C. Bulpin, Bridgewater; A. H. Stewart, Harborne, near Birmingham; J. E. Breward, Coventry; R. Dodge, Sheffield. Commended, R. Fulton. *Hen.*—First, A. H. Stewart. Second, A. Heath. Very Highly Commended, J. Hawley. Highly Commended, R. Fulton. Commended, J. Hawley.

Tumblers (Almond).—First, J. Ford, Monkwell Street, London. Second, R. Fulton.

Tumblers (Any other variety).—First, R. Fulton. Second, F. Crossley. Very Highly Commended, C. Bulpin. Commended, J. Fielding, jun.

Jacobins.—First and Second, R. Fulton. Highly Commended, F. Else, Bayswater. Commendad, C. Bulpin.

Fantails.—First, F. Else. Second, H. Yardley. Very Highly Commended, H. E. Emberlin. Highly Commended, R. Dodge.

Antwerps.—First, S. A. Taylor. Second, Master G. Crosland. Highly Commended, J. Hawley; S. A. Taylor. Commended, J. Hawley.

Trumpeters.—First, J. R. Jessop. Second, J. Hawley. Commended, W. H. C. Oates, Newark; Rev. W. J. Mellor.

Owls.—First, F. Crossley. Second, J. Fielding, jun. Very Highly Commended, F. Crossley. Commended, J. Fielding, jun.

Barbs — First and Second, F. Crossley. Highly Commended, H. Yardley. Commended, H. Yardley; J. Fielding, jun.

Nuns.—First and Second, C. Bulpin. Commended, F. Else.

Turbits.—First, R. Siddall, Sheffield. Second, H. Mapplebeck. Very Highly Commended, H. Yardley. Highly Commended, C. Bulpin; F. Crossley.

Dragons.—First, F. Crossley. Second, J. W. Ludlow, Birmingham. Highly Commended, J. W. Ludlow. Commended, H. Yardley; C. Bulpin.

Any other Variety.—First, H. Yardley, Birmingham. Second, National Poultry Company (Priests). Very Highly Commended, S. A. Wyllie (Runts). Highly Commended, H. Yardley. Commended, National Poultry Company (Runts); A. H. Stewart (Siberian Ice); H. Yardley; J. Hawley (Swiss); F. Crossley (Swallows); C. Bulpin.

Selling Class.—First, H. Yardley. Second, A. H. Stewart (Jacobins). Third, J. Walker, Newark. Highly Commended, J. Percivall (Isabels). Commended, R. Dodge (Powters); J. Hawley; H. Yardley.

Silver Cup for the best collection of Pigeons, F. Crossley.

Mr. Edward Hewitt, of Birmingham, judged the first twelve classes of Poultry, Mr. Tegetmeier, of London, the remaining Poultry classes, and Mr. Cottle, of Cheltenham, the Pigeons.

PERTH POULTRY SHOW.

This was held in the City Hall, Perth, on the 24th and 25th inst. The following are the names of the prizetakers:—

Spanish.—First, J. Kerr, New Scone. Second, W. Paterson, Langholm. Third, A. Ridpath, Edinburgh. Highly Commended, W. Bruce, St. Leonard's Bank.

Dorkings.—First, G. Muirhead, Durdie. Second, J. Anderson, Meigle. Third, A. Macfarlane. Highly Commended, G. Brand, Bathgate.

Game.—First and Second, J. Anderson. Third, W. Donaldson, New Scone. Highly Commended, D. Gellatly, Meigle; J. J. Wilson, Darlington. Commended, J. M'Gregor, Crieff.

Cochins.—First, J. Meff, Aberdeen. Second, Mrs. Oswald, Dunnikier. Third, C. Pease, Darlington.

Brahmas.—First, K. Jopp, Aberdeen. Second and Third, Mrs. White, Castle Huntly. Highly Commended, J. Rutherford, Fife.

Hamburghs (Pencilled).—First, W. R. Parks, Melrose. Second, R. Macgregor. Third, G. Walker, Selkirk. Highly Commended, Mrs. Brown, Abercairny.

Hamburghs (Spangled).—First, H. Corrie, Ardrossan. Second, W. France, Crieff. Third, Mrs. Brown.

Bantams (Game).—First and Second, J. Anderson. Third, R. Macgregor. Highly Commended, F. L. Roy, Nenthorn. Commended, A. Robertson, Burntisland.

Bantams (Any variety).—First, F. L. Roy, jun. Second, J. R. Jessop, Hull. Third, Master W. H. Pople, British Hotel.

Ducks (Rouen).—First, J. Hardie, Sorbie Ewes. Second, J. Anderson. Third, Mrs. D. Cochrane, Lundie Mills.

Ducks (Any variety).—First, A. Huggart, Fife. Second, J. R. Jessop, Hull. Third, J. Hardie. Highly Commended, W. Paterson.

Any Other Variety.—First, Mrs. White. Second, J. Allan. Third, W. R. Parks, Melrose.

Selling Class.—First, D. Gellatly. Second, A. Ridpath. Third, J. Allan. Highly Commended, J. S. Smith, Inchbrakie; T. Baines, Bridge Haugh; A. Macgregor.

Sweepstakes for Single Cocks.—*Spanish.*—First, A. Ridpath. Second, W. Bruce, St. Leonard's Bank. *Dorking.*—First, J. Anderson. Second, J. Allan. *Game.*—First, J. Anderson. Second, J. Laing, Glendeughie. *Bantam.*—First, R. Macgregor. Second, F. L. Roy, jun.

VENTILATING INCUBATORS.

"E. S.'s" letter in your Number of the 8th of January shows, as he says, that he has devoted much attention and observation to the subject of incubation. Damp atmosphere, temperature as steady as possible at 103°, every attention to be paid to the effect of external temperature, and constant ventilation, are, as he writes, the main points, and they are those that I have kept steadily in view in the construction of my patent incubator, and which are contained in my "Directions."

I am glad to find that some one else besides myself is impressed with the necessity of constant ventilation—a point that I believe has been lost sight of, and is not provided for by any other incubator but mine.—Fred. H. Schroder, *Rickmansworth.*

SWARMS CLUSTERING OUTSIDE THEIR OWN HIVE.

VARIATION IN THE COLOUR OF HYBRIDS.

I have before remarked on bees swarming or clustering with their queen outside the hive when young queens were being brought forward, and that such swarming or clustering very often took place at night. A case of this kind happened with me this year, which I will relate, as the result corroborates the statement of Mr. Fox, of Kingsbridge, relative to two queens being in a hive at one time.

On the 22nd of July at 8 P.M. I noticed the bees of a hive lying out very much. It had been a warm day, but no honey was gathered. I was somewhat surprised at such numbers lying out, but on account of the heat I paid no heed to it further than getting them into their hive again. Next day I deprived another hive of its queen, and exchanged their combs, transferring them from one to the other for the purpose of raising queens. I suspected nothing until about three weeks afterwards, when I noticed a good many young black bees in the hive which had pure Ligurian combs, giving evidence of the existence of a young queen which had been hybridised, and showing plainly enough that two fertile queens had existed at one and the same time, as a subsequent examination proved by discovering the old queen still alive, the young one having evidently been thrown out. This case shows how careful we ought to be in raising queens from hives in respect to which any doubt may exist as to their having the original queen.

I am not sure but that a similar occurrence has taken place more than once this season, as in the case of several queens which were raised from a pure stock their progeny showed very little of their Italian origin. In a number of crosses which have occurred between the Italian and black bees there is much variation; in one case in which a black queen has been crossed there is not more than one marked bee in the hundred, while others show about one-half.

I may here mention that my views in regard to hybridisation are in accordance with those of Mr. G. B. Fox, and in opposition to those of Mr. F. H. West.—A Lanarkshire Bee-keeper.

[May not this apparently anomalous variation in the colour of the progeny of hybridised queens be accounted for by the fact that a queen bee does not always restrict herself to one drone?]

TO HIVE BEES IN A MOVEABLE COMB HIVE.

There is more difficulty attending this than with box hives, yet it is easily accomplished. Some think it best done by spreading a sheet as smoothly as possible in front of the entrance, upon which the bees are shaken close to the entrance, when generally with fanning wings they will accept their new home. If they do not go in rapidly enough, with a goosequill brush them gently in, or with a spoon direct their motions toward their new abode. Bees once shaken in the swarming season on a sheet are not apt to take wing again, since they are loaded with honey, for in that state they invariably leave the old colony.

There is another plan that we prefer—remove the honey-board*, and separate from the centre of the hive three or four of the frames, by sliding them to either side, and then in this opening shake the bees either from the bush or basket, slide the frames back to their places, replace the honey-board by sliding it on from one end of the hive, so as to avoid crushing the bees, and the operation is finished. The few that may return to the bush or adhere to the hiving basket, may be shaken in front of the hive entrance, and will quickly go in. When quiet, remove to permanent stand without delay.—(*American Bee Gazette.*)

* *Anglice*, Crown-board.

BREEDING IN SUPERS.

In the second column of page 80 in your last issue reference is made to "narrow slits one-fifth of an inch wide." I may here state that I have always been in favour of the collateral system, and for thirty years I have worked with much success Pettitt's collateral hives. The crown-boards of the stock hives are pierced with narrow slits three-sixteenths of an inch wide, or rather smaller than one-fifth. I have worked with these hives four glasses upon the top when the bees have been working in the collateral super, so that they have actually been working in five compartments or hives at one and the same time. The subterraneous communication between the stock hive and the collateral super has also been provided with a "grating" cut in wood, and I do not believe either of these supers was ever favoured with a visit either of the queen or drone bee. I have taken away the collateral super containing nearly 50 lbs. of the purest virgin honeycomb, without the slightest evidence of a visit from either the queen or a drone. I believe one great advantage in Pettitt's arrangement is that the communication from one hive to the other is in the floor-board, and the ventilating properties of this hive are such that the temperature of either box can be so regulated as not to interfere with that of the other. These narrow slits must be cut in the wood. Both wirework and metal castings I have tried, but without success.—Sunbury.

STARVATION IN THE MIDST OF PLENTY.

The late protracted frost broke up to-day (January 23), and the inhabitants of my twenty-two Ligurian stocks, with one exception, lost no time in availing themselves of the favourable opportunity for exercise in the open air, disposing of their dead, &c. An examination of the exceptionally quiescent stock proved that its unfortunate inhabitants had literally succumbed to famine in the midst of plenty; having exhausted what honey was stored in the central combs the severe cold prevented their obtaining access to those at the side, and in this way they were starved to death with both sealed and unsealed food within their domicile. This starvation in the midst of plenty is so frequent in America that bee-keepers are in the habit of guarding against it by boring a hole about an inch in diameter through all the combs from one side of the hive to the other, so as to permit the bees to obtain access to every comb without passing round their edges, but this is the first instance in which a catastrophe of the kind has come under the direct observation of—A Devonshire Bee-keeper

OUR LETTER BOX.

Husking Buckwheat.—*Inquirer* wishes to be informed how to separate the husk from buckwheat.

Salt for Fowls (*E. S.*).—Salt is said to be injurious to poultry. We never knew a fowl constipated, except in cases of inflamed bowels.

Mistake in Catalogue (*W. Bradley*).—As the bird was in its right place before the Judges went round to determine their awards, you could not have been injured; consequently you have no justification for suing the Committee.

Abscess in Fowl's Lungs (*A. F. Newman*).—No treatment could have saved your Brahma Pootra cock. The fungus-like substance which you enclosed was the discharge from an abscess in the lungs. The cause of the diseased lungs was possibly exposure to the severe weather. Your other Brahma Pootra which has "entirely lost the use of his legs," if that be literally true, had better be killed. Before doing so try what effect bread soaked in ale, and two grains of sulphate of iron daily, will have.

Dandelion Leaves for Fowls (*E. S.*).—The leaves of dandelion boiled and mixed up with barley meal may form an excellent food for fowls, but we never knew them used, nor do we know whether fowls would relish such bitter diet.

Washing Poultry (*W. G.*).—White Cochin China fowls may have their feathers washed with soap and water. After washing keep them until dry in a large hamper or an enclosure, the floor of which is quite covered with clean straw.

Rabbits (*Idem*).—"The Rabbit Book" will suit you. You can have it free by post from our office if you enclose seven postage stamps with your direction.

Ligurian Bee (*A North Staffordshire Bee-keeper*).—The bee is a distinctly marked Ligurian. We have no doubt that your explanation that the queen of your hive had met with drones from a Ligurian hive five miles distant is correct.

Ligurian Queens (*A Lanarkshire Bee-keeper*).—One guinea is the usual price for a warranted queen of this variety.

WEEKLY CALENDAR.

Day of Month	Day of Week	FEBRUARY 7—13, 1867.	Average Temperature near London. Day.	Night.	Mean.	Rain in last 39 years.	Sun Rises.	Sun Sets.	Moon Rises.	Moon Sets.	Moon's Age.	Clock before Sun.	Day of Year.
						Days.	m. h.	m. h.	m. h.	m. h.	Days.	m. s.

13	W	Magnolia conspicua.	44.0	29.5	36.7	14	21 7	8 5	52 11	18 2	9	14 29	44

From observations taken near London during the last forty years, the average day temperature of the week is 44.8°; and its night temperature 30.5°. The greatest heat was 65°, on the 10th, 1831; and the lowest cold 0°, on the 13th, 1855. The greatest fall of rain was 0.67 inch. N.B.—The Calendar contains the names of plants flowering in the greenhouse.

A GOSSIP ABOUT POTATOES.

I HAVE lately been reading through my papers on the Potato, previously published in these pages—how rapidly the years seem to have passed away!—and the reperusal has impressed on me the need of caution, and never to become too determined and certain upon any one point or principle of cultivation, or to fancy that one has drawn a line beyond which further progress is not possible, and, above all, not to take too much conceit to oneself about that last new offspring of thought, for very likely it may turn out to be only new because it has been forgotten.

I find by my writings that I have been careful in these respects; but I am a reader of old books upon a variety of subjects, and it is astonishing how often I find the very ideas and doings that I could conscientiously have laid claim to as the independent workings of my own brain. Fine lessons these old-world recurrences afford; they serve to take down conceit, by showing that there have been and always will be others as good and clever as oneself; and that the best plan for a man who wishes to make himself useful in his day is first to prove his theories by practice, and then to publish the results

This must be my excuse for not addressing you lately. Dame Nature for my practical hobbies insists upon time, and ready writers are so very quick that if one did not "fruit first and write afterwards," the task of defending oneself would not be altogether so very easy; besides, in the midst of tighting one cannot write, and about fourteen months ago a challenge was thrown down to me, when referring a querist to some printed correspondence of mine, "Oh, ah!" said my questioner, "it's all very well for you scribbling fellows to write this and that, ten to one it is all theory. Give me one practical man before you all. Why do you not show, and go in and win with the fine productions brought about by the practice you describe? then one could feel that it was not all bosh!" Pleasant to hear, certainly, and this writer felt himself "scratched;" so, in defence of the "scribbling fellows," and to encourage the others, I did "go in," and I did "win" in less than a year two medals, twenty-three first-class certificates, one extra prize, and two high commendations at the Royal Horticultural Society's Shows at South Kensington. Perhaps he will cry, "Braggadoccio!" And so it is; and why should I not be proud of being so commended? I am; and now to my "Gossip."

Cultivators' minds are now opening to the subject, and after perusing the papers of recent writers about the Potato, I wish to show how my practice and opinions respecting this esculent may agree or clash with theirs, and to let you know how its cultivation has fared with me during the last untoward season.

My frame and orchard-house were too much crammed with other occupants last season for me to attempt the production of early Potatoes there, and such is the case at present; so I adopted, and intend to adopt for the future, the excellent plan stated by your spirited and untiring correspondent "Forwards," at page 22, No. 198, Vol. VIII. On March 23rd I planted Webb's Telegraph, Coldstream Early, Shutford Seedling, and Mitchell's Early Albion, with an eye to exhibiting those kinds at the International Horticultural Exhibition in May, but to find that I had placed too much faith in the good qualities attributed to Webb's Telegraph. Coldstream Early took the lead of Shutford Seedling and Mitchell's Albion; it came into use the soonest by ten days, and by May 18th I had fine samples of the last three sorts. Webb's Telegraph, however, was fully three weeks behind the rest. I felt sadly disappointed, and it caused me not to exhibit new Potatoes, as I had determined to show a set of four early varieties. Coldstream Early is now placed first upon my books, it having beaten my previously crack sorts, Mitchell's Albion and Shutford Seedling. I saw, also, that Mr. R. Budd, gardener to the Earl of Darnley, was within very little of taking a first prize with it at the Great Show.

However, some varieties of Potatoes I have had in cultivation for years, others for a few seasons on trial only, but these I have, nevertheless, proved on different kinds of soil, and a few sorts are quite new to me, having been only one year on trial. I do not think we are justified in condemning a variety of Potato until we have proved it for two or three years on different descriptions of land. If it continues to prove a bad flavourless sort on soils varying from heavy to light, then we may fairly speak badly of it. It is a great satisfaction for me to find that to many of the sorts I have tried, and which I have recommended in these pages, excellent characters are given by those who have cultivated them in soils entirely different in texture from that of this garden, where I grow them very good. It consists of a stiff, stony loam, about 30 inches deep, resting upon a subsoil of clay that holds water like a basin, and it is much shaded by trees. I was formerly much puzzled to grow a Potato fit to be eaten, and, in fact, I never could induce a coarse-foliaged kind to yield me a crop at all. It was all tops and no bottoms till sixteen years ago, when I first began to feel my way on the ridge-and-trench plan with a coarse-topped kind called Cornish Kidney, and my man at that time—poor John Brotherton—reported in the neighbourhood that I was "going to grow Potatoes upon raised banks sufficient to form a Roman encampment!" but he was an old soldier, and, I fear, sometimes shot with a rather long bow.

Whilst writing this paper I have received a letter from a gentleman, a perfect stranger to me, but a great connoisseur of Potatoes, who lives near Bar Point, on the coast of Devon. The letter comes in so appropriately in respect to what I have stated above that I will quote an extract here. "The Yorkshire Hero I was getting forward, so the germs are set, yet I will pack it most carefully for you; the North

Riding Beauty (round, a late keeper), is not much sprouted; and of Thomas Almond's first early (the first year public, still almost unknown), I have put by for you some of the least sprouted I could find." I have had a great hankering after those kinds ever since Mr. Rudelyffe first informed us about them in Vol. X., page 165, No. 257. The extract concludes, "I have also a Potato which I value—Daintree's Seedling Kidney. I had it early last year direct from Fen Drayton. I think it is superior to the Lapstone, which is very good with us, but soil effects such wonders for good or evil; yet name it, and I will send you a sample." Now, the soil about Putsborough must be quite different from this at Woodstock, and I believe I received the very first tuber of his Kidney seedling that Mr. Daintree ever sent out. It was sent in a letter through the post-office, and was much damaged by the post-office stamping. I kept Mr. Daintree three years in suspense before I could quite decide upon its merits, but I am happy to say he lived to know that I grew it successively upon three different soils, and then I felt a pleasure in recommending it as being a Potato of the same strain as the Lapstone, and even superior to that very excellent variety. From what "D., *Deal*," said about it (No. 9 in his list, Vol. XI., page 463, No. 299), I expect it will also rank well with so good a judge, and in a soil different from that of my Devonshire correspondent.

Allow me here to state that I quite agree with Mr. McDonald, of Woodstock Park, Inistioge, in what he says about another *protégé* of mine, Coldstream Early, at page 464 of the same Number of The Journal of Horticulture. It is this sort of cross-examination upon different soils that we want before new kinds of Potatoes are sent out by the raisers. My object is to prove what are the best sorts which can be obtained for the rector's table, and the supply of our household. I have been four years proving my Onwards seedling to my satisfaction on different soils, and I am now sending it to experienced growers upon various soils, requesting them, in the event of the kind not proving entirely to their satisfaction, to be good enough to destroy every tuber, as I should feel sorry to offer a Potato to the public under my name, unless it were quite first-rate. Raisers of new sorts err in being in too great a hurry in sending out their seedlings. Including the present year I shall have been five years in making a trial of fifty sorts, dating from the seeds maturing in the berry, and although many of the issue turned out what for the first three years I thought very good varieties, yet I decided that they were not superior to sorts already in cultivation; so of such I took the precaution to boil into pulp in a copper whatever we did not consume, and with this pulp watered the Rose trees, and the result was, that we never had Roses in finer bloom.

I have now only three kinds left out of the fifty—namely, Russet Kidney, Beehive, and the Onwards, and I believe I shall have to consider the last only as worthy of perpetuation, perhaps not even that, if I do not succeed in obtaining good reports of it this year from a distance. My friend, Mr. Alexander Dean, of Maybush, near Southampton, is the only person at present besides myself who has made a trial of my seedling. He says, "Fenn's Onwards, a seedling of his own, a second early round, good both as to crop and quality." Mr. Dean exhibited sixty varieties of Potatoes at the Royal Horticultural Society's gardens, in September last. A notice of them appeared in the October number of the "Florist and Pomologist."

Although the labour of five years is only likely to produce me one Potato, I am now about sowing two more choice crosses, numbering about one hundred seeds, from which I hope to produce something superior, although I fear I shall not be able to arrive at the characteristic stated by my brother at a cricket-match dinner given last year. He complained of the badness of the kind served at table, and joking retorts from his cricketing friends arose as to "what he knew about Potatoes?" "Well," he said, "he certainly could tell whether a Potato was good or bad when eating it; but he had a brother living in Oxfordshire, who was a connoisseur of Potatoes, and could judge of them in their raw state; that he had just raised a new sort, as even and round as a cricket ball, and he was merely waiting before he let it out, to produce on each tuber an imitation of the seams."—Upwards and Onwards.

(To be continued.)

EDGING FOR WALKS.

In reply to your correspondent an "Ayrshire Gardener," I venture to give my experience with regard to a substitute for a Box-edging, having been in a similar dilemma. I have an oval bed in the middle of my garden, with an Apple tree in the centre, the bed filled with Lilies of the Valley. The Box-edging did not thrive owing to the drip from the tree, or being overgrown by the Lilies: consequently every two or three years it had to be replaced. After one of my visits to the Royal Horticultural Gardens I substituted an edging of Messrs. Rosher's cable-pattern terra-metallic tiles, of two sizes, the smaller to turn the oval more neatly. The tiles were laid in with only the cable pattern above the ground; the chinks, unavoidable in the turning, were filled in with Portland cement, and the whole painted a dull green, so as to resemble as nearly as possible the colour of the Box in the other parts of the garden. The result has been very satisfactory. I think this is the third winter, and I have not had to replace one tile. I was careful to have terra-metallic tiles.—F.R.H.S.

CHRYSANTHEMUMS NEW AND OLD.

Whatever may betide other florists' flowers, however the Pansy may be snubbed, the Dahlia sneered at, and the Auricula cold-shouldered, there is no fear of the Chrysanthemum being passed by. Even the bedder-out patronises it, for certainly one of the best beds that I saw at Battersea Park last season was composed of Mr. Bull's variegated sort Sensation; and as the Chrysanthemum, happily for its fame, comes into flower when the glories of the garden have faded away, and all looks dreary save where this plant has been allowed to linger; as, moreover, it is so easily propagated, and bears itself so bravely and so well amidst the smoke of our huge metropolis, it is likely to have a prolonged period of favour. Hence Mr. Salter, to whom we owe nearly all the fine varieties now in cultivation, need not be afraid of a time when his winter garden will be deserted, and the tide of visitors which finds its course there during the dreary month of November will be stopped in its course. Were it so, one of the chief pleasures of a visit to London in that month of fogs and dreariness would be lost. I see nothing in a Chrysanthemum show, but I do confess to a real enjoyment in a stroll through the well-arranged greenhouses in which Mr. Salter year by year places his favourite flowers. Such a stroll I had in November last, and the results of it I now chronicle; and inasmuch as the time for purchasing is now at hand, I may in some way be a guide to those who are seeking to add to their collections.

I must here, however, confess to a piece of heterodoxy—viz., that I think the incurved flowers have now reached pretty well their acme, and that in order to obtain brighter colours we must try the reflexed sorts, infusing, it may be, some of the blood of Mr. Fortune's last introductions from Japan. In one sense these incurved flowers are disappointing: the opening bud gives promise of bright colour, but by the time that the flower is fully opened the back of the florets is alone exposed to view, and, consequently, a good deal of the richness of the colouring is lost; but in the reflexed flower, which I think may with care be obtained as full as some of the varieties of reflexed Asters, the front of the florets is that which is exposed to view, and consequently a brighter-coloured flower is likely to be obtained. Mr. Salter mentioned to me that Mr. Fortune's Japanese varieties, which were at first neglected, are now being sought after; and this is probably a symptom of an alteration in taste which will effect the object I allude to.

As usual, Mr. Salter has a large number of varieties to be introduced to the public this spring. Some of these had not been named at the period of my visit, but of those which had I noticed Lady Talfourd, beautiful silvery rosy lilac, a fine incurved flower; Faust, a chestnut red; Countess of Warwick, fine creamy white; Madonna Mary, a large-petalled flower; Rosa Mutabilis, a delicate pencilled flower; Dr. Lindley, fine amber, a beautiful flower; Purpurea Elegans, quite new in colour, of a rosette form, and very good in all respects; Yolande, light blush white, silvery lilac back to petals; Gold of Ophir, not probably a show flower, but of good habit; Iris, a large incurved flower, bright orange, with purplish back.

Of the flowers of 1866 the following seem to me those most deserving of cultivation:—Amabilis, delicate blush, incurved; Compactum, an excellent conservatory flower, blooming early, and of admirable habit; Countess of Granville, fine white, a reflexed flower of great beauty; Crimson Velvet, beautiful velvety crimson, the darkest and brightest of all the high-coloured Chrysanthemums; Gloria Mundi, a splendid brilliant yellow, a seedling from Jardin des Plantes, and when I say

superior to that fine flower, I think it is enough to stamp its merit; Golden Beverley, a fine canary-coloured flower, a sport from that fine deep flower Beverley; Hereward, large, purple, with a silvery back to the florets, very compact; Isis, medium-sized, very double and compact; John Salter, reddish crimson, shaded with orange—I should be sorry to think that a flower so named as this was not first-rate, but I have misgivings as to its centre, with me it did not fill up so well as it ought, and I saw several blooms at Mr. Salter's in a similar condition; it is a fine flower if this defect is not general;—Josiah Wedgwood, rosy carmine, close and compact; Miss Eyre, blush late-flowering anemone, of medium size and dwarf habit; Mr. Gladstone, dark reddish chestnut, incurved; Sylvia, rosy lilac, with silvery back.

Of the Pompones of 1866 there were—Fairy Nymph, fine pure white, with round florets; Little Beauty, white, bordered with delicate rosy pink; Marie Stuart, lilac blush, with sulphur centre; Prince Victor, dark red maroon; Rose d'Amour, clear rose, very full and free; and Torfrida, bright golden amber.

Of older flowers in the large-flowered section I would recommend the following:—

*Aimée Ferrière, silvery white, beautifully tipped.
Alba Multiflora, white, incurved.
*Alfred Salter, delicate pink.
Annie Salter, golden yellow.
Attraction, blush, margined with pink.
*Bella Donna, delicate lilac, with light centre.
Bernard Palissy, fiery orange.
*Beverley, fine white.
Blanche of Castile, fine incurved, white.
Cardinal Wiseman, early-blooming, reddish crimson.
*Cleopatra, rosy blush.
Dr. Brock, reddish orange.
*Duchess of Wellington, delicate rose, tipped with blush.
Dupont de l'Eure, an old flower, a bad grower, but very fine.
Edith Dombrain, lilac blush, a beautiful conservatory plant.
*Eve, primrose sulphur.
General Bainbrigge, dark orange, amber and gold centre.
Golden Eagle, indian red and orange.
*Golden Queen of England, golden canary colour.
Golden Trilby, a sport from Trilby, clear yellow flowers.
Hercules, large red carmine.
*Her Majesty, silvery blush, compact habit.
Hermine, blush, tipped with purple.
Jane, silvery pink, a good close flower.
*Jardin des Plantes, splendid golden orange.
King of Denmark, rosy lilac.
*Julie Lagravère, a fine old dark variety.
Lady Carey, rosy lilac, silvery back.
Little Harry, bright golden amber.
Lord Palmerston, rosy amaranth, tipped with blush.
*Luther, large rosy crimson.
Marçeau, rose, bordered white.
Mr. Brunlees, large; indian red, golden tips.
*Mrs. E. Miles, bright yellow.
Mrs. Kelnes, blush.
Orange Perfection, dark salmon orange.
*Prince Alfred, splendid rosy crimson.
*Prince of Wales, dark purple violet.
*Princess of Wales, pearl white, delicately tinted rosy lilac.
Rev. J. Dix, orange red.
*Sam Slick, ruby, with bronze tips, something like Stafford's Gem Dahlia.
Sir Stafford Carey, dark brown chestnut.
*Sparkler, red, tipped with bright orange.
Triomphe du Nord, large, light red chestnut.
*Venus, large, lilac peach.
*Virgin Queen, pure snow white.

POMPONES.

*Andromeda, cream, with brown points.
Auréole, crimson and orange.
Aurore Boréale, yellow buff.
*Bijou de l'Horticulture, charming sulphur white.
Capella, dark red chestnut.
Citronella, pure clear yellow.
*Comte Achille Vigier, pale salmon mottled.
*Duruflet, rosy carmine, very fine.
Fairest of the Fair, lilac blush.
François 1re., reddish orange.
Golden Aurore, bright gold yellow.
*Julia Engelback, yellow and brown points.
La Vegue, bright gold.
*Lizzie Holmes, canary yellow, tinted with rose.
Lucinda, rosy lilac and blush.
*Madame Fould, cream, splendid shape.
*Marabout, white, fringed.
Mdlle. Marthe, very fine, dwarf, white
Minnie Warren, rosy blush, with yellowish centre
*Mrs. Dix, blush, bordered rose.
President Decaisne, rosy carmine.
Rose Trevenna, rosy blush.
*salamon, dark rosy carmine.
*Little Gem, delicate peach blush, late-blooming.
*Trophée, rose mottled, fine.
White Trevenna, a beautiful sport of Rose Trevenna.

ANEMONE-FLOWERED, LARGE AND SMALL.

*Fleur de Marie, fine white.
King of Anemones, large, crimson purple.
Lady Margaret, large, pure white.
*Marguerite de York, canary and dark yellow.
Prince of Anemones, large, lilac blush, and fine high centre.
*Queen Margaret, rosy lilac.
St. Margaret, bright orange.
Boule de Neige, white.
*Cedo Nulli, and its sports Golden and Silver Cedo Nulli.
Madame Montels, white, with yellow centre
*Madame Sentir, pure white.
Mr. Astie, bright golden yellow.
Reine des Anemones, white, very fine.

For those who might wish for a smaller number I have marked with an asterisk a more select collection of varieties, which are, I think, sure to give satisfaction, whether grown in pots or out of doors.

The past season was a peculiar one, many persons having sorely complained of their pot plants, while those in the open air blossomed more finely than I ever recollect, no frost having occurred to hurt the bloom until they had nearly if not quite completed their flowering.—D., *Deal*.

RUBBISH HEAPS.

Such is the title of a useful article by Mr. R. Fish at page 273 of the last Volume of your Journal. Mr. Fish states that he has two or three heaps, which he treats differently. He describes, indeed, four heaps, but he only treats the four in two different ways; the first two, consisting of weeds seeding (!), short grass from the lawns, &c., to pass through, if I correctly understand him, the process of fermentation, and the other two, consisting of tougher refuse matter, to be charred.

In regard to these heaps Mr. Fish justly states, "that much future labour would be avoided, as respects weeds, &c., were they always kept distinct by the workmen;" but "there's the rub." I should like to know the secret of his success, if he does succeed. My own efforts to produce good and clean leaf mould have been repeatedly baffled, from the difficulty of "insensing" (excuse the provincialism), the labourers with the necessary care to be observed in separating the vile from the refuse. Even the one whom I regard as head gardener or overseer I have found it hard to make an impression upon in this respect; he has sometimes smiled when I have been delivering my injunctions, evidently setting me down as "mighty too particklar." The consequence has been, that the beds and borders, which have been dressed with the mould from these heaps, have sometimes been covered again with the same stones which the year before had been carefully picked or raked off, or swept from the gravel walks; and, as the spring has advanced, plentiful crops of weeds, or of flowering plants, as bad as weeds when growing where not wanted, have started up in all directions. The negligence and indifference usually betrayed by this class of workmen arise chiefly from the want of careful training in their early years: therefore I prefer to put intelligent boys to work at weeding and separating the refuse, for I find them more docile and less prejudiced.

In spite, however, of the utmost care, dry and windy weather often makes sad work whilst the heaps are accumulating. The lighter litter at the top, especially if it be fallen leaves, is blown about and intermingled with the adjoining heap; whilst groundsel, sowthistle, and other seeding weeds (these I adjudge to the heap for burning), will, though thrown on green, rapidly mature their seeds, which are scattered by the wind in all directions. I was, consequently, induced at length to construct two pits about 14 feet long, 5 wide, and 8 deep, inside measure. They are built of untooled stone, plenty of which is to be had in this neighbourhood, the smoother side to the pit, and are coped at top with waste timber lying about on the premises. The two only cost £5. They nearly join each other, end to end, and are not in the immediate vicinity of the rubbish heaps.

When one of these pits is about one-third filled with clean refuse, I have 1 cwt. of salt spread over it, and a little waste soil on that, to the depth of about 3 inches: old turves, balls from old potted plants, road-scrapings, or any other. The heap soon sinks to one-half of its previous height, during which time fresh stuff is continually being thrown in, which, when it is about 5 feet in depth, is treated as before, until a tolerably solid mass reaches the top. This will again sink a little, when it is treated with a dressing of fresh quicklime, slacked with a strong solution of salt and water, and spread about 1 inch in thickness. Then more clean refuse is piled on, and a good coating of soil packed about it, and it is left to stand while the second pit is filled and treated in a like manner.

By the foregoing process fermentation is continually going on in the different substances whilst the pit is filling; the grass from the lawn mowings (and the smallest quantity is in this way useful), the salt, and the rain, all tending to promote decomposition, and if a few seeds are now and then thrown in by mistake or heedlessness, their vitality is soon destroyed by the fermentation going forward.

I may also state, that the men's water-closet, which is out of doors, is once in the year emptied into the pit, when it is about one-half or two-thirds filled, and greatly adds to the quality of the mass. This becomes immediately deodorised by the soil or refuse thrown upon it, and it fertilises the plants in the garden, when rained upon or watered, quite as effectively as liquid manure, and without the same offence to the olfactory

nerves, which ought never to be annoyed in a garden, and without danger to the leaves of the plants.

I have only to add that the first pit was nearly twelve months in being filled, having been commenced at the fall of the leaves, or October, in one year, and not completed till October in the following year, when the second pit began to be filled. The first pit, however, is left closed up, like a Potato-pit, for twelve months longer, while the second pit is filling, and is not emptied for use till the October of the third year—*i.e.*, two years from the time when the filling process commences, when it lasts for all the purposes required in that autumn and the following spring, and is excellent mould, or "prime stuff" as the men call it. The process of refilling the first pit is commenced as soon as the second pit is filled, when the latter is in turn hermetically sealed, and so remains for twelve months longer. By this means one pitful becomes thoroughly decomposed and ready for use, while the other is preparing. The stable manure is reserved for hotbeds and kitchen garden purposes.

I shall be greatly obliged by any further hints or information on this subject from any of your readers, for I am always but a learner.—Philokepos.

ANNUALS FOR ORNAMENT AND BOUQUETS.

A correspondent, "H. F. F.," says, "I have just been compelled to turn my flower garden into a playground, and have, consequently, lost a great number of perennials, bulbs, &c., and in my new flower garden, both for beauty and bouquets, I must trust in a great measure to annuals." Now this is exactly what many may say of their gardens besides "H. F. F." The massing or bedding-out system has made such rapid and deep inroads into our mixed borders as to completely stamp out of existence the less troublesome, least expensive, and certainly most useful of all flowering plants—viz., hardy flowering shrubby, herbaceous, and bulbous plants, which, though not affording any striking effect, were ever the resort when a bouquet was wanted. Many of those who advocated such plants being discarded, and consigned to the rubbish heap, have often had to wish they had that mixed border to run to.

Where cut flowers are in request I think no greater mistake can possibly be made than destroying borders of perennials and flowering shrubs so that the space may be devoted to summer plants in masses, for the latter cannot be cut much from without impairing their beauty and effect. It is folly to compare the two methods—namely, mixed borders of perennials, bulbs, annuals, and half-hardy plants, with the massing together of plants of one kind and colour; the systems are very distinct, and neither can be employed effectively if not in keeping with the surroundings. There are few, if any, gardens that could not well afford a border for herbaceous plants with flowering shrubs at back, and there are many the pleasure from which would be enhanced were they replanted with a selection of the best herbaceous plants. I consider a good border of perennials, bulbs, and flowering shrubs that bloom in spring, early summer, and autumn, when combined with Phloxes, Pentstemons, Antirrhinums, Dahlias, Ageratums, Salvias, Pinks, Carnations, Roses, and such bedding plants as Calceolarias, Verbenas, Pelargoniums, &c., with Asters, Stocks, Marigolds, Phlox Drummondi, and other annuals, may be made very effective, to say nothing of its adaptability for certain positions, and the variety it furnishes in contrast to the massing system.

Annuals at their best are but indifferent substitutes for perennials and bulbs, though they tell well as adjuncts; as substitutes they bloom when many herbaceous plants are over, but as adjuncts are indispensable, as they furnish bloom when that of the others is less plentiful. Some annuals are of no value for bouquets, though very desirable for decoration: such I shall distinguish with a * prefixed, and to make this paper as useful as possible I propose to give selections of the most useful and showy, so as to meet the various wants of the readers of this Journal.

Asters.—*For Exhibition*:—Reid's Improved Quilled, Truffaut's Perfection Pæony-flowered, and Victoria. *For Beds and Front Lines in Borders*:—(The above do well at the back, as they grow taller).—Pompone Imbricated, Dwarf Pyramidal Bouquet, Dwarf Chrysanthemum-flowered, and Miniature Bouquet. *Three Best Kinds*:—Reid's Improved Quilled, Truffaut's Perfection Pæony-flowered, and Dwarf Chrysanthemum-flowered.

Stocks.—Large-flowering German Ten-week, and Pyramidal Large-flowering Ten-week.

Phlox Drummondi in variety, along with Stocks and Asters, is invaluable for cut flowers, and no plants afford so fine a display as these when in full bloom. They furnish nearly every shade of colour.

TWELVE HALF-HARDY ANNUALS.

Marigold, French, various, 1½ foot.
Tagetes signata pumila, orange, 1 foot.
*Venidium calendulaceum, orange yellow, 1 foot.
Zinnia elegans, double, various, 2 feet.
Calceolaria scabiosæfolia, yellow, 2 feet.
Alonsoa Warscewiczii compacta, scarlet, 1 foot.
*Petunia hybrida (perennial) vars., 1½ foot.
Schizanthus Grahami, red and orange, 2 feet.
*Lobelia erinus speciosa (a perennial), blue, ½ foot.
*Heliophila araboides, blue, ¾ foot.
*Abronia umbellata, rosy lilac, trailer.
Ageratum mexicanum cæruleum, blue, 1½ foot.

TWENTY-FOUR HALF-HARDY ANNUALS.

The preceding twelve.
Salvia Rœmeriana, scarlet, 1 foot.
*Lobelia gracilis rosea, rose, ½ foot.
*Brachycome iberidifolia, blue, 1 ft.
Datura chlorantha, double, yellow, 3 feet.
Marigold, African, yellow and orange, 2 feet.
Salpiglossis, mixed, 2 feet.
Salpiglossis, Dwarf, 1 foot.
Martynia fragrans, purple, 2 feet.
*Oxalis rosea, rose, 1 foot.
*Nemesia compacta, blue, ½ foot.
Schizanthus retusus, scarlet and orange, 2 feet.
Portulaca grandiflora, double, various, ¾ foot.

HALF-HARDY EVERLASTINGS.

Acroclinium roseum, rose, 1 foot.
roseum album, white, 1 foot.
Helipterum corymbiflorum, white, ¾ foot
Sandfordi, yellow, ¾ foot.
Rhodanthe maculata, pink, yellow, and crimson, 1½ foot.
Rhodanthe maculata alba, white, 1½ foot.
maculata atrosanguinea, crimson, 1½ foot.
Manglesii, rose and white, 1 ft.
Waitzia corymbosa, white and amaranth, 1 foot.
acuminata, yellow, 1½ foot.

HALF-HARDY PLANTS WITH ORNAMENTAL FOLIAGE.

(*Annuals, or Perennials proving effective in the first season.*)

Perilla nankinensis, purple foliage, 1½ to 2 feet.
Amaranthus melancholicus ruber, blood-red foliage, 1½ to 2 ft.
Oxalis tropæoloides (O. corniculata rubra), dark bronzy foliage, ½ foot.
Salvia argentea, silvery foliage, 2 feet
Marvel of Peru, Gold-striped, 2 ft.
Cineraria maritima, silvery foliage, 1½ foot.
Solanum texanum, scarlet fruit, 2 feet.
Canna indica aurea vittata, golden flowers, 4 feet.
superba, scarlet, 3 feet.
Canna Warscewiczii, striped, 4 ft.
Sellowii, scarlet, 4 feet.
bicolor, red and yellow, 2 feet.
Fintelmanni, yellow, 3 feet.
nepalensis, yellow, 3 feet.
gigantea, red and yellow, 7 feet.
Ricinus borbonensis, large foliage, 6 feet.
lividus, green fruit, red stems, 6 feet.
macrocarpus, whitish foliage, 6 feet.
roseus superbus, rose-coloured fruit, 6 feet.
sanguineus, red foliage, 5 feet.
viridis spinosus, green spiny fruit, 3 feet.
Zea japonica, striped leaves, 6 ft.

HARDY ANNUALS.—SELECTION OF TWELVE.

Candytuft, dark crimson, 1 foot.
White Rocket, 1 foot.
Alyssum maritimum, white, ½ ft.
Leptosiphon densiflorus, purple, 1 foot.
Tropæolum Tom Thumb, Crystal Palace Gem, sulphur, dark spots, 1 foot.
Prince's Feather, crimson, 2 feet.
*Clarkia integripetala, double, rose, 1½ foot
integripetala marginata, rose and white, 1½ foot.
*Nemophila insignis, blue, ½ foot.
Linum grandiflorum coccineum (rubrum), scarlet, crimson centre, 1 foot.
*Saponaria calabrica, rose, ¾ foot.
Mignonette, Large-flowering, 1¼ ft.

SELECTION OF TWENTY-FOUR.

The above.
Virginian Stock, red, ½ foot.
Silene pendula.
Helichrysum monstrosum, various, 1 foot.
Calliopsis coronata, yellow spotted 2 feet.
Centaurea cyanus minor, various, 1 foot.
Erysimum Perofskianum, orange, 1½ foot.
Scabious, dwarf, scarlet, 1 foot.
Senecio elegans, double vars., ¾ ft.
Larkspur, branching vars., 2 feet.
Centranthus macrosiphon, red, 1 ft.
Poppy, dwarf French, vars., 1 foot.
Lupinus nanus, blue and white, 1 foot.

SELECTION OF FIFTY.

The preceding twenty-four.
Chrysanthemum coronarium, dbl., white, 2½ feet
yellow, 2½ feet
carinatum, yellow, white, and black, 1½ foot.
Calliopsis marmorata nana, marbled, 1 foot
Cacalia coccinea, scarlet, 1½ foot.
*Clarkia pulchella, double, rose, 1½ foot.
* pulchella nana alba, white, 1 ft.
* elegans rosea, double, rose, 1½ foot.
Kaulfussia amelloides, blue, ¾ ft.
Eschscholtzia californica, yellow, 1 foot.
Calendula Pongei, double white, 1½ foot.
Collinsia bicolor, purple and white.
*Convolvulus minor splendens, dark violet, 1 foot.
Lupinus subcarnosus, blue, 1½ ft.
*Œnothera bistorta Veitchi, yellow, crimson spot, 1 foot.
*Nolana atriplicifolia, blue, white, and yellow, 1 foot.
Tropæolum Tom Thumb, Beauty, orange spotted, 1 foot.
Tom Thumb Scarlet, 1 foot.
Whitlavia grandiflora, violet, 1 ft.
*Viscaria splendens, scarlet, 1 foot,
Delphinium cardiopetalon, blue, 1 foot
*Gilia rosea splendens, rose, 1 foot.
Invincible Scarlet Sweet Pea.
*Venus's Looking Glass, blue, ½ ft.
*Sanvitalia procumbens, double, yellow, ½ foot.
*Godetia roseo-alba, Tom Thumb, rose and white, 1 foot.

SELECTION OF ONE HUNDRED.

The preceding fifty
*Gypsophila elegans, white and pink, 2 feet.
*Eutoca Wrangeliana, blue, 1 foot.
Sweet Sultan, purple, 2 feet.
yellow, 2 feet.
*Linaria bipartita splendens, purple, 1 foot.
*Godetia Lindleyana fl. pl., rosy purple, 1½ foot.
Collinsia multicolor, crimson, lilac, and white, 1 foot.
Larkspur, Rocket, various, 1 foot.
Hyacinth-flowered vars., 1 foot.
Collomia coccinea, scarlet and yellow, 1 foot.
*Calandrinia umbellata, crimson purple, ½ foot.
Campanula Lorei, blue, 1 foot.
Catchfly, Lobel's, red, 1 foot.
Lobel's, white, 1 foot.
Eucharidium grandiflorum, red, 1½ foot.
*Eschscholtzia crocea, orange, 1 ft.
tenuifolia, primrose, 1 foot.
*Hibiscus calisureus, rose, 1½ foot.
*Nemophila maculata, white and purple, ½ foot.
Nigella hispanica atropurpurea, purple, 1½ foot.
Leptosiphon androsaceus, lilac.
androsaceus albus.
*Limnanthes Douglasi, white and yellow, 1 foot.
Sphenogyne speciosa, yellow, 1 ft.
*Silene pendula alba, white, 1 foot.
Lavatera trimestris, red, 3 feet.
*Gilia tricolor rosea splendens, rose, 1 foot
nivalis, white, ¾ foot.
*Sunflower, dwarf, yellow, 3 feet.
Sweet Pea, vars., 5 to 6 feet.
*Malope trifida, purple, 3 feet.
Love-lies-bleeding, red, 2 feet.
Lupin, yellow, 1½ foot.
Lupinus hybridus Dunnetti, rose, brown, and yellow.
*Convolvulus minor atropurpureus, violet purple, 1 foot.
*Anagallis grandiflora cærulea, blue.
Centranthus macrosiphon carneus, flesh, 1½ foot.
macrosiphon albus, white, 1½ ft.
Bartonia aurea, orange, 1½ foot.
Calliopsis cardaminifolia, yellow, 2 feet.
bicolor nigra speciosa, marbled crimson, 2 feet.
Centaurea americana, blue, 2 feet.
*Fenzlia dianthiflora, rosy lilac, ½ foot.
Lasthania californica, yellow, 1 ft.
Tropæolum Tom Thumb, yellow, 1 foot.
Tom Thumb, crimson, 1 foot.
King of Tom Thumbs, crimson scarlet.
*Saponaria calabrica alba, white, 1 foot.
*Poppy, Carnation, various, 2 feet.
Pæony-flowered, vars., 2 feet.

HARDY ANNUAL EVERLASTINGS.

Helichrysum macranthum, white, 2 feet.
macranthum nanum, red, 1 ft.
macranthum rubrum, red, 2 ft.
compositum maximum, var., 2 feet.
monstrosum, various, 1½ foot.
Helichrysum bracteatum, yellow, 2 feet.
bracteatum album, white, 2 feet
brachyrhynchium, yellow, 1½ ft.
Xeranthemum annuum, purple, 2 feet.
album, white, 2 feet.

HARDY ANNUALS WITH ORNAMENTAL FOLIAGE.

Atriplex hortensis rubra, red foliage, (2 feet if pinched) 3 to 4 feet.
Chenopodium atriplicis, purple foliage, 3 feet.
Helianthus argyrophyllus striatifolius, double, glossy foliage and bright yellow flowers, 4 feet.
macrophyllus giganteus, 10 ft.

I have grown the above annuals and consider them the best; but tastes may differ, and of those which I have named some may not succeed in particular soils and situations, or not so well as to be useful, and I may have omitted others that are desirable. For the names of such, I, for one, should be obliged. I will conclude with naming a few hardy annual climbers, twiners, and Grasses.

ANNUAL CLIMBERS.

Tropæolum majus, mixed, various, 6 feet.
majus, crimson, 6 feet.
majus, orange, 6 feet.
majus Scheuerianum, straw-coloured, spotted, 6 feet.
majus Scheuerianum carneum, straw, marbled scarlet, 6 ft.
peregrinum (canariense), yellow, 10 feet.
Convolvulus major (Ipomæa purpurea), albus, white, 6 to 10 ft.
major atropurpureus, dark purple, 10 feet.
major atroviolaceus, dark violet, 10 feet.
major Burridgi, rosy crimson, 10 feet.
quinatus, white, lilac spots, 10 ft.
aureus superbus, yellow.

Except in warm soils and situations, the varieties of Convolvulus major require the treatment of half-hardy annuals.

GRASSES.

Pennisetum longistylum.
Eleusine caput-Medusæ.
Bromus Schraderi.
Briza maxima.
Agrostis nebulosa.
Tricholæna rosea.
Lagurus ovatus.
Hordeum jubatum.
Brizopyrum siculum.
Avena sterilis.
Setaria macrochæta.
Paspalum elegans.

—G. ABBEY.

EARLY PEAS.

We have read with unmingled surprise the reported result of a trial of early Peas by "Ronnoc," at page 67 of this Journal, prejudicial to the new-established good character of our First Crop Pea. We can only conclude your correspondent has failed in procuring the genuine stock as introduced by us, and which was distributed last season in sealed packets only.

After the numerous testimonials which we have received as to the unqualified superiority of our First Crop Pea, besides the many favourable reports at various times in the horticultural journals of its good quality, further comments from us may be deemed unnecessary; but the following evidence of its character is worthy of notice, being the result of a trial by Mr. J. Veitch, of the Royal Exotic Nursery, Chelsea, an authority of undoubted experience:—

"I will here mention that all the novelties were procured direct from the firms sending them out.

"I made my first sowing January 16th, with the following kinds:—

	Bloomed.	Gathered.
"1. Carpenter's Express	May 6th	June 6th.
2. First and Best	„ 6th	„ 1st.
3. Carter's First Crop	„ 3rd	May 31st.
4. Ringleader	„ 3rd	„ 31st.
5. Essex Rival	„ 19th	June 9th.
6. Sangster's No. 1	„ 20th	„ 8th.
7. Dillistone's Early	„ 11th	„ 9th.
8. Tom Thumb	„ 12th	„ 7th.
9. Long-podded Tom Thumb	„ 20th	„ 7th."

This proves our Pea to be the earliest (excepting Ringleader, with which it is identical), and several days earlier than Sangster's No. 1.

This independent evidence we think will convince "Ronnoc," that the early qualities of our First Crop Pea are not overestimated, and that probably he did not procure the Pea from a reliable source.—James Cartea & Co.

ROYAL HORTICULTURAL SOCIETY.

The anniversary meeting of the Royal Horticultural Society is to be held on Tuesday next, when the Fellows will have an opportunity of exercising their privilege of electing their representatives to serve on the Council for the current year. The gentlemen who have been recommended by the Council, and whose names we announced in our last Number, are all in their several positions highly qualified to hold such a trust as it is proposed to give them. In General Grey we could not have a better representative of that class without which popular institutions in this country cannot well be carried on successfully; while, at the same time, will be secured that connecting link between the Society and its exalted Patron, which cannot fail to be highly advantageous to its interests. In the very names of the other two gentlemen who have been recommended —Major Trevor Clarke and Mr. Wentworth Buller—we have an assurance of a devotedness to horticulture and to the best interests of the Society, which requires no other confirmation than is exemplified in their past career. So far, then, we believe the Fellows may congratulate themselves.

For a great many years past, but more particularly for the last five years, the financial position of the Society has been a subject that has excited a solicitous and not unfrequently a deep interest in the breasts of the Fellows; and those who take a marked interest in the welfare of the Society look forward to the anniversary meeting with a very special interest as that at which the report of the Council is made, setting forth the condition and prospects of the Society. It is notorious that for several years the statements produced of the financial condition of the Society were comprehensible in the inverse ratio of the Society's prosperity, and for any one to arrive at a clear understanding of the subject from the accounts furnished in the report was next to impossible. Some of the statements show an inkling of how matters stood. In the year ending 1864, for example, even with the most favourable representations of the state of the revenue accounts, a balance was shown against the Society of £2784 16*s.* 3*d.* In preceding years the position of affairs was not more encouraging, and it may be useful to recall a few of the items of expenditure of those days, by way of encouragement or of warning for the present. On reference to former balance sheets we find the sums spent on the following items stated thus:—

	1862.	1863.	1864.	1865.
	£ *s.* *d.*	£ *s.* *d.*	£ *s.* *d.*	£ *s.* *d.*
Expenses of management	5990 1 2	4083 12 4	2830 6 4	2259 4 9
Kensington Gardens	7260 19 5	4033 4 7	3703 0 3	3323 14 1
Ditto labour only	1823 3 2	*879 5 10	1145 3 7	1155 4 11
Ditto salaries only	1341 16 10	1011 8 3	849 5 9	656 11 6

We shall have an opportunity to speak of Chiswick on another occasion. It will be seen from these facts that the affairs of the Society have been gradually improving, and the expen-

* We cannot pretend to explain how the labour this year should have amounted to a sum so much below that of the preceding and subsequent years; but it appears to show that it is possible to keep the garden in state of perfect efficiency for that amount.

diture, though it has been in excess of the income, has been diminishing, while, as we find from the published accounts, the permanent income has been on the increase. We look forward, then, with no ordinary amount of interest to the statement that will be laid before the meeting on Tuesday, as we anticipate to find an even greater reduction in expenditure as the result of the persistent and judicious economy inaugurated by the present Secretary, whose whole endeavour, we know, is to bring the Society into a state of solvency and usefulness. We do not anticipate that this end is to be attained speedily, nor do we expect to find that the forthcoming statement will show a balance on the right side, but if the balance which it does show, be it on the right side or on the wrong, be counted by as many hundreds as it was formerly counted by thousands, the Society will have good reason to be thankful, and to look forward with hope to the next annual meeting when, by a continuance of the same rigid economy on the one hand, and a liberal encouragement of the purely horticultural objects of the Society on the other, the Society will be in a position financially such as it has, perhaps, never before experienced.

ASPHALTING VERSUS GRAVELLING.

My property, The Grange, West Moulsey, has an avenue of a quarter of a mile from the gate to the house. The gravelled road is much worn-out, and I intend to have something done to it this year. I wish to know whether you would recommend gravelling or asphalting, and which of the two in the long run is the more durable?

On an average I should say a carriage would go over such a drive about four times a-day. The road is about 20 feet broad. —W. B. A.

[In such a long carriage-road we should decidedly prefer gravelling to asphalting. There is a good deal of trouble in mending asphalt when it breaks into holes, and very little trouble with gravel. Besides, if asphalt is not done in a peculiar way to leave a rough surface, and that would wear off, it becomes too smooth to give a foothold to the horses, and would be dangerous in frost. We like asphalting best round houses, stables, &c.; but our experience would lead us to say, Do not use it largely for roads if gravel is to be had.]

"THE MINIATURE FRUIT GARDEN."—Fruit-tree culture does not appear to be on the decrease if we may judge by the rapidity with which Mr. Rivers's little books issue from the press. We have now before us the fifteenth edition of "The Miniature Fruit Garden," which contains all that is to be found in the former editions and much more besides. One useful addition we observe in it is a "Miniature Fruit Garden Calendar," which gives instruction in what is to be done in the various months, and which will be of great service to the amateur.

CUCUMBER FAILURES.

HAVING noticed at page 86 inquiries respecting the cause of failures in growing Cucumbers I am induced to send my mite, knowing that anything tending to their more successful cultivation will be useful to many readers of this Journal.

Some years ago, in, I believe, two former gardeners' time, Cucumbers failed here; they are grown mostly in pigeon-holed pits with dung linings. Several lots of plants failed; the soil was blamed, fresh soil was procured: but in each case the result was the same, till at last it was doubted if they could be grown at all.

On my entering the situation nine years ago I heard of this; but, nothing daunted, I thought I would see what was to be done. I took soil indiscriminately, feeling sure that that was not so much to blame; but—and this is what I would wish unsuccessful cultivators to bear in mind—the water, not properly aired, had injured the plants fatally. I have seen, where such has been used, good fruit become quite disfigured by disease. The stems would gum and die away, till at last a fresh lot of plants was required. I never allow one plant to be watered, even in summer, with water not in good condition. If such is not ready when wanted I let the plants go another day, and if that prove a very hot one I shade a little to keep the plants from flagging.

Water can generally be properly prepared in the summer months by placing it in cans or other vessels exposed to the sun's rays; but even then, if the afternoon of the day be cloudy it is better not to use it.

Another point I always insist on is, when the plants are watered and shut up, and the sun is bright, that a little air early in the morning be admitted; in the summer, say at 7 A.M.

With such treatment I have met with success. During the nine years I have been here I have cut fruit from one lot of plants every year from March till December, and the quantity very abundant.

With respect to ridge culture, I have known plants go off much as "SUBSCRIBER" mentions, but I have found them do very well with me in the following manner:—

Choose a piece of ground as much facing the sun as possible. Dig holes 5 or 6 feet apart, and large enough to contain a barrowful or so of nearly short dung; replace the soil in the shape of a cone, place a hand-light on the top of each cone, and let it remain a day or two for the sun to warm the soil; then plant out, using water when required as before mentioned. I never take the hand-lights quite off, but harden the plants gradually by placing bricks under each corner, and leave them so all the summer, letting the plants run under their sides; by so doing the hand-lights protect the crowns from over-much rain.

I have found it a good plan, if the plants are at all exposed, to grow a row of Peas or Beans on that side as a protection.—GEORGE COULDREY, *Hardenhuish Park, Chippenham.*

THE INTENSE COLD AND ITS CONSEQUENCES.

FORT AUGUSTUS, INVERNESS.—The thermometer at this place registered on

January 3rd	7°	January 16th	12°
,, 5th	8°	,, 17th	13°
,, 7th	8°	,, 18th	10°
,, 15th	5°	,, 22nd	11°

These temperatures (all of which are above zero), are the lowest that have occurred here during the month. The instrument is placed against a wall facing the north-east, at about 5 feet from the ground. We have had a considerable amount of snow, but nothing in comparison with places farther to the east. In the neighbourhood of Inverness and Strathnairn it has, I believe, in some instances been upwards of 2 feet in depth.

I have just made an examination of my Roses, and find that with one exception, Monte Christo, they are all right. This variety, which I fear is quite dead, occupied the snuggest part of my garden, being against a south wall and protected from the east by a porch. On the same wall I have fine plants of Celine Forestier, Triomphe de Rennes, and Safrano. The last of these had some fern placed round it, but the other two had no protection whatever. It is to be regretted that Monte Christo is so tender, for this part of the country at least, as none of the darker varieties, with the exception, perhaps, of Empéreur de Maroc, opens so freely, and its perfume is unsurpassed.

I had a few Tea Roses in pots; I say had, for I fear they are all destroyed. They were placed under a south wall and carefully covered with fern before the frost set in, but notwithstanding the precautions used they are very much cut up. Madame Willermoz is quite dead, and the others, Madame Falcot, Madame Damaizin, Duc de Magenta, Devoniensis, Souvenir d'un Ami, and Madame de St. Joseph have been so severely injured that I entertain very little hope of their recovery. It was simply for the sake of experiment that I grew them at all, and I take this opportunity of stating, that I consider it a mere waste of time to attempt their cultivation out of doors in the north of Scotland. You may grow them well enough, and even manage to carry them through a pretty severe winter, but very few, if any, will ever open well, Gloire de Dijon always excepted. I had certainly two or three fair blooms of Madame Willermoz, but none of the others would open at all.

I must confess, however, that in this respect, with few exceptions, I was equally disappointed with the Hybrid Perpetuals but certainly there could not have been a more unfavourable season for Roses than the last. In June and July we had a prevalence of cold east winds, and their withering effect on the blooms was very perceptible, the petals in many instances were completely shrivelled up, and in others were much changed in colour. As instances, Paul Ricaut was only about a shade

deeper than Charles Lawson, and Gloire de Dijon had as much pink as buff about it. The first two or three blooms of John Hopper came true to character, but those that followed were of one shade of colour, deep carmine. Duchesse de Cambacères was striped, and Jules Margottin had the colour nearly bleached out of it.

King's Acre, about which I ventured to express a favourable opinion in a former letter, like many others in my collection, did not open well, which I much regretted, as I intended to have sent a bloom or two to the office of this Journal. It has an immense bud and great depth of petal. Had the season been favourable I feel certain that it would have made some of the more highly-favoured varieties around it look poor in comparison.

The whole of my Roses were, more or less, affected by the cutting winds before mentioned, but from the following I had some fair blooms:—Anna Alexieff, Baronne Prevost, Baronne Hallez, Charles Lefebvre, Colonel de Rougemont, Comtesse de Chabrillant, Duc de Bassano (fine colour), Empéreur de Maroc, Général Jacqueminot, Gloire de Santenay, John Hopper, Lord Raglan (first few blooms large and fine), Souvenir de Leveson Gower, Monsieur de Montigny, William Griffith, Mrs. Bosanquet, Gloire de Dijon, Celine Forestier (extra fine), Triomphe de Rennes (this variety, like Gloire de Dijon, was in a few of its blooms mottled with pink), Charles Lawson, and Kean. I have many other varieties, but the majority of them were most pitiful-looking objects, so far as their flowers were concerned.

In conclusion, allow me to thank Mr. Kent for his letter at page 46, more especially that portion of it regarding the unpronounceable names given to Roses by the French raisers. I am not aware that it is absolutely necessary for a person to have a thorough knowledge of the French language in order to be a good Rose-grower, but it would certainly make everything connected with the cultivation of our favourites much more agreeable were names given which the generality of people could pronounce. Perhaps some of our eminent nurserymen may be induced to take pity on us, and give the English pronunciation of the French names in the next editions of their catalogues; I feel sure that a large number of their customers would not only be very willing to pay for such a catalogue, but would hail its publication as a boon.—Loch Ness.

Okeford Fitzpaine, Dorset.—The Rose plants here stood the first frost well, but they have in some instances suffered severely from the last one. I do not think that more than four or five are absolutely dead, but there are many of the hardiest Roses skin-blackened, and, what is remarkable, the wood of last year is less discoloured than that of preceding years. I have dug up one or two of the ground plants most smitten, and I find that they are sound in root and wood beneath the mulching and snow-line. The few standards here have borne the severe weather remarkably well. Our leader, the Rev. S. Reynolds Hole, sent me, as a *souvenir*, twelve half-standards of his own budding, which have escaped uninjured. The same may be said of Mr. W. Paul's kind present of seedlings on Briars—namely, two plants of Dr. Lindley, two of Black Prince, one of Globosa, two of Lady Suffield, and a purchased Souvenir de Dr. Jamain. They are evidently hardy Roses. I have no other standards except those fine Tea-scented Noisettes, Triomphe de Rennes, Celine Forestier, Gloire de Dijon, and Maréchal Niel. These withstood the first frost well, with only a little litter over their roots; but when the second frost set in, I tied up all my Yellow Roses (about fifty-six—famous specimens), wholly with straw. Here straw is scarce, otherwise I should have wholly tied up every Rose of all kinds. Every Rose, however, has been littered twice, and I think that I shall come off as well as most people; still many fine plants will have to be cut down, wholly or in part, to the snow-line.

I have had dismal accounts from Yorkshire. Mr. Taylor, of Bedale says—"I lost two thousand standards in 1860; and I do not think one in thirty of two thousand standards will recover. The Manetti Roses are dead to the snow-line, but will spring up again. Henceforth I am all for Manetti." He has found out two truths which I told him years ago—viz., "You will become sick of propagating heaps of untried novelties, and you will adopt ground plants in preference to standards, as they are more easily defended."

I consider that the frost of this year has been more severe than in 1860, though not so lasting. In 1860 the winter succeeded the summer without an autumn. Had such been the case this year, I do not think a vestige of a Rose would have been left. A genial spring and autumn are merciful interpositions between summer and winter, and *vice versâ*.

Such a severe frost as we have had is a good test of the constitution and toughness of Rose plants. The following Roses of the newer kinds have withstood the frost well, with no other protection than litter over their roots. Some have been cut to the snow-line, but these are quite uninjured—namely, King's Acre, Rev. H. Dombrain, Souvenir de W. Wood, Madame C. Verdier, Duchesse de Medina Cœli, Marguerite Bonnet, Dr. Andry, W. Bull, J. Keynes, Duke of Wellington, Rushton Radclyffe, Achille Gonod, George Prince, Duchesse de Caylus, and Marguerite de St. Amand. Not a Rose here has withstood the weather better than King's Acre.

I did not see the foregoing Roses here last year owing to removal, but I hope to prove them fully this year. Much has been said about the growth and constitution of Rushton Radclyffe. I pointed out a plant of it to "D.," of Deal, when here, and I have examined it since the last two severe frosts, and I cannot see a stain in its skin. I have never found it a bad grower or tender; and I have never yet seen a defective bloom of it. I have at any rate bought twelve more plants, which is a test of sincerity.

So many bad Roses have been dedicated to the English that one cannot be surprised that a good Rose should elicit severe criticism. No doubt there are many inferior Roses "edited" every year, but the following varieties will be found to do credit to their year—namely, Duchesse de Caylus, Rushton Radclyffe, Marguerite de St. Amand, Duke of Wellington, Madame Moreau, and Mdlle. Amélie Halphen. I have not placed them in the order of merit. Time will do that for me.

I must not close without thanking my friend "D.," for noticing so humble an individual and his retired residence, at which I shall hope to see him in the Rose and Strawberry season; also, my friend, Mr. Kent (who promises me a visit), for his many good Rose observations, with one immaterial abatement—namely, that I do not think that "*Rosier Hybride Remontante*," however well understood by the French, would be as well understood by the English generally as Hybrid Perpetual. The late Dr. Lindley told me, "No one but a gardener could translate gardening French." Hybrid Perpetual, though we understand the class to which we restrict it, is equally applicable to Tea-scented Roses—a noble class.—W. F. Radclyffe.

Cheshire.—On the 1st of January we had 4° of frost in a small greenhouse till seven or eight o'clock at night, everything being very dry at the time, and consequently there was little or no damage. In earth pits covered with glass and one mat, besides an inch or two of snow till the frost ended on the 22nd, yellow Calceolarias and Gazanias seem unhurt. Roses do not appear to be much the worse. They are not nearly so much injured as they were in 1860-61. Portugal Laurels are none the worse, whilst in that winter many were killed down to the ground. Escallonia macrantha seems very much injured, the leaves being very brown; I may say the same of Buddlea globosa; indeed, I am afraid this is quite killed. There are some deciduous shrubs here, I cannot ascertain how they are at present. Arbor Vitæ and Rhododendrons do not appear to be injured. I am sorry I cannot positively state the lowest degree of cold here, but we have scarcely ever been without snow more or less since the frost commenced. The snow is a great protection. All the Broccolis and Savoys are very much injured, and many are killed.—A. B.

Castle Carey, Somerset.—The following are the readings of the thermometer here on the undermentioned dates:—January 3rd, 9°; 4th, 0°; 5th, 12°. Then the thaw came, and the temperature rose as high as 47° on the nights of the 8th and 9th. The second frost commenced on the 11th, 27°; 12th, 18°; 13th, 3°; 14th, 5°; 15th, 8°; 16th, 21°; 17th, 22°; 18th, 22°; 19th, 19°; 20th, 24°; 21st, 23°; 22nd, 22°; 23rd, 27°, and on the following night it rose to 47°. The thermometer is one of Negretti and Zambra's, and is hung 4½ feet from the ground in an unwalled garden. A Deodar has turned quite brown; all Cabbages, except Brussels Sprouts, have been killed or nearly so, and some fine Pampas Grass is quite white, whether killed or no I can hardly tell.—G. T.

Middlesborough-on-Tees, Yorkshire.—I send you the names of a few plants I noticed in flower in this locality between the two winters we have had, which have been very severe. Vegetation has suffered very much. In our garden most of the Cauliflowers and Broccolis have been killed; Savoys, Curled Kale; Early Sprouting, Lee's White Sprouting, and Snow's Winter Broccoli, are for the most part killed. Cottagers' Kale and Brussels Sprouts have endured the frost pretty well. Endive, Lettuces, Onions, and the other occupants of the garden have been injured very much. Shrubs,

too, have suffered. Sweet Bays, Laurustinuses, Aucubas, and Cotoneasters are killed down, whilst Laurels, Hollies, and many others present the appearance of having been scorched. Most of the tender kinds of Roses have been killed to the ground, and the others have suffered very much. Plants in flower January 8th.—Double Daisy, double Primrose, single Primrose, Wallflower, Garden Anemone, Yellow Jasmine, Winter Aconite.

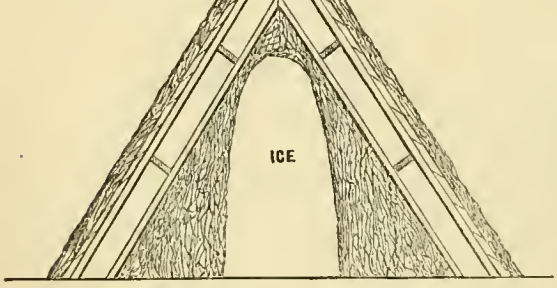
ICE-KEEPING.

The excellent advice recently given on this subject by Mr. Short, whom I have known many years, and on whom may be placed great reliance, deserves the particular attention of all who are in any way interested in storing this most useful article, and although the plan recommended by Mr. Short is not new, it is one which is not generally practised.

Last year I recommended a sort of machine or crusher, and Mr. Short entertains the same view as I had—viz., to obtain, if possible, one solid mass of ice, and to avoid having such a number of cavities as there inevitably must be when ice is stored in lumps about the size of brick-ends, the cavities between which contain an immense body of air, which, ultimately, makes sad havoc with the good-keeping of the ice. I have no doubt but that an ice-grinder will be brought into use at some future day, and at present Mr. Short's plan is the nearest approach to the object I had in view.

We always, if sufficient ice can be secured, make a large stack, independently of the ice-house. We have made one this year, and, taking a leaf out of Mr. Short's book, we have used more snow than we have done hitherto. Indeed, to build an ice-heap without snow, when it can be obtained, is something like a bricklayer putting bricks together without mortar. A fair-sized stack, if well secured, will last till late in summer, and through the kindness of my employer, the ice from one has been the means of saving the lives of many suffering fellow creatures.

To insure a stack of ice lasting a considerable time, we put on two layers of thatch, the first on the ice, and the other on a rough framework, made of fir poles and slabs, as in the accompanying engraving. It takes about thirteen poles for the inside and a like number on the outside. On the latter, thin slabs are placed in a horizontal direction, on which the outer thatch is placed. To keep the outside poles a sufficient distance from the inner ones, short pieces of wood, about 9 inches or a foot long, are fastened between them. The body of air between the two coats of thatch contributes greatly towards the safe-keeping of the ice.



We generally have to put new ice on the top of the old in the ice-house, all of which is snugly covered with straw. Now, it is an old saying that we should let well alone—that is, in this case, if sufficient ice is preserved for the family, why trouble about any fresh plan? and we feel afraid to try any other method, fearing success might not attend our efforts; but I must confess that I am not particularly fond of straw, and if it is not indispensable, a much greater quantity of ice could be stored in any house, and the ice would be saved from the pernicious effects arising from its being surrounded with wet straw, which could be saved for a more appropriate use. If some of the great ice-preservers in this country would state their opinions as to whether ice can be preserved without straw, it would be a great boon to many. Mr. Short did not state whether he used straw or not, but he informed us that we should have plenty of ice in January, and sure enough his prediction was true to the letter.—J. Perkins, *Thornham, Suffolk.*

PEACH TREES FAILING IN A PEACH-HOUSE.

Last spring some of the trees showed nothing but fruit-buds, except at the points of the shoots, and a good many of them had died back in the autumn. Can you tell me what is the cause of the shoots dying back and the buds dropping off in spring? also, why the fruit dropped off before they were properly ripe, having their stones split through the middle, and showing signs of decay? The border has a concrete bottom, and is filled up with 3 feet of soil of a clayey texture. Water is always given when necessary. The trees are beginning to drop their buds this year again.—Grampian.

[When some kinds of Peach trees, as the Noblesse, are becoming past their best, and feeling the effects of heavy cropping, the most of the buds on a shoot will be fruit-buds, and the wood-buds will be chiefly confined to terminal ones. When it is necessary to keep these shoots short and near home it is best to stop early in summer, and thus obtain another leader. When that is not done, such shoots left growing all summer, and with a prominent terminal bud, should not be stopped at all in spring-pruning. Such trees will be distinguished by only one fruit-bud, and sometimes two in a place along the shoot. Younger and healthier trees will have triple buds, of which the central one is generally a wood-bud. By pruning accordingly, we have had fine crops and fine fruit from old trees. The dropping of the buds is generally the result of roots too dry or too much soaked. When the dropping is in moderation it saves thinning afterwards.]

WORK FOR THE WEEK.

KITCHEN GARDEN.

The general preparation of ground for the spring crops having been delayed beyond the usual time, the requisite digging and trenching should be at once performed, preparatory to a more thorough manipulation of the soil before sowing-time. The principal causes of success in growing vegetables are a fine tilth, and as great a depth of earth as can be obtained, without interfering with the subsoil, if the latter is of a sour nature. Clayey and retentive subsoils should, however, be forked over, loosening the ground for some depth. This will facilitate the passage of water from the roots, and by degrees the subsoil will improve. There are but few vegetables which do not require a medium depth of 2 feet to grow in, some more; hence the necessity of deep, well-pulverised soil for their successful cultivation. It is often, too, a rule to put the manure in when digging in trenches; this is a bad system. To be effective, the manure should be completely mixed with the soil to its full depth. For the present, therefore, the dung may be dug in in the process of trenching, and its thorough incorporation with the soil will be best effected when the ground is again worked over with a three-pronged fork. Respecting the application of manures to different soils, I may observe that for warm, dry, soils such as are of a cool nature, as cow and pig manure, should be applied. Horsedung will answer best on medium loams, while on stiff, clayey soils a portion of ashes, road-scrapings, old mortar, or refuse of any kind, may be used in addition to ordinary manure. They will help to keep the land porous, and, consequently, assist the roots of growing crops to permeate the mass of soil. Old Cabbage ground which has been under Sprouts since last August, will now become available for other purposes. Where plenty of *Coleworts* have been provided, some of the latest of the July sowings will supply their place, and stand over for early Cabbage. Old Cabbage ground should be trenched and pretty well manured, as Cabbage is a scourging crop. It is generally followed by a second sowing of Peas, the Peas in their turn succeeded by Celery-beds, and this course prepares again for any of the Brassica tribe. Some good beds of Horn *Carrots* may be sown directly, sprinkling a little *Radish* seed with them. *Cauliflowers* may be turned out of their pots from the cold frames, putting four strong plants under each hand-light. See that spring-sown Cauliflowers do not "draw," if raised in heat; let them be pricked out betimes. Let the *Peas* or Beans sown in boxes be hardened off by degrees in the cold frames preparatory to transplanting. A good breadth of *Broad Beans*

should be planted; for the main crop the Green Longpod will be found very useful. A portion of the *Celery* may be taken up to check "running," and laid in by the heels very deep. Let a bed or two of Celery be sown directly on heat; also of Portugal or Tripoli *Onion* intended to be grown to a good size. *Spinach*, Round should shortly be sown on a warm border, and a little *Parsley*.

FRUIT GARDEN.

Proceed without delay with all pruning, nailing, training, and planting. Apricots and Figs may, however, be pruned when the bearing wood can be distinguished. The nailing of Plums, Pears, and Cherries, ought to be forwarded at all favourable opportunities. At this time a commencement may also be made with Peach and Nectarine trees. It is a good practice to wait till the buds begin to swell a little, as too early pruning only hastens that event, which is not desirable in our fickle springs; by disbudding all superfluous shoots in summer, the knife has very little to do except in shortening the shoots.

FLOWER GARDEN.

Every arrangement should now be made for planting Ranunculuses. Prepare the tubers for planting by removing all small ones. These should be immediately planted by themselves, as but few will flower in the coming season; they will gather strength and size for the next. As the present is the season when the mosses attain their greatest perfection, it will be found the best time to eradicate them; a sharp-toothed iron rake or light drag will be the best implement for this purpose, working it sufficiently to bring up the moss, which should be cleared off and the lawn left for some time, when a second operation may, perhaps, be necessary. In March, sow thickly Sheep's Fescue Grass and Crested Dog's-tail, and apply a dressing of lime rubbish sifted and fresh soil, or the latter and fine bone dust, which, with occasional rollings to keep the land firm, will soon produce a good sward.

GREENHOUSE AND CONSERVATORY.

Now we have sunshine once more, a slight advance may be allowed in the atmospheric heat, especially on bright days, remembering that in proportion as we advance in heat so must we in atmospheric moisture and a free circulation of air. In addition to keeping the conservatory gay with blooming plants, let the arrangement of the interior be occasionally changed by grouping the plants somewhat differently, and adding a few striking ones, as some of the hardiest Palms, for effect.

STOVE.

The plants here will now require an increased amount of atmospheric moisture with a slight advance in heat. I prefer all such advances for the most part on the afternoons of bright days, when solar heat may be enclosed early, and with it a moist and wholesome atmosphere. Begin to repot Orchids, taking them exactly in the order in which they bud; be sure that your material is scalded or half charred to destroy insects. Keep the plants well elevated, and use plenty of charcoal in lumps of considerable size, fastening the whole at last so that the plants cannot be loosened by agitation. Sphagnum or other moss pegged on the top makes a good finish, and is to be recommended in houses which are unavoidably deficient of atmospheric moisture. Syringe plants on blocks occasionally. Keep a sharp eye on insect baits at this period.

FORCING-PIT.

Follow up a proper succession of the plants named in former calendars. Take care to maintain a circulation in the atmosphere as often as the heat will permit. This secured, use abundance of atmospheric moisture, especially in the afternoon and evening.

COLD PITS.

Having now turned our back on, I should hope, the severest part of the winter, one of the first acts in spring should be, to use a commercial phrase, "taking stock." Some havoc will be found both in the flower garden and in the culinary department, and steps should be taken without a moment's delay to recover lost ground. The cold pits or frames containing stores of half-hardy plants should be closely examined. Most of our best cultivators of half-hardy flowers for the modern improved massing system lay in their stock by propagation during July and August of the preceding year. Among these, in the majority of cases, will be found blanks, and some of the best store pots or established plants should be introduced into heat in order to procure early cuttings. No delay can be permitted in this matter, for much of the success in massing depends on having plenty of forward, well-established, and well-hardened plants at bedding-out time.—W. KEANE.

DOINGS OF THE LAST WEEK.

THOUGH our stiff ground is still very wet, took the opportunity of trenching and leaving rough-ridged any ground now uncropped, as that lately occupied by Celery. Cleared off for the same object of trenching, two pieces of Turnips in good condition, that were transplanted last autumn, and which were not at all injured by the frost, owing to the slight covering of snow. These Turnips were placed in a heap in a shady position, and a little litter thrown over them, and they will keep sound and crisp much later in the spring than if they had been left growing in the ground.

Storing Turnips.—The neatest, and seemingly the most workman-like mode of doing this is not always the best. We shall presume that in either case the Turnips are put away before they are injured by frost. We have sometimes noticed, when nice dry Turnips and Mangolds have been carefully built in large round heaps, or in long, span heaps, thatched and earthed, with straw wisps, or wooden openings left for air, that, nevertheless, the roots had heated and grown prematurely, and been taken out much injured, many being decayed and rotten, whilst from other heaps, and especially in the case of Turnips, when thrown carelessly together to a depth of 2 feet, or less, and merely a little litter strewed over them to keep out severe frost, they would come out as fresh and as juicy as when they were thus placed in a heap. If the rains should pass through to the heaps, and these were not deeper than those referred to, the roots would not suffer in consequence. It is as well to keep Mangolds dry, as if wet a little frost injures them.

There is little doubt that we often injure by mistaken kindness. We had a piece of fine Endive in an earth-pit, over which we put some old patchy sashes, as the weather became severe, and threw some litter over the sashes when the cold was greatest. The position was unfavourable to the Endive, the autumn being so wet, and though we had a pretty fair supply, the Endive would not have kept, if we had been never so anxious, as it (the Batavian) has done in front of a south wall with merely a little rough hay shaken over it in a few of the coldest nights, and where it is now green and healthy. We have had the same sort standing out of doors all winter, each row planted on a slightly elevated ridge (and consequently, there was a valley between every two rows), with but little or no protection, while those coddled in frames suffered from damp. Lettuces in frames over old hotbeds, required a considerable thickness of litter over the glass to keep them fit for use, whilst a lot, pretty forward, in an open orchard-house was kept quite healthy with a mere sprinkling of litter, and that because the atmosphere of the house was so much more open and dry than that of the frame.

Sowed Early Horn Carrots, with Radishes between, over a hotbed; thinned the smallest from the first Radish-bed to give more room for those that will soon be fit to pull, the present supply coming from an earth-pit protected all the winter by old sashes and a covering of litter in severe weather; filled another light with Asparagus, the last filled just appearing whilst the first bed is about over. Sowed Tom Thumb Peas in pots to fruit there, and Dillistone's Early in semicircular drain-tiles, to produce under protection; and will sow Sangster's, &c., in turf for transplanting in the open air in a week or two, as sowing out of doors is of no use with so many eyes looking after the seed to feed as many mouths. Turned out a lot of Potatoes from small pots into producing pots, put a number more of Ashleaf and Veitch's Early into small pots, to be transplanted into beds, where they can have protection, and will start others ere long to go out of doors. Our seed Potatoes have not kept well this season, having suffered much from disease, though they were housed in good order, a fine sample then, and kept cool ever since. Put in successions of Sea-kale, Rhubarb, &c., and sowed Celery and other things in heat. Repotted Cucumber plants which have put on a fine green livery since we have had a little sun. Finished a hotbed for a frame, put the earth in the centre, covered all over with soil, and hope to plant out in a few days, as we like to have the dung-frame and the hot-water pit to have a race with each other, and they generally prove pretty equal antagonists after this time, when litter can be had to bank up the frame. Planted out in a pit three lights of Dwarf Kidney Beans, from small pots, to succeed those now in pots, as after this time planting-out saves much labour in watering, though nothing does better in pots; but now we shall want almost every pot to be at liberty for other purposes.

The first piece of Mushroom-bed in the Mushroom-house

has fortunately done us good service, and the third piece has been spawned and earthed over, the earth having stood in the Mushroom-house in barrows for a couple of days to become heated before being used. For a few nights we were troubled with some huge snails, that would clear off all the inner parts of several large Mushrooms in a night. We fear they were introduced into the house with the ball of soil round Rhubarb roots. We have seen no more signs of their presence lately. We know of no means of getting rid of them except searching with a candle at night. They generally keep out of sight during the day. They are less easily enticed with greased Cabbage leaves or brewers' grains than slugs.

FRUIT DEPARTMENT.

Looked over the fruit-room. Some kinds of fruit have gone considerably within eight days, and that from no effects of frost. Sowed Melons in the bed prepared for Cucumbers. Though seedlings do well enough raised in heat from flues or hot water, we have it may be a prejudice for raising them in the heat from fermenting material. We find it is of no use sowing such seed, unless protected from mice. No better plan for sowing such seeds can well be adopted than sowing in pots, 2½ inches down from the rim, covering with a square of glass, and placing something heavy on the glass to prevent its being moved.

Strawberry Forcing.—The plants in bloom are looking much better and stronger since the change in the weather. Those set on the top of a firmly trodden bed in a pit, yielding just the slightest heat at the bottom, are looking well, but a part will have to be moved, and the bed made to the right level, so that the pots may stand at the right distance from the glass. At this season we would have preferred temporary wooden shelves or a regular stage for the purpose, but in gardening much must be done by makeshifts, though it is always better to be able to dispense with them, as most makeshifts, if they save in material, greatly increase the labour. We had two shelves for Strawberries in the Peach-house, but we wanted another near the front, where the sloping roof terminated on the wall-plate, about 18 inches above the inside border. There being no wood for a shelf to be obtained, but some round iron rods that had formed part of a fence being at liberty, pots of the requisite height were set bottom upwards, a brick placed on the top of the pots to give more bearing room, and three of these rods laid along on the top of the bricks. A turf 9 inches wide, and 1 inch thick, was then laid along the rods, grass side downwards, a little leaf mould sprinkled over the turf to make all level, and on this the row of pots was placed, and no better home could be given them. We have used such rails for shelves suspended from rafters, but we object to their greater weight for such purposes.

One advantage of thus setting the pots on turf is, that there is little likelihood of their being over-watered. Early Strawberry plants are often greatly injured by water standing in the saucers when the plants on shelves stand in these, and they must do so often to prevent the drip falling on other things. Hence the importance of the saucers raised in the centre invented by Mr. Ingram, of Belvoir Castle, as though water may stand in the saucer, the bottom of the pot will not be in the water. We have often gained the same object in a much more clumsy way, by placing crocks, &c., in the middle of the saucer for the pots to stand on. Without such contrivances, and where a little drip is of no consequence, we prefer turf or moss to saucers on shelves, but where neatness and effectiveness are to be combined commend us to Mr. Ingram's saucers.

ORNAMENTAL DEPARTMENT.

After the frost it was necessary to go round the walks, sweep them, and remove from the grass any bits of gravel that had been swept over with the snow, when brushed from the walks. Cleared off wood and a few leaves from the lawn, and rolled with the light wooden roller, which gave it a level and green appearance. We will have the beds and borders dug and freshened as soon as possible.

During several dry, frosty days, pruning shrubs and cutting Laurels was proceeded with, as we find in many places that to keep Laurels healthy to their bases, and to prevent their becoming sickly at their points, they require frequent shortening. These prunings come in valuable for many purposes of sheltering crops, and when laid in heaps, and trodden firmly in the course of the summer, and especially if left to another year, nice stakes can be obtained for many purposes, and what is not used for these and firing, will go to the charring and burning heap.

The conservatory was fresh arranged, and Cinerarias and some other plants in bloom taken from the Peach-house, &c., the greater number of plants being moved from thence to the late vinery, so as to afford room for Strawberries on shelves, and to set at liberty the floor for bringing on the Potatoes and Peas already referred to. Much work was also done in shaking out and repotting Fuchsias, placing them at the back of the vineries, potting Pelargoniums in their blooming-pots, and setting them at present on a stage in the second vinery, potting young plants for succession, and preparing to give more room to Scarlet Pelargoniums for pots and beds. Afforded more room and a more airy position to double Pruuus, and Deutzias in bloom. The change in the weather will tell beneficially on all forced shrubs and bulbs. For general management see previous Numbers.

Accumulated Heat.—This matter (see pages 81 and 82), is of great general and gardening importance. Mansions have been burned down because large beams abutted on a kitchen chimney. Other houses have been saved because the evil was found out in time. Two years ago, against remonstrance, the hearthstone of a fine upper room was formed, not of a stone, as in Mr. Pearson's case, but of small flooring tiles, with, of course, the joists and rubbish, and lath and plaster beneath them. Like the glazier smashing windows, such a plan might be good for trade, because so conducive to a conflagration. The case of the hotbed heated by a flue is also suggestive. We helped many years ago to manage a long Pine-pit, heated in a similar way by strong flues, with a floor of strong slabs fully 20 inches above the flues, and no plan could have answered better, and we never heard of any accident; but then there were wooden funnels on each side to let the heat from the chamber into the atmosphere of the pit, and consequently the heat from the flues would not accumulate solely in the chamber. There is yet something to be learned about heating in close chambers. In this case dry heat may so accumulate as to result in burning, and in some other cases we have found, that with plenty of heat in the heating medium, bottom heat above the chamber could not be sufficiently obtained until there was just as much of an opening into the chamber as would prevent the air there being quite still and isolated.—R. F.

COVENT GARDEN MARKET.—February 6.

A marked increase in our supplies generally, particularly of Pines and hothouse Grapes, the demand for the latter falling far short of the supply. French imports as usual. Cornish Broccoli has much improved during the past week. The best samples of Potatoes have again advanced in price.

TRADE CATALOGUES RECEIVED.

E. G. Henderson & Son, Wellington Road, St. John's Wood, London, N.W.—*Catalogue of Flower, Vegetable, and Agricultural Seeds.*

W. Armitage & Son, 4, New Street, Huddersfield.—*Catalogue of Flower Seeds.—Catalogue of Vegetable and Agricultural Seeds.*

TO CORRESPONDENTS.

*** We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed *solely* to *The Editors of the Journal of Horticulture, &c.*, 171, *Fleet Street, London, E.C.*

N.B.—Many questions must remain unanswered until next week.

"The Mulberry is Wiser than the Peach" (*F. T. B.*).—This proverb has been versified as follows: -

"The Peach tree, with too eager haste
To show its blossoms to the sun,
Gives its pretty bloom to waste
Before the frosts of spring are done.

"Much wiser is the Mulberry,
Which only thinks its leaves to show
When leaves are green on ev'ry tree,
And Roses have begun to blow.

"They most ensure success and praise
Who, guided by the rule of reason,
Do fitting things on fitting days,
And dress as most becomes the season."

Potatoes—Early Ross (*J. M. O.*).—It might be obtained from some seedsman in Scotland. We do not know it here.

Dissolving Bones (*J. P. Gravel*).—To form superphosphate of lime the proportions are 1 lb. of bones, 12 ozs. of sulphuric acid, and 12 ozs. of water.

Soap-suds as a Manure (*P. B.*).—If Dr. Dresser stated in his lecture that soap-suds not only are not fertilising, but are "a deadly poison" to fruit trees, he made a great mistake.

Working Plans of Greenhouses (*Handy Man*).—It is quite impossible for us to furnish them. Nothing is more easy than to show a local carpenter the kind of house you need, and ask him to send a detailed estimate.

Verbenas in Frame Mildewed (*V. S.*).—The shoot was much affected with mildew. No amount of tobacco smoke will destroy it. You must dust the spots on the leaves and stem with flowers of sulphur through a thin muslin bag; apply the sulphur to the under as well as the upper surface of the leaves. This and more air will effect a cure. We do not observe any trace of thrips, therefore discontinue the tobacco fumigation.

Muscat Hamburgh Grapes Cracking (*A. B.*).—Your house must have been kept close and moist. The cracking is easily accounted for by the attack of mildew, on the first appearance of which you should have dusted the affected parts with flowers of sulphur. The fact of your house not being heated renders it difficult to keep its atmosphere dry when the fruit is ripening; but you may do much by giving air early and shutting up early, affording, however, a little ventilation at night. The outside border will be unfavourable to the ripening of the fruit, particularly if the weather be wet. We do not consider the Muscat Hamburgh a suitable Grape for planting in cool houses having outside borders.

Summer-pruning Peach Trees (*W. C.*).—The shoots stopped at the third leaf, if the laterals produced upon them during the summer are stopped at the first leaf, will not require any pruning in winter, as they will for the most part be so many clusters of spurs and fruit-buds, and to cut them in would be to sacrifice the crop. Any, however, which are very long may be shortened to within an inch of their base. The shoots left at 9 inches apart to cover the wall are not to be shortened, except to cause the production of sufficient shoots to cover the wall at the above distance apart. They may in that case be shortened at the winter pruning to half or two-thirds of their length, as may be necessary. We cannot name plants from mere leaves.

Plants for Shaded Border (*A Subscriber*).—You say "the south side of garden under the 10 feet-high wall, consequently shaded by the wall." We conclude it is to the north of the wall, and, if so, the plants are few that will grow in such situations. Vinca major and minor, and London Pride, are about the only plants that would thrive near the wall, though at some distance from it Primulas, Auriculas, Pinks, Sweet Williams, Stocks, and most herbaceous plants would succeed tolerably well. If, on the other hand, the border is to the south of the wall, it would answer admirably for early-flowering bulbs and plants, as Snowdrops, Winter Aconites, Crocuses, Tulips, and Hepaticas, succeeded by bedding plants, as Pelargoniums, Lobelias, Calceolarias, and many others, as well as Stocks, Asters, and various annuals.

Laxton's Pea (*Amateur*).—As Messrs. Carter's observations appeared in the columns of another Journal, it is in those columns your further comments should be inserted.

Man Traps (*J. F. S.*).—It is not legal to set them either in a walled or unwalled garden. Blanche Superbe and Louis Philippe are Rhododendrons that would suit you; but if you write to any nurseryman and tell him what you need, he would supply you.

Culture of Ferns (*Major C. H.*).—"The Fern Manual" contains what you require. If you enclose sixty-four postage stamps with your address you can have it free by post from our office.

Book (*Fred*.—Henfrey's "Structural and Physiological Botany" will suit you. A botanist's dissecting microscope may be purchased for a guinea.

Pit Perfectly Shaded (*B. H.*).—No plant will thrive in such a sunless situation except some of the Ferns. We advise you not to heat so small a structure, but to be content with hardy Ferns. Any of these will grow in your pit.

Our Journal (*H. H.*).—You ought to receive it on Friday. We publish now on Thursday morning. We cannot insure a copy not to be delayed by the Post Office. If it frequently occurs, write a complaint to the Secretary, General Post Office, St. Martin's-le-Grand, London. He will give the local postmasters a wigging.

Apples for North of Ireland (*A. F. K.*).—We have no doubt that Blenheim Orange and Coe's Golden Drop will ripen in your district.

Trained Trees (*T. P. F.*).—The plate in Kennett's "Parochial Antiquities" merely represents evergreens trained round arched recesses in the front of Sir John Walter's house.

Substitute for Cloth Shreds.—We are gratified to find the very excellent substitution of india-rubber cloth for the old-fashioned and harsh cloth shreds is likely to be generally adopted. We observe the notice of this article (Journal of Horticulture, page 90). The same idea was suggested to us some months since by that eminent horticulturist, Dr. Wallace, of Ballymena, Ireland, and as we felt thoroughly convinced of its efficacy, we decided upon introducing it. Being offered in convenient quantities for large or small requirements, we doubt not it will soon entirely supersede the old shred.—James Carter & Co.

Training Peach Trees in a House (*E. S.*).—We do not advise the covering of the back wall of your vinery, 35 feet by 12 feet, with Peach trees, for unless the Vines be more than the usual distance apart the Peach trees, though they may grow well, will seldom, if ever, produce a crop. The case will be different if the Vines are 5 or 6 feet apart; enough light may then reach the back wall for the well ripening of the wood and perfection of the buds of the Peach trees. If the Vines are a less distance apart we would advise the Peach trees to be grown in pots as pyramids or bushes, and to be set in the intervals between the Vines, so as to afford them all the light possible. If you plant the Peach trees against the back wall, the shoots should not be trained upright, as shown in your letter, as the lower parts of the branches will soon become naked. Instead of training the shoots upright, bring them down to an angle of 45°, and cover the wall with shoots 9 inches apart in diagonal cordons. The laterals, or side shoots, if they grow more than an inch, are to be pinched at the third leaf, but any short stubby shoots are not to be interfered with under any circumstances. The shoots once stopped are throughout the season of their production to be pinched at the first leaf after the first stopping. The leader must be allowed to grow, and it need not be stopped or pruned back at the winter pruning, but bent down to an angle of 45°, and it will break throughout its length. Any laterals upon it should be pinched at the first leaf throughout. The laterals, at the winter pruning, if more than 3 inches long, may be cut back to a wood-bud, and if it be surrounded by fruit-buds all the better. The Peach will not bear the same pruning and spurring as Vines.

Acacia platyptera after Blooming (*J. D.*).—The weak and dying wood should be cut clean out, and any long straggling shoots cut back, so as to promote the formation of a compact head or plant. When the young shoots are an inch or two long, the plant should be repotted, carefully removing the old soil, or as much of it as possible, without destroying or injuring the fibres. Do not give a large shift, drain the pot well, and over the drainage place an inch or two of the rougher parts of the compost, which may consist of two-thirds turfy loam, one-third sandy peat, and one-sixth of silver sand. Keep the soil moist, but be careful not to over-water, and keep close and shaded for a few days until the roots are working in the fresh soil.

Lilium lancifolium rubrum (*Idem*).—The top-dressing should at once be removed, also the offsets. Look to the drainage of the pots, remove as much of the old soil as can be done without injuring the roots, and replace it with fresh, some of the coarsest being placed over the drainage. The top-dressing must be repeated when the shoots are a few inches above the rim of the pot.

Pine Apples (*W. C. W.*).—The three we like best are the Queen, Smooth-leaved Cayenne, and Black Jamaica, and we grow one-third Queens in proportion to two-thirds of the other two collectively. They should not have a temperature of less than 55° at night in winter, and fruiting plants should have a night temperature in winter of 60° to 65°. Succession plants will endure a temperature of 45° if the soil and atmosphere are dry, but it is not good for them. The principal propagators of Camellias are the Ghent nurserymen.

Grafting-wax Making—Grafting Hollies (*A Four-years Subscriber*).—A good grafting-wax may be made of Burgundy pitch 8 ozs., resin 8 ozs., bees's wax 4 ozs., and lard 4 ozs. Place the ingredients in a pan, and melt them over a slow fire. It should be used warm. Hollies may be grafted when the plants recommence growth, which will be during April, but the exact time must, of course, depend on the season. It should be done before the buds of the scions begin to swell.

Grape Bunches Becoming Tendrils (*A Subscriber*).—It is mainly to the immature state of the wood that the curling of the bunches is due. The embryo bunches are but imperfectly formed, and the roots we apprehend are in a cold, deep, and wet border, hence the bunches curl up and become tendrils. You can do nothing to prevent this beyond keeping the border as dry as you can in winter, so as to preserve as many of the fibres as possible, that they may collect food for the support of the bunches. In cold wet borders the Vines do little towards the feeding of the bunches at an early season, for the chief fibres perish in winter, and others are not reproduced until the soil has become warmed by the sun's heat. The covering of the border is good, and the material employed for the purpose should be removed early in April. Raising the temperature will not prevent the bunches turning into tendrils, but will increase their tendency to do so. The temperature from the present time up to April should never exceed 40° from fire heat; this will allow the Vines to break naturally. If you commence with the last week in March increase the temperature to 45° the first week, and then 5° fortnightly until you reach 60° at night, which is to be the highest night temperature until the Vines are in flower, when the temperature may be increased to 65° at night until the blooming is past; afterwards keep it at from 60° to 65° at night. You cannot maintain too moist an atmosphere from the swelling of the buds till the Vines flower, when they must not, of course, be syringed, nor can they have too much air, taking care to avoid cold currents. The trough may be filled with clear liquid manure, which is better than rain water. The Vines being old their roots have, no doubt, gone down into bad soil, and far out of the influence of the sun's heat and of air. The only effectual remedy will be to make a new border and plant young Vines. The old Vines are far too old to lift and replant.

Azalea Leaves Falling (*Walmer*).—The Azalea leaves were browned at the tips as if the plants had been heavily syringed, and water allowed to drop or hang from them, or the house may have been kept excessively moist. The foliage at this season should be kept dry, and the atmosphere

also dry by giving abundance of air. The potting in October has led, we presume, to the plants being excessively watered, to the destruction of most of the fibres, and that we think is the cause of the leaves falling, as they are anything but mature. We can only suggest that the plants should be very carefully watered, none being given until the soil becomes dry, and yet not so dry as to cause the foliage to flag, and then give sufficient water to show itself at the bottom of the pots. Give all the air possible, do not syringe the plants until they bloom, and then afford them a light situation.

Gloxinia, Gesnera, and Achimenes Culture (*C. W.*).—All thrive well in a compost of turfy loam, peat, and leaf mould in equal parts, adding sand if the soil require it. It should be sandy. The size of pot for the Gloxinias will depend upon the size of the tubers. Those two, three, or more years old should, in the first instance, have pots twice their diameter, and when they have grown a few inches high, and filled the pots with roots, shift into pots 3 inches more in diameter. The Gesneras, if of the tuberous-rooted kinds, as G. purpurea macrantha, require the same sized pots as Gloxinias; but if of the scaly-rooted kinds, as G. zebrina splendens, they should have pots in proportion to the number of roots put into each. A seven-inch pot may have five tubers, and a 12-inch pot twelve roots. For Achimenes, pots are not so good as pans 8 inches deep, and 1 foot to 1 foot 6 inches wide. The tubers may be placed in these at an inch apart. All require the temperature of a stove—from 60° to 65° by night, and from 70° to 85° by day, or they may be started in a hotbed, and when a few inches high removed to a vinery at work.

Tritonia Planting (*Idem*).—You may plant out these any time after March, hardening them off well previously.

Planting Vines (*A. B. C.*).—We do not perceive the propriety of double-rodding each Vine, nor what you will gain thereby. The case will be different if you have two rods to each Vine and allow a proper distance between them—from 2 to 2½ feet. The Frankenthal is an excellent Grape. Your plan of planting Frankenthal for permanent Vines, and Black Hamburghs between them for fruiting as soon as possible, is anything but advisable, though you may do so and take a heavy crop on the Black Hamburghs the second and third season, and then cut them out; but we are obliged to add that we have tried it, and find the permanent Vines do not make such progress as those not having temporary Vines between them, and in comparison have lost one year in three. On the removal of the temporary Vines, after having borne two heavy crops, many of their roots must remain in the border, and so foster fungi, which, spreading or being in contact with the roots of the permanent Vines, attack and destroy them, rendering the removal of the Vines a work of necessity. This has been the case in those instances of temporary and permanent Vines in one border that have come under our immediate observation. We do not, therefore, advise the planting of permanent and temporary Vines in the same border; but if Grapes are wanted in greater quantities than the cropping of the newly-planted Vines may be allowed to produce, the wisest plan is to grow them on Vines in pots.

Wash for Peach Trees and Wall (*Idem*).—You may form a solution of 8 ozs. of soft soap in a gallon of water, and add thereto a lump of unslaked lime and flowers of sulphur in the proportion of two-thirds lime and one-third sulphur, sufficient to bring it to the consistency of paste, which you may reduce to the thinness of whitewash by adding tobacco water. Such a composition would be excellent for the wall; but for the trees we would reduce it in strength, and besides, we do not see how you will reach the back of the branches next the wall, unless the trees are unnailed. They may be washed with a solution of 6 ozs. of soft soap in a gallon of tobacco water, diluted with six times its volume of water—that is, if the tobacco water from the tobacconist be used, with a sufficiency of sulphur added to bring it to the consistency of paint.

Sowing Rhododendron Seed (*Idem*).—The best way is to place 6 inches of very sandy peat in a frame, so as to bring the surface to within that distance of the glass, level the soil, and sow the seed, just covering it with fine soil. The seed may also be sown in shallow boxes in the same soil, and be placed in a cold frame. From the middle of March to the beginning of April is a good time to sow.

Heating by Gas (*G. K. L.*).—In No. 269 of this Journal, published May 22nd of last year, are described various modes of heating by gas, with a drawing of the apparatus of each. Any one of those modes would do for your small pit.

Conduct of Gardeners (*A Country Vicar*).—We have repeatedly published in our columns under what circumstances—namely, the full consent of their masters—they should give away or exchange plants, cuttings, &c. If you know of any who transgress the rule, we recommend you to inform their employers.

Convolvulus mauritanicus for Edging (*C. T. H.*).—It makes a good edging for vases and rustic baskets; but we have not tried it for edgings to beds, though it thrives in the open ground in our light gravelly soil, and would probably make a good edging. The plants should be 1 foot apart. It is worth a trial, being a very pretty plant.

Trees and Shrubs for Bog Soil (*G. S.*).—The best trees are Alder and Birch; and as for shrubs, we know of none that would thrive in such wet and undrained ground.

Pruning Old Wall Trees (*Idem*).—You can do nothing with trees that have not been pruned for twenty years, beyond cutting out the old wood. The planting of young trees between the old ones is not good, as the permanent old trees will have spread so much from the wall as to shade the young ones and interfere with their growth. If the old trees are worn out or unfruitful we would stub them up, renew the soil, and plant young trees.

Grafting Rhododendrons (*A Lover of Flowers*).—The best time to graft Rhododendrons is towards the end of August or early in September, when the shoots have ripened. The shoots of stock and scion should be of equal thickness, or as nearly so as possible. It is best performed by what is known as side grafting, putting in the grafts near the soil. The head of the stock should be cut off 6 inches above the union, leaving some leaves on it. To this the graft may be tied. After grafting, place and keep in a close, cold frame until the union is complete, which will be the case in six or eight weeks. Then give air and harden off. In spring the part of the stock above the graft may be cut off neatly immediately above the point of union. The grafting may be done in spring just at the time growth commences, but success is not so certain in spring as late in summer.

Dissatisfied Gardener (*Hard Done By*).—You require at least one more active strong assistant, and the fowls will create quite enough work for one man. You might lessen Sunday work by procuring on Saturday what is wanted on Sunday; but some things you must attend to on that day.

Italian Tuberose Culture (*J. V.*).—The roots should be potted in March, singly, in six or seven-inch pots, in a compost of turfy loam, enriched by the addition of one-fourth well-rotted manure, or one-third leaf mould. Peel off the loose outer skins, but not into the quick, and plant them so deeply in the pots that the crowns will be covered with an inch of soil. Any offsets should be removed. If you have a hotbed plunge the pots in it, keep the soil moist, but not wet, until the roots push, then give more water; indeed, they require plentiful supplies of water. Afford abundance of air, and when the stems begin to rise gradually withdraw the pots from the hotbed, and remove them to a light and airy situation in a greenhouse. After potting you may place the roots in a greenhouse, but they will not flower so finely as if they were placed in a hotbed, in consequence of which the pots become filled with roots in a short time, and the plants are considerably advanced for bloom before their removal to the greenhouse. Water well and syringe frequently to prevent injury from red spider.

Cultivating an Acre (*Suffolk*).—If you send thirteen postage stamps with your address you can have free by post "How to Cultivate Two Acres Profitably." It will give you all the information you seek.

Flemish Cherries (*E. C. D.*).—The article you refer to related to the existence or non-existence of trees planted by Henry VIII.'s gardener. Flemish Cherry trees may be had of any nurseryman.

Festoons of Climbing Roses (*Rector*).—One of the simplest and best examples of this work we have seen was at Luton Park, where a series of festoons surround a sort of oval, in the interior of which were beds of dwarf Roses, divided by gravel walks and broad margins of grass, the whole forming a pretty design. The pillars supporting the festoons were about 8 feet high and the same distance apart, and the fall of the festoons about 18 inches, leaving 6 feet clear from the ground, so as to allow room for persons to walk under them without being so high that the Roses could not be gathered when wanted. The pillars were ordinary ash or chestnut poles, with the bark removed, and the part in the soil and a little above it was charred before being inserted in the ground. The poles were about 3 inches in diameter in the middle, or sufficiently stout to withstand the force of the wind when the plants were full grown, and it is better to err on the side of undue strength than in the contrary direction. A simple hoop at the top of the poles will hold a staple, from which a chain or wire may be carried from one to the other. If a chain be thought too expensive a very good substitute may be formed of pieces of rather stout fencing wire, about a foot long, with the ends bent into hooks or loops, and linked together. When covered with Roses such a support looks as well as the most expensive chain. We have seen a much higher series of pillars, but they are long in becoming clothed with the Roses; and to wait ten or more years, as we knew in one instance, where a number of unusually tall Rose pillars were expected to produce an effect, is too long. We may observe that at Linton Park the festoons form the two longest sides of the oval; a broad walk passing lengthwise through the space is spanned by an arch of Roses, the springings of which are of the same height as the pillars alluded to, a short level bar connecting the top of the festoon pillar with the pillar supporting the arch, and thereby forming an agreeable union.

Removing an old Banksian Rose (*Idem*).—You may take it up carefully with as many roots as you can secure, in the beginning of March, cut in the head pretty severely, but not too much, plant it in a flat basket, such as those in which nurserymen pack plants, and place it under glass or in some other warm situation, where it may remain until its future position is ready for it. Its top can be tied up to a stake for the time being, and in that condition it will sustain no injury for some weeks. If its future destination be against a wall, let the collar of the plant be near one side of the basket, so that, if necessary, when it is planted the basket may be buried with it, or at all events that the bottom of the basket may remain if the sides be cut away.

Forcing-house Temperature (*W. J. N.*).—We are well pleased at your success in the forcing of flowers in a "continuous temperature of 70°," which is as high if not higher than that required for any tropical plant we know at this season. We do not recommend a continuous temperature of 70° in the forcing of Roses, Cinerarias, Primulas, Pelargoniums, Hyacinths, and Narcissus, because we find it positively injurious, and we can grow them much finer and have a longer continuance of bloom by having a considerably less temperature. Roses at no time require a higher temperature than from 55° to 60° at night; Cinerarias bloom in a temperature of from 50° to 55°; Primulas in one of 45° to 50°; Pelargoniums do well forced in a temperature of from 50° to 55°, and Hyacinths and Narcissus in one of 50°. All will last longer in bloom if the above temperatures be reduced 5° when the plants come into bloom. On these temperatures you may allow a rise of 5° by day in dull weather, and one of from 10° to 15° with sun and air. With such a temperature as you name you will find the bloom poor, and the plants will become very leggy, and be spoiled for future forcing, which, however, is not of any great moment, as they are seldom used for that purpose in two consecutive years. What you can want with a continuous temperature of 70° for bedding plants we are at a loss to know, unless you wish to force for cuttings, when a heat of 50° would serve your purpose much better. As for Strawberries in such a temperature, we should expect them to prove blind. We anticipate that your plants will soon be attacked by insects, and become drawn, unsightly objects if such a temperature be continued. We would advise it to be lowered 10° within ten days, and 10° in ten days more, or reduce it to 50° at night, which will grow well all the plants you name. Remove the bedding plants as soon as possible after hardening them well to a more suitable temperature.

Flora Londinensis (*A Cockney Gardener*).—You have been misinformed. The book bearing that name was written by Mr Curtis, and is a botanical work in two folio volumes. If you wish to cultivate flowers in-doors, "Window Gardening for the Many" will suit you. You can have it free by post from our office if you enclose ten postage stamps with your address.

Primula Seed (*Mrs. Hendrick*).—You had better write to Mr. Dean, Seedsman, Ealing, London, W.

Zonale Pelargonium Leaves (*J. H. H.*).—They are very inferior in variety and brilliancy of colours to those of many others now so common.

Sorghum tartaricum (*E. B.*).—There is no species so named, and any one attending to suggestions from the same source will be deluded.

Piping for Vinery—Produce of Vines (*H. W.*).—To force a lean-to vinery, 80 feet long, 12 feet wide, and 18 feet high at the back, and 4 feet in front, would require four four-inch pipes to begin, say in February; but for earlier work you would require at least one more. 2, This piping would be most effective if spread over the floor of the house—say four flows and one return. If that were unsuitable, then the next best plan would be to have them all on a level near the front of the house. The pipes will tell more if on the level than if piled above each other. If such a house were in two or three divisions, then the best plan would be to take a flow and return all the length, and take from these the necessary pipes for each division. 3, The best fuel is the best coal, banked up at night with ashes and cinders. This will be the cheapest, too, if there is no waste; but of course all extra heat will be waste, and hence, when depending on others, it is as well to use inferior coal; but a little coal, cinders, and coke, make economical fuel. There will be no difficulty in your man regulating the heat at night when he is used to the furnace and the boiler, and knows how to spply the damper. There would be no occasion for leaving air on now at night; but after the Vines are set a very little at the top would be advisable. 4, A moderate crop would be from 10 lbs. to 12 or 15 lbs. for each Vine of the thirty, if in good order. The depth of the roots will be unfavourable to early forcing. Deep as they are, we would rather keep the frost out of the ground.

Fowls' Dung as a Manure (*A Constant Reader*).—It is one of the most powerful fertilisers. Vines require neither that nor any other stimulating manure. Fowls' dung is much more fitted for making liquid manure for some plants, or as food for Asparagus and other kitchen garden crops.

Apple-tree Branches Sawn off (*A. B.*).—Not only should the edges of the bark be smoothly cut with a sharp knife, but the whole face of the wound should be covered with melted pitch to exclude wet.

Vines in a Vinery (*Constant Reader*).—We approve of Vines being planted inside for several reasons often given, and one of them is, the securing the stems from vermin, for many a fine Vine we have had destroyed by the nibblings of mice and rats; but in your case we decidedly would plant outside, and take the Vines in either above or below the wall-plate, doing it in the latter mode if you do not contemplate taking the Vines out of the house. In such a case, if any of the stems of the Vines outside are not covered, it is best to place the three sides of a wooden box against each Vine, with the wall for a fourth side, and a lid fastened on, so that neither rats nor mice, neither frost nor wet, can reach them, and then with your old sashes for the border you may grow and force them exceedingly well. In your case we would be perfectly satisfied with such a good outside border.

Protecting Rhododendrons (*Amateur*).—For your protecting belt we would recommend a mixture of common Laurels, Lilacs, Philadelphus, and Ribes, with a front of the Rhododendron ponticum, which would come in well with the groups of finer Rhododendrons.

Pincushion-beds (*Idem*).—The centering of the pincushion-beds with a fine plant of Bijou Pelargonium would improve them if they harmonised well. They would suit well with Viola cornuta.

Alkaline Manures for Potatoes (*D., of Headcorn*).—I did not try them for two reasons:—Firstly, I wrote about them and failed to get a reply; secondly, I did not see the cogency of the reasoning which recommended them. I found certain Potatoes in my garden close and waxy, which others said were mealy; but others were all that could be desired. I could not understand that my ground was in fault, for then I should have thought all would have shared alike: hence I did not try the alkalies.—D., *Deal*.

Select Delphiniums (——).—Three good double Delphiniums:—Alepecuroides, Triomphe de Pontoise, Madame Henri Jacotot. Three good single Delphiniums:—Bicolor grandiflorum, Hendersonii, Belladonna.

Names of Plants (*J. D. M.*).—Your Conifer is Thuja occidentalis. (*G. A.*).—We cannot name plants from mere leaves. We ought to have flowers sent to us. (*M. P. D.*).—Excœcaria discolor. (*Mrs. T. F.*).—Nerine pulchella, a native of South Africa. (*A. R. T.*).—1, Helichrysum vestitum; 2, Phœnocoma prolifera. (*Sophia*).—Lastrea dilatata. (*W. S.*).—Specimens insufficient. (*W. J.*)—The pod you received as "Calvary Clover" is a Medicago; but we cannot identify the species from the fragment sent. (*An Old Subscriber*).—The specimens you enclosed are the catkins of the common Alder. They, as well as the leaves and bark, have for ages been used by the Highlanders and others for dying black.

METEOROLOGICAL OBSERVATIONS in the Suburbs of London for the Week ending February 5th.

Date.	Barometer.		Thermometer. Air.		Thermometer. Earth.		Wind.	Rain in inches.	General Remarks.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

THE EFFECTS OF THE SEASON.

Most poultry yards are in arrears. Broody hens are hard to find, eggs are scarce, and there are no chickens yet. It is wonderful how people who ought to know better rail at their fowls if after forty-eight hours they have not shaken off the effects of a month's frost and begun laying. It has been an unusually trying season for poultry; not only has the earth been bound as it were with iron, not only has water been in many places unattainable, not only have combs and toes been frozen, but the fowls have had to eat snow with all their food, and to drink it when melted. This last lays the foundation of many diseases. Snow is a violent purgative to all birds. The good, fat, matronly Wild Duck, with her ample rounded hows, rises and falls on the lake as the little waves heave, happy that she has avoided in her new home the extreme weather that drove her from the north; but the snow comes. Three days are sufficient to make her sharp as the sharpest that ever crossed the Atlantic. The Lark that fattens on two days' rime of the white frost, becomes a "bag of bones" after two days' snow. Partridges suffer, and so do fowls. They cannot lay till they have repaired and replaced that which they lost. As soon as the bones are well covered with flesh, there is something to spare to go to internal formations.

There are few in the present day who do not keep more than one breed. Some are in confinement, and these have less opportunity than the others of obtaining necessaries. They have only that which is given to them, and the most lavish provision that can be made falls far short of that which is necessary, or which nature demands. Nothing expensive is demanded or necessary. Follow nature as closely as you can. If your fowls are shut up where they have no green food, cut large sods of growing grass, let lots of earth adhere to it, and you will not only see them eat the grass and great part of the mould, but they will roll and dust themselves in the powdered earth that remains after the shaking. Have the bottoms of the pens dug up, and left as rough and uneven as possible, scatter some whole corn, and you will see with pleasure how your birds delight in it, and how they find all sorts of good things while seeking the scattered grains. It is not the piling up of food, nor the throwing down of sacks of corn, that constitutes profitable feeding. Attentions like these make combs red, and fill the egg-basket.

RESULTS OF POULTRY-KEEPING.

In accordance with your request, I send you the summary of my poultry journal for the past year.

I have two houses for my poultry, one built against a warm flue for winter accommodation, and one considerably cooler and better ventilated for the summer months. The fowls have a field of about two acres to ramble in, besides a small plantation. I feed them twice a-day, in the morning at 8.30 with wheat, barley, or oats; and in the evening at 4.30, with a warm meal of boiled potatoes and fine middlings. I have another advantage which I think highly conducive to their health—viz., a stream of pure water.

I do not know that anything extraordinary has happened in my yard, except that a Cochin hen laid two eggs in one day on two separate occasions. The first time she laid both the day before and the day after the feat; on the second occasion she missed the day after. I have also had several eggs weighing 4¼ and 4¾ ozs. I have had very little disease in my yard during the past year, and this I attribute to careful feeding, cleanliness, and the use of the solution of sulphate of iron in

water; for rearing chickens and keeping adult fowls in good condition, it is excellent. For fowls which are drooping and have black combs, and all the other signs of impaired digestion, the receipt which you were kind enough to give me is very good—viz., a teaspoonful of whiskey, and a few meals of soft food afterwards.

My stock consists of two Cochin hens, twelve Silver-pencilled Hamburghs and cock. I have only put down the mere necessary expenses, such as food, &c., and not those attendant upon exhibiting, and, on the other hand, I have reckoned the sale of eggs and chickens at the common market price.

BRAHMA POOTRAS AT BRISTOL SHOW.

The rejoinder of "Y. B. A. Z." last week, to my complaint respecting his criticism on my pen of Brahmas, is of such a character that I cannot pass it by in silence.

I will take the personal matter first. Of his unnoticed single cock he says that I admired him exceedingly a few weeks before the Show, and would gladly have purchased him, also preferring his cocks generally to those of Mr. Boyle. This he implies is grossly inconsistent with my remark, that by his peculiar hobby he has to a great extent ruined his yard. He, of course, thought it still more so, that I should (as I innocently did the day after my complaint appeared), apply to him for a hen, I need scarcely now add without success. No experienced breeder, however, who knows how to use the "points" in any particular yard, would think the remark and the fact at all incongruous; and even casual readers would have seen no inconsistency had he added, as in strict fairness he should have done, that my expressed desire for this bird and preference of some of his cocks to Mr. Boyle's, were grounded specially and solely upon the clearness and sharp marking of the wing, for which I consider his strain to be remarkable, and which I wished to import into the other. I have still a note from him referring to "the experiment" I wished to try, which is a very different thing to selecting the bird for exhibition. He ought, also, to have added, that I did at the time, if my memory serves me, refer to the small amount of vulture hock in the cock in question as a decided fault in an otherwise good bird. I may add for myself, what is well known to "Y. B. A. Z.," that although I have no wish to see vulture hocks expressly authorised, I so far agree with him that I should like to see a small amount of it *tolerated*, for the sake of the heavy leg-feathering it tends to produce. The conversation he refers to took place early in November, some weeks before either of the two great shows of last year, and when, "from information I received," I had some reason to hope such might be the case; but the result of the judging at both the Shows referred to quite convinced me the question was *settled* for two or three years at least, and birds I would formerly have bred from, I should on that account now reject. I will only observe further on this point, that in alluding to this particular cock my object was very obviously not to decry him as a bad bird, but simply to point out, that whilst criticising a near neighbour's winning pen, his own exhibition "standard of excellence" did not seem to find favour with the Judges.

So, also, in speaking of "ruin" in his yard, I, of course, meant simply, that to persistently and avowedly *cultivate* what Judges reject must render a large portion of stock useless for exhibition, and unadvisable for breeding-purposes. I do not see how this can be denied; but it does not follow there are not still plenty of birds free from the defect, and the amount of "ruin" wrought in any strain crossed from such a yard will obviously depend entirely upon the amount of judgment shown in the selection. "Two or three years back," when the satisfactory cross he refers to took place, the vulture-hock controversy had not reached its present point. With these explanatory remarks, I have no reason whatever to doubt his assertion that the gentleman referred to, whom he afterwards mentions by name, and who is confessedly the most eminent exhibitor of Dark Brahmas in the three kingdoms, owes his success to him. To what extent his yard was crossed from that of "Y. B. A. Z." I have no means of knowing; but all Brahma breeders will feel grateful to have pointed out to them the sure highway to such marked success, and it heightens my regret that my own application for just one single hen should have met with a curt refusal.

"This is sorter ironnicle," as Artemus Ward says; but I will add seriously, that I much regret having been led into any remarks on a neighbour's fowls. It may be and is quite true, that "Y. B. A. Z." brought it upon himself fairly by a wholesale depreciation of my own birds, which I felt the more as coming from one so near, whose judgment would weigh with neighbouring fanciers, as I have already cause to believe has been the case. Still I regret having followed his example, and need scarcely say that my reason for doing so was not to retaliate, but only to show that the standard to which he breeds his own birds was little likely to make him a fair judge of mine.

I shall add little more, as "defence, not defiance," is my only object. A casual *mention* of Messrs. Hewitt and Douglas as "eminent judges," can hardly be called "praising" them, which I had no thought of doing; but since he has mentioned them again, I will just remark, that Mr. Douglas is himself a successful breeder of Brahmas and knows their points well, whilst he is reputed to look rather sharply after good feathering; and of Mr. Hewitt there is a general opinion amongst those who have most studied his decisions, that he has, if anything, rather a special weakness for good combs.

In conclusion, had "Y. B. A. Z." made it clear that he simply called my birds "poorly feathered" from his own vulture-hocked point of view, or even as compared with Mr. Boyle's single cock mentioned by him, I should never have complained. The latter cock was certainly much heavier-feathered, and I think for his age was altogether the very best bird I ever saw; and if all that do not come up to his standard of feathering are to be called "poorly feathered," it will go hard with Mr. Boyle himself. "Y. B. A. Z." made the sweeping and absolute assertion that my pen was "coarse in the combs and poorly feathered," and the standard of comparison he furnished was the second-prize pen, which he said "was better," and, therefore, he *did* certainly "virtually question" the decision of the Judges. I have never yet said my pen was *heavily* feathered, nor am I going to discuss the merits of the really splendid second-prize pen; but I say as a matter of simple fact, that be their *general* merits greater or less, their leg-feathering was not one whit heavier than my own, and that both were good. I agree with "Y. B. A. Z.," that the class as a whole was very inferior; but I consider being placed before even one pen of such real merit no mean triumph, which I cannot submit to have criticised away, even by such fearful-looking initials as those adopted by my Persian Mentor.
—L. Wright, *Southwell Street, Kingsdown, Bristol.*

[Here this controversy must cease. We are quite sure that neither of our correspondents intended either to depreciate the other's fowls, or to annoy their owner.—Eds.]

JEDBURGH EXHIBITION OF POULTRY AND PIGEONS.

The Show held at Jedburgh on the 30th and 31st of January was the ninth annual meeting that has taken place under the management of the Jedburgh Committee, a body of gentlemen who are evidently quite alive to the necessities of a show, and who, knowing how matters should be carried out, use every possible exertion to do all things properly. This season they had quite a complication of drawbacks to encounter. First, the date of their meeting was encroached upon by half a dozen other shows; and, again, a far greater difficulty arose from the almost unparallelled severity of weather that for many weeks had snow-bound the whole district. Their Show, however, proceeded, and the result was a far better meeting than the most sanguine of the Committee anticipated. The Corn Exchange, in which the Exhibition was held, was most artistically decorated with evergreens and a variety of artificial flowers. Taking into consideration the late severe weather the number of empty pens was very small. We could not help observing, however, that many otherwise most praiseworthy pens were suffering severely from frost-bite. This, strange to say, was especially evident in the Dorking classes, even far more than in the Spanish fowls, usually considered so much more tender.

The *Spanish* were exceedingly good, as were also the *Dorkings*, but spurs outside the legs were of frequent occurrence. In selecting the breeding stock for the coming season it would be well for all owners to

eschew altogether such birds as possess this malformation, as it is almost invariably transmitted to the progeny. In *Cochins* the Buffs were as a whole the best of any. The *Brahmas* did not show to advantage. There were many very excellent *Game* fowls shown; among them was one that for several years past "always took the first prize." His ever doing so again is now quite impossible, for when fighting at a show with his next neighbour, unfortunately he broke away completely the upper mandible of his bill, so that his only utility for the future will be as a stock bird. It is a great pity that such an accident should have happened to so good a bird, but neither lapso of time nor any application whatever can restore the injured bill sufficiently for exhibition. In *Hamburghs* the Show was very good, although it might be almost called Mr. Beldon's Show of Hamburghs, for this gentleman secured, in spite of a really good competition, first and second prizes in all four varieties. Some marvellously good *Polands* were also shown from the same yard, both Silver-spangled and Black. There was likewise a very fair collection of *Game Bantams*, but the late frosts had evidently caused much deterioration in not a few of these tiny birds.

The Ayleshury were decidedly better than the Rouen *Ducks*, and the Extra variety class for Ducks was peculiarly good. It embraced Mandarins, Carolinas, Shell Ducks, Wigeons, Pintails, and many other breeds. From Mr. Jennison's fine birds being detained on the railway, as the Committee were informed by a telegram, this class was reserved unjudged until past five o'clock in the afternoon, yet they did not arrive in time to receive the honours they so well deserved, as it was imperative to get out the catalogue for the opening time in the morning. The *Turkeys* and *Geese* were quite equal to those exhibited even at our largest shows, and the competition was generally severe. This was a singular feature when it is remembered that the carriage of these weighty birds to so remote a district would cause a considerable outlay to exhibitors. The Selling classes, as usual now-a-days, were well filled, and great numbers of pens changed hands. It is worthy of remark that selling classes were first introduced to public favour by the Jedburgh Committee a few years ago. The *Pigeons* and *Canaries* proved a very interesting collection, and almost invariably these birds were shown in excellent feather. With the general attention displayed by the Committee, no doubt the Jedburgh Exhibition will annually increase both in entries and importance.

SPANISH.—First, H. Beldon, Goit-stock, Bingley, Yorkshire. Second, A. Redpath, Edinburgh. Third, B. Murdie, Jedburgh. *Chickens.*—First, H. Beldon. Second, A. Redpath. Third, J. Anderson, Friarshall, Melrose. Commended, R. Ballantine, Hawick; D. Geilatly, Meigle, Perthshire.

DORKINGS (Coloured).—First and Third, Lord Binning, Mellerstain. Second, H. Beldon.

DORKINGS (Silver).—First, J. Smith, Breeder Hill's, Grantham. Second, Lady Baird, Newbyth, Haddington. Third, J. Hardie, Corbie. Commended, W. Cheyne, Selkirk.

DORKINGS (Coloured or Silver).—*Chickens.*—First, J. Carror, Comieston, Lothianburn. Second, Lord Binning. Third, J. Hardie. Highly Commended, T. Raines, Stirling. Commended, Countess de Flahault, Tullyallan Castle; T. L. Jackson, Bush Ewes. *Pullets.*—First and Third, Countess de Flahault. Second, J. Hardie. Commended, Lord Binning; T. Raines.

COCHIN-CHINA (Any variety).—First, Miss Nelson, Eaglesfield, Dumfries. Second, E. A. Aglionby, Esthwaite Lodge, Hawkshead (Partridge). Third, J. Stuart, Thistle Bank, Helensburgh (Buff). Highly Commended, Mrs. Ford, Hardengreen, Dalkeith (White); W. R. Park, Abbotsmeadow, Melrose (Buff). *Chickens.*—First, E. A. Aglionby (Buff). Second, W. R. Park White). Third, Mrs. Ford (White). Highly Commended, H. Beldon; J. Stuart (Buff); J. Barton, Jedburgh (Buff). Commended, C. Pease, Darlington (Buff).

BRAHMA POOTRA.—First, C. Pease. Second, J. Muirhead, Salton Mains. Third, J. Waugh, Castlehill, Lochmaben. *Chickens.*—First, Capt. Fisher, Albyn Place, Aberdeen. Second, E. A. Aglionby. Third, Mrs. Craw, Jedburgh.

GAME (Black or Brown Red).—First, J. Brough, Carlisle. Second, Lord Binning (Black-breasted). Third, J. Hardie (Black Red).

GAME (Any other variety).—First Withheld. Second, W. Easton, Jedburgh (Duckwings). Third, F. L. Roy, jun., Nenthorn (Duckwings). *Chickens.*—First, J. Smith (Brown Red). Second, J. Brough, Carlisle (Black Red). Third, W. Riddell, Selkirk (Brown Red.)

HAMBURGHS (Silver-spangled).—First, H. Beldon. Second, W. France, Crieff. Third, J. Bowe, Carlisle. Highly Commended, H. Beldon. Commended, F. L. Roy, jun.; Mrs. Craw, Jedburgh.

HAMBURGHS (Silver-pencilled).—First and Second, H. Beldon. Third, T. J. Harrison, Singleton Park, Westmoreland. Commended, G. Walker, Selkirk.

HAMBURGHS (Golden-spangled).—First, H. Beldon. Second, R. Dickson, Selkirk. Third, J. Turnbull, Selkirk. Commended, T. Musgrove, Longtown.

HAMBURGHS (Golden-pencilled).—First and Second, H. Beldon. Third, R. Burrow, Longtown. Commended, D. Normand, Kennoway, Fife; W. R. Park.

BANTAMS (Any variety).—First, W. Mabon, jun., Jedburgh (Black Red). Second, G. Young, Sprouston (Duckwing Game). Third, W. Dixon, Sunderland (Black Red). Extra Third, D. Broomfield, Kelso (Game). Highly Commended, R. Youll, Sunderland (Black Red); J. Sword, Jedburgh (Duckwing); J. Kerr, Sprouston (Duckwing Game); W. Easton, Jedburgh (Brown Red). Commended, G. Turnbull, Kirriemuir (Black Red); W. Hodgson, Darlington (Game); F. L. Roy, jun. (Black Red); E. A. Aglionby (Pile Game),

BANTAMS (Any other variety).—First, J. R. Jessop, Beverley Road, Hull. Second, F. L. Royd, jun. (Silver Sebright). Third, J. Barton, Jedburgh (Black). Commended, F. L. Roy, jun. (Black).

ANY OTHER VARIETY.—First, Countess de Flahault (La Flèche). Second, W. R. Park (Crève Cœur). Third, H. Beldon (Polands). Highly Commended, H. Beldon (Polands); Countess de Flahault (La Flèche); J. A. S. E. Fair (White Dorkings). Commended, W. E. Otto, Jerdonfield.

GEESE (Any variety).—First, Miss Swan, Bush (Toulouse). Second, T. E. Boog, Lanton (Toulouse). Third, Mrs. Sanderson, Magdalenhall (Chinese).

DUCKS (White Aylesbury).—First and Second, J. A. S. E. Fair, Gillicstonques. Third, E. Leech, Rochdale. Highly Commended, — Finlay, Jedburgh; Messrs. Swan & Hood, Bush. Commended, J. Steel, Kelso.

DUCKS (Rouen).—First, J. H. Frame, Overton. Second, J. Hardie. Third, J. Gray, Sharplaw. Highly Commended, J. Hall, Broombaulks. Commended, Mrs. Craw.

DUCKS (Any other distinct breed).—First, T. C. Harrison (Mandarins). Second, J. R. Jessop. Third, H. Beldon (Call Ducks). Commended, J. Slater, Eccles (Wild Ducks).

TURKEYS.—*Poults.*—First, J. Smith. Second, Lord Binning. Third, E. Leech, Rochdale. Highly Commended, T. L. Jackson.

SWEEPSTAKES FOR BANTAMS.—First, G. Turnbull, Kirriemuir (Black Red Game). Second, W. Brown, Selkirk (Black Red Game). Third, J. Renilson, Selkirk (Black Red Game). Highly Commended, J. Park, Jedburgh (Black Red). Commended, G. Young, Sprouston (Duckwing Game); J. Scott, Selkirk (Black Red Game); J. Lunn, Glenburnhall (Duckwing); F. L. Roy, jun. (Black Red).

SELLING CLASS.—First, T. L. Jackson (Turkeys). Second, W. Paterson, Langholm (Spanish). Third, G. Macmillan (Manorkies). Highly Commended, T. L. Jackson (Dorkings); Mrs. Birkett, Penrith (Dorkings); J. Hardie (Dorkings); Mrs. Craw (Cochin China, Brahma Pootra); J. A. S. E. Fair (Aylesbury Ducks). Commended, R. Scott (Aylesbury Ducks); Messrs. Swan & Hood, Bush (Aylesbury Ducks); Miss Swan, Bush (Turkeys).

COTTAGERS' PRIZES.—First, A. Stevenson, Cessford (Game). Second, R. Sword. Third, G. Macmillan (Silver-spangled Hamburghs). Highly Commended, A. Stevenson (Game). Commended, W. Sinton, Selkirk (Brahma Pootra); W. E. Miller, Selkirk (Silver Dorkings).

SINGLE COCKS.

DORKINGS.—First, J. H. Frame, Overton. Second, J. Hardie. Third, Countess de Flahault.

GAME.—First, J. Hardie. Second, H. M. Julian, Hull. Third, J. Brough.

HAMBURGHS.—First, H. Beldon. Second, J. U. Somner, Jedburgh. Third, T. E. Boog. Highly Commended, H. Beldon. Commended, F. L. Roy.

PIGEONS.

TUMBLERS (Almond).—First, J. Bell, Newcastle. Second, P. A. Renwick, Kelso. Third, R. Thomson, Moresdalehall, Kendal.

TUMBLERS (Any other variety).—First, F. D. Wood, Edinburgh. Second, J. Fielding, Rochdale. Third, H. Yardley, Birmingham. Highly Commended, J. E Spence, Millhill, Musselburgh (Short-faced); J Campbell, Distillery, Langholm (Short-faced); J. Bell, Newcastle (Kites).

FANTAILS.—First, J. Grant, Corstorphine. Second, J. Bell, Newcastle. Third, Highly Commended, and Commended, W. R Park.

POUTERS.—First and Third, J. Grant. Second, F. Keir.

NUNS.—First, R. Paterson. Second, W. Scoon, Melrose. Third, R. Davidson, Jedburgh. Highly Commended, H. Yardley.

OWLS.—First and Second, J. Fielding. Third, F. D. Wood, Edinburgh. Highly Commended, T Spence, Millhill; W. R. Park.

TURBITS.—First, R. Paterson. Second, H. Yardley. Third, R. Thomson. Highly Commended, F. D. Wood; R. Thomson. Commended, R. Davidson.

JACOBINS.—First, P. A. Renwick. Second, F. D. Wood. Third, Countess de Flahault. Highly Commended, R. Thomson; F. D. Sanderson.

ANY VARIETY.—First, J. Campbell (Magpies). Second, H. Yardley. Third, Mrs. Craw (Dragons). Highly Commended, Countess de Flahault (Runts); Mrs. Craw (Victoria); G. Bell. Commended, F. D. Wood, Edinburgh (Swallows, Trumpeters); A. Goodfellow.

SELLING CLASS.—First, A. Anderson, Edgerston (Barbs). Second, J. Grant, Corstorphine. Third, R. Davidson (White Dragons). Highly Commended, J. R. Jessop (Owls); H. Yardley; J. Barton, Jedburgh (Baldhead). Commended, A. Ormiston (Jacobins).

CANARIES.

SCOTCH FANCY (Yellow).—*Cock.*—First, J. Blackie, Jedburgh. Second, J Dalgleish, Galashiels. Highly Commended, J. Bell, Jedburgh. Commended, R. Ballantyne, Hawick. *Hen.*—First, J Kemp, Galashiels. Second, W. Tinline. Highly Commended, A. Ferguson. Commended, T. Scott.

SCOTCH FANCY (Buff).—*Cock.*—First, J. Kemp. Second, G. Laidlaw. Highly Commended, R. Ballantyne. Commended, G. Bennet. *Hen.*—First, A. Ferguson. Second, J. Hope. Highly Commended, T. Scott. Commended, R. Swanston, Jedburgh.

BELGIAN FANCY (Yellow).—*Cock.*—First, J. Barton. Second, J. Marshall, Galashiels. Highly Commended, J. Cleghorn. Commended, J. Hope. *Hen.*—First, J. Kemp. Second, W. Tinline. Highly Commended, J. Barton. Commended, J. Kemp.

BELGIAN FANCY (Buff).—*Cock.*—First, J. Kemp. Second, G. Laidlaw. Highly Commended, G. Laidlaw. Commended, J. Dryden, Kelso. *Hen.*—First, W. Tinline. Second, J. Cleghorn. Highly Commended, J. Dryden. Commended, J. Kemp.

FLECKED CANARIES (Yellow).—*Cock.*—First, G. Walker, Kelso. Second, J. Cleghorn. Highly Commended, Mrs. Craw. Commended, G. Mabon. *Hen.*—First, G. Park. Second, G. Walker. Highly Commended, J. Hardie. Commended, G. Mahon.

FLECKED CANARIES (Buff).—*Cock.*—First, W. Laidlaw. Second, G. Walker. Highly Commended, G. Macmillan. Commended, W. Finlay. *Hen.*—First, W. Tinline. Second, W. Finlay. Highly Commended, J. Hall, Jedburgh. Commended, G. Park.

JUDGES.—*Poultry:* E. Hewitt, Esq., Sparkbrook, Birmingham; *Pigeons:* J. H. Frame, Esq., Overton, Carluke; *Canaries:* Mr Dewar, Edinburgh.

HALIFAX WINTER POULTRY SHOW.

THE second Show of this Society was held on the 2nd inst. in the Temperance Hall, Northgate. This building is ill adapted to the purpose of a show of such dimensions, for some parts are so badly lighted that it would be next to impossible to know a Black from a Golden-spangled bird at first sight; and in addition to this evil the space is so limited that the pens had to be put in double tiers, and so close to each other were the rows, that two persons were inconvenienced

to pass between them at one time. Arrangements would doubtless have been made for a more suitable building if the great increase of entries had been at all anticipated; for last year 114 included Canaries, while this year's schedule, for poultry and Rabbits alone, brought nearly 170 pens. The great difficulty of judging a show with such disadvantages will be easily perceived, and many expressed themselves surprised that any one would accept such a task. The Committee, whose care of the birds entrusted to their hands was most exemplary, will doubtless endeavour to secure more extensive accommodation for their future shows, seeing the very handsome manner in which they have been supported by exhibitors. The Show was well attended, especially in the latter part of the day, which would doubtless act beneficially on the spirits of the overworked Secretary.

Red *Game* were first in the list, and a magnificent pen of Brown Red chickens in this class won the cup for the best pen of Game in the Show. The second prize was awarded to a pen containing a very handsome Black Red cock, but the hen mated with him showed more pencilling on the wing than was desirable. In the Variety class for Game Mr. Firth's well-known Duckwing chickens were first, the second prize going to a capital pen of old birds from Beverley. The *Spanish* classes were good. The splendid old birds of Messrs. Burch & Boulter were first; the second and third prizes went to two pens of handsome chickens. The *Cochin* class was not good, crooked tails and twisted combs being the rule. Of *Brahma Pootras* there were several very good pens; Col. Stuart Wortley's pen of young birds beating Mr. Pickles's celebrated old pen, which looked sickly and out of condition. Spangled *Hamburghs* were very good, but, except the first-prize pen, the pencilled Hamburghs were bad. *Game Bantams* were a very large class, the first and second prizes being awarded to two beautiful pens of Duckwings, the third to a smart little pen of Black Reds. Bantams, any other variety, had some nice pens, the first-prize pen of Whites being of great beauty and striking appearance, Laced and Black following second and third. A capital pen of Silver *Polands* was awarded first for any other variety not previously named, and carried off the cup for the best pen of poultry in the Show, Game excepted; very closely pressed, however, by Mr. Preston's pen of Silver Polands, the comparative rarity of the former only deciding in their favour.

The class for Lop-eared Rabbits was large, having twenty-five entries. The medal for the best pen was given to Mr. Newsome's Blue buck, which out-distanced all competition. The next in excellence was a capital Black doe from Sheffield. One of the best Rabbits in this class was disqualified, owing to a large blemish over its left eye. Himalayas were as pretty as ever, and well worthy the attention bestowed on them; and the prize-winners in Angoras were like balls of swan's down.

A capital Black Red Game chicken was shown in the Extra stock class by the Secretary, though not for competition.

GAME (Black-breasted).—Cup, E. Akroyd, Bradford. Second, T. Bottomley, Shelf, near Halifax. Third, R. Pashley, Worksop. Highly Commended, J. Gelderd, Colliu Croft; R. Pashley; J. Crossland, jun. Commended, A. Fenton, Crimble Hall, Rochdale; J. Hodgson, Bradford.

GAME (Any other variety).—First, J. Firth, Halifax. Second, W. Boves, Beverley. Third, A. Fenton. Highly Commended, A. Hodgson, Illingworth, near Halifax; T. Sunderland, Halifax.

SPANISH (Black).—First, Messrs. Burch & Boulter, Sheffield. Second, J. Preston, Allerton, near Bradford. Third, J. Marchant, Halifax Highly Commended, J. Thresh, Bradford; W. McMellon, Glossop. Commended, J. Newton, Silsden, near Leeds; W. Roberts, jun., Halifax.

COCHIN-CHINA.—First, J Oates, Stoney Royde, Halifax. Second, H. Crossley, Broomfield, Halifax. Third, C. E Ridsdale, Copely, near Halifax. Highly Commended, J. Wade, Copely Mills, near Halifax; T. Rogers, St. Helens, Lancashire. Commended, C. E. Ridsdale.

BRAHMA POOTRA.—First, Col. Stuart Wortley, Grove End Road, London. Second, J. H. Pickles. Third, J. Smithson, Lightcliffe, near Halifax. Highly Commended, Rev. W. J. Mellor, Colwick Rectory, Nottingham; J. H. Pickles; J. Smithson. Commended, M. Brookshank, Manchester.

HAMBURGHS (Gold or Silver-spangled).—First, J. Ogden, Hollingwood, near Manchester. Second, J. Preston. Third, H. Firth, Dudley Hill, near Bradford. Highly Commended, Messrs. S. & R. Ashton, Mottram, near Manchester; H. Jennings, Allerton near Bradford. Commended, W. Bairstow, Fearnecliffe.

HAMBURGHS (Gold or Silver-pencilled).—First, J. Preston. Second, H. Pickles, jun., Earby, near Skipton. Third, F. Pittis, jun., Newport, I.W. Highly Commended, H. Greenwood, Woodhall Hills, near Leeds; T. Briggs, Fearnecliffe, Bingley.

GAME BANTAMS.—First, J. Crossland, jun Second, F. Pittis, jun. Third, G. Noble, Staincliffe, Batley. Highly Commended, Rev. W. J. Mellor; F. L. Roy, Nenthorn, Kelso; A. Fenton; J. Crossland, jun.

BANTAMS (Any other variety).—First, J. R. Jessop, Hull. Second, Messrs. S. & R Ashton (Laced). Third, H. Draycott, Humberstone, Leicester (Black). Highly Commended, J. Walker, Halifax (Laced); F. L. Roy (Laced).

ANY OTHER VARIETY NOT PREVIOUSLY MENTIONED.—Cup and First, J. Colston, Sowerby Bridge (Silver-spangled Polands). Second, Col. Stuart Wortley (French Fowls). Third, S. T. Beaumont, Hudderafield (Dorkings). Highly Commended, S. T. Beaumont (Polands). Commended, Messrs. Walton & Widdop, Booth Town (Dorkings); Col. Stuart Wortley (Silkies); M. Brookshank, Manchester (Dorkings).

EXTRA STOCK.—Very Highly Commended, T. Dyson, Halifax (Game). Highly Commended, C. E. Ridsdale, Copley (Cochin-China); W. Walker (Black Spanish). Commended, W. H. Green (Game Bantams).

RABBITS.

SPANISH.—Medal, W. Newsome, Leeds (Lop-eared). Second, W. Allison, Sheffield (Black Doe). Highly Commended, S. A. Willie, East Moulsey, Surrey (Sooty Fawn Buck); J. Warden, Halifax (Smut Buck); W. Newsome (Lop-eared); W. Allison (Grey Buck); C Gravil, jun., Thorne, near Doncaster (Doe and Buck). Commended, J. Warden (Grey Doe and Buck).

HIMALAYAN.—First, H. Cawood, Thorne, near Doncaster. Second, F. Horsfall, M.D, Carlton Grange, near Pontefract. Highly Commended, J. R. Jessop, Beverley Road, Hull; J. Alderson, Claremount, Halifax; C. Rayson, York Mount, Prestwich. Commended, T. Hawkes, York; J. Shaw, Mount Pleasant, Halifax.

ANGORA.—First, J. Alderson. Second, A. Parry, Rochdale. Highly Commended, C. Rayson. Commended, M. Huntsworth, Halifax; J. Shaw.

JUDGE.—Mr. E. Hutton, Pudsey, Leeds.

NEWCASTLE-UPON-TYNE ORNITHOLOGICAL ASSOCIATION.

THIS Society held their first annual Exhibition of Canaries and Pigeons in a room of the Half Moon Inn, Bigg Market, on the 25th and 26th ult.

The Pigeon pens were constructed of deals with wire fronts; 112 pens were shown, including the selling class. We fear the Society will be losers, as too little notice was given of the Exhibition; besides, the room was not a suitable place for the purpose.

There was a good show of *Canaries*, which were ranged down the centre of the room, and the *Pigeons* round the walls.

Carriers mustered four pens, and were poor, except the first prize pair, which were a first-class hen and a fair cock. Pouters, with the exception of the winning pens, were also poor. Almond Tumblers were a good class. Mr. F. Key received high commendations for a capitally matched pen, which certainly ought to have been second. Short-faced Tumblers, of any other colour, were also good; but the first and second prizes should have been reversed. In Trumpeters, the first prize went to an excellent pair of Blacks, the second to equally good Mottles; but one of the latter birds was out of health, and unfit for exhibition. Nuns were not remarkable. The first and second Barbs were first-class, and would hold good positions at some of the best shows. The Fantail class was good, but the second-prize pair was not entitled to that position, there being four better pens exhibited. In Magpies, the second prize was given to a coarse pair of Blacks, a fine pair of the same colour receiving high commendation. The first prize went to a nice pair of Swallows. The first prize in Jacobins went to a moderate pair of Reds, one of the birds having a blemished eye. The best pair arrived too late for competition, but the class contained better competitors than the recipients of the prize. Both prizes were taken by Yellows in the class for Turbits, but the second-prize birds were coarse and large. Some fair Reds and Blues were shown. In the class for English Owls, some good birds competed, but the best pen was unnoticed. In the Variety class a pair of good Blue Swallows was first, Archangels second. The following is the list of prizes:—

CANARIES.

BELGIAN (Clear Yellow).—First, W. Gillson, Sumae Street. Second, H. Hall, Gateshead.

BELGIAN (Clear Buff).—First, J. Baxter, Newcastle. Second, W. Davidson, Newcastle. Very Highly Commended, J. Wilson, Scotswood Road, Newcastle.

BELGIAN (Variegated Yellow or Buff).—First, W. Gillson. Second, J. Wilson.

GLASGOW DON (Clear Yellow).—First, H. McDougdale, Edinburgh. Second, R. Forsyth, Edinburgh. Highly Commended, J. Forsyth, Elswick East Terrace.

GLASGOW DON (Clear Buff).—First, J. A. Currie. Second, J. Forsyth. Highly Commended, R. Forsyth.

GOLDFINCH MULE (Yellow).—First, R. Wardle, Gilesgate Moor. Second, J. Wynn, Northampton.

GOLDFINCH MULE (Buff).—First, R. Wardle. Second, G. Parkinson, Houghton-le-Spring. Very Highly Commended, R. Hawman, Middlesborough. Highly Commended, J. Wynn.

GOLDFINCH MULE (Dark).—Prize, T. Robinson.

LINNET MULE.—First, J. Baxter. Second, W. Blair, Earrington Colliery, Bedlington.

NORWICH (Clear Yellow).—First, J. Smart, Newcastle. Second and Very Highly Commended, G. Parkinson.

NORWICH (Clear Buff).—First, H. Yeld, East Sunderland. Second, J. Wynn. Very Highly Commended, G. Symington, Newcastle. Highly Commend, T. Johnson.

NORWICH (Variegated, or four Marked Yellow).—First, J. Spence, Bishopwearmouth, Sunderland. Second, R. Hele. Very Highly Commended, J. Baxter.

NORWICH (Variegated, or four Marked Buff).—First, J. Baxter. Second, J. Spence. Very Highly Commended, G. Parkinson.

LIZARD (Golden-spangled).—First, T. Robinson, Middlesborough. Second, W. Gillson.

LIZARD (Silver-spangled).—First and Second, T. Robinson.

DUN (Yellow Cinnamon).—First and Second, G. Moore, Northampton. Highly Commended, H. Yeld.

DUN (Buff Cinnamon).—First and Second, G. Moore.

DUN (Yellow marked).—First and Second, G. Wilkinson.

DUN (Buff-marked).—First, E. Baker. Second, G. Wilkinson.

CLEAR GREEN.—First, E. Baker. Second, M. Brown, High Felling, Gateshead. Very Highly Commended, H. Yeld; G. Atkinson, Gateshead; W. Davidson.

COMMON FOUR MARKED.—First, J. Baxter. Second, G. Wilkson. Very Highly Commended, R. Kipling, Forth Terrace; J. Baxter. Highly Commended, J. Carr.

GOLDFINCH.—First, R. Wardle. Second, G. Wilkinson. Very Highly Commended, G. Atkinson.

GROUP OF TEN CANARY BIRDS, OR UPWARDS, IN ONE CAGE, IRRESPECTIVE OF COLOUR.—First, J. Blakey, Bath Lane. Second, R. Daniels.

PIGEONS.

CARRIERS.—First, N. Stephenson. Second, T. Thompson, Wideopen. Highly Commended, T. C. Taylor, Middlesborough.

POUTERS.—First, C. Vaux, Sunderland. Second, J. E. Spence. Highly Commended, T. Thompson.

TUMBLERS (Short-faced Almond).—First, R. Daniels. Second, G. Fawdon, Pipewellgate. Highly Commended, F. Key, Beverley, Yorkshire; N. Stephenson.

TUMBLERS (Short-faced, any colour).—First, T. Rule. Second, G. Fawdon. Highly Commended, N. Stephenson.

TRUMPETERS.—First, R. Gray. Rabbit Banks. Second, C. Vaux. Very Highly Commended, R. Daniels.

NUNS.—First, C. Bulfin, Bridgewater, Somerset. Second, T. C. Taylor.

BARBS.—First, G. Fawdon. Second, C. Vaux. Highly Commended, R. Daniels.

FANTAILS.—First, G. Fawdon. Second, N. R. Parker, Melrose. Highly Commended, N. Stephenson.

MAGPIES.—First, C. Bulpin. Second, C. M. Byers, Seaton Sluice. Highly Commended, G. Fawdon.

JACOBINS.—First, C. Vaux. Second, P. A. Renwick. Highly Commended, J. G. Spence.

TUMBLERS.—First, P. Stephenson. Second, R. Daniels. Highly Commended, W. Youl; T. Rule.

TURBITS.—First, G. Fawdon. Second, J. Thompson. Highly Commended, W. B. Van Haanshergen.

ENGLISH OWLS.—First, R. Daniels. Second, P. Stevenson. Highly Commended, N. R. Parker.

ANY OTHER DISTINCT BREED.—First, G. M. Byers (Swallows). Second, R. Gray (Archangels). Highly Commended, T. C. Taylor.

JUDGES.—Mr. Robert L. Wallace; Mr. John Crawford, and Mr. Thomas Lowery.

SOUTH OF IRELAND POULTRY, PIGEON, AND CAGE BIRD ASSOCIATION.

THE sixth annual Exhibition of Poultry, Pigeons, and Song Birds, was held in the Athenæum, Cork, on the 30th and 31st of January.

The following prizes were awarded:—

SPANISH.—First, J. C. Cooper, Cooper's Hill, Limerick. Second, H. L. Tivy. Highly Commended, Mrs. Dring, Rockgrove; Mrs. Hay. *Chickens.* First, R. P. Williams, Clontarf. Second, J. C. Cooper. Highly Commended, Mrs. Dring; F. Y. Gilbert (White Spanish; A. E. Allen, Cork.

DORKINGS (Coloured).—First, R. P. Williams. Second, J. C. Perry, Browning's Town, Cork. *Chickens.*—First, Mrs. Dring. Second, Mrs. Webb. Highly Commended, R. P. Williams. Commended, Mrs. Dring; J. C. Cooper; T. O'Grady, Roughgrove, Bandon; F. W. Zurhorst, Belville, Donnybrook.

DORKINGS (Silver-Grey).—First, T. O'Grady. Second, Rev. J. O'Sullivan. *Chickens.*—First, T. O'Grady. Second, J. C. Cooper. Highly Commended, R. P. Williams; F. Hodder. Commended, Rev. J. O'Sullivan; T. O'Grady.

DORKINGS (White).—First, J. C. Perry. Second, Countess of Bandon.

COCHIN-CHINA (Buff or Lemon).—First, R. P. Williams. Second and Highly Commended, Mrs. Hay.

COCHIN-CHINA (Partridge or Grouse).—First, Mrs. Webb. Second, J. C. Cooper.

COCHIN-CHINA (White).—First, F. W. Zurhorst. Second, Miss L. Pike.

BRAHMA POOTRAS.—First and Second, R. W. Boyle, Bray, Co. Wicklow. Highly Commended, J. C. Cooper; Miss J. B. Haughton.

CRÈVE CŒURS.—First and Highly Commended, J. C. Cooper. Second, J. C. Perry.

GAME (Black or Brown Reds).—First, C. F. Staunton, Clondalkin (Brown). Second, J. Lloyd (Black). *Chickens.*—First and Second, J. C. Cooper.

GAME (Duckwings, Piles, or others).—First and Commended, J. C. Perry. Second, A. E. Allen, Cork. *Chickens.*—First and Second, A. E. Allen (Piles and Greys).

POLANDS (White Crests).—First, R. P. Williams. Second, J. C. Perry.

POLANDS Spangled).—First, J. C. Cooper. Second and Commended, R. P. Williams (Silver and Gold).

HAMBURGHS (Pencilled).—First, F. W. Zurhorst (Gold). Second, Mrs. Dring (Gold). Commended, J. C. Perry (Gold).

HAMBURGHS (Spangled).—First, J. C. Cooper. Second, T. O'Grady. Highly Commended, J. C. Perry. Commended, R. P. Williams; Mrs. Dring.

BANTAMS (Sebright).—First, Hon. Mrs. H. B. Bernard. Second, R. P. Williams.

GAME BANTAMS.—First, T. O'Grady. Second and Highly Commended, W. D. Allen. Commended, J. Lloyd.

BANTAMS (Silky).—First and Second, J. A. Fitzpatrick. Commended, C. F. Staunton.

ANY OTHER VARIETY.—First, J. C. Cooper (Malay). Second, F. U. Zurhorst (Sultans). Extra Second, F. U. Zurhorst (French); J. C. Cooper (La Flèche). Highly Commended, F. Y. Gilbert (Houdan; Hon. Mrs. H. B. Bernard (Sultans). Commended, F. W. Pim (Houdan); J. C. Perry (Houdan); F. Y. Gilbert (Houdan); J. C. Cooper (Houdan and Malay).

TURKEYS.—First, J. C. Cooper. Second, Rev. J. O'Sullivan. *Poults.*—First and Second, J. C. Cooper.

GEESE (Coloured).—First and Second, J. C. Cooper.

GEESE (White).—First and Second, J. C. Cooper. Commended, J. C. Perry.

DUCKS (Aylesbury).—First, J. C. Cooper. Second, R. P. Williams. Commended, J. C. Perry. *Ducklings.*—First, Countess of Bandon. Second, R. P. Williams. Highly Commended, J. C. Cooper.

DUCKS (Rouen).—First, R. P. Williams. Second, Rev. J. O'Sullivan. Commended, J. C. Cooper. *Ducklings.*—First and Second, R. P. Williams.

DUCKS (Any other variety).—First and Commended, R. P. Williams (Shell Ducks and Buenos Ayrean). Second, Countess of Bandon (Carolina).

MRS. LYON'S MEDAL.—Medal, F. H. Zurhorst.

PIGEONS.

POUTERS (Yellow Pied).—First, A. W. Shaw, Limerick. Second, J. H. Perrott, Cork.

POUTERS (Black Pied).—First and Highly Commended, Dr. Harvey. Second and Commended, J. H. Perrott.

POUTERS (Blue or Silver Pied),—First, A. W. Shaw. Second, Dr. Harvey. Highly Commended, Dr. Harvey; J. H. Perrott. Commended, J. H. Perrott.

POUTERS (Red Pied, Mealy, or other Colour).—First, A. W. Shaw, Second, Dr. Harvey. Highly Commended, A. W. Shaw; D. Harvey. Commended, A. W. Shaw; Dr. Harvey; J. H. Perrott.

POUTERS (White).—First, Dr. Harvey. Second, J. H. Perrott. Highly Commended, A. W. Shaw. Commended, Dr. Harvey.

CARRIERS (Black).—First, Dr. Harvey. Second, A. W. Shaw. Highly Commended, Dr. Harvey. Commended, P. M'Carthy; Dr. Harvey.

CARRIERS (Dun).—First, Dr. Harvey. Second, A. W. Shaw.

CARRIERS (Blue or other colour).—First, R. Daly. Second, A. W. Shaw.

TUMBLERS (Short-faced Almonds).—First, Dr. Harvey. Second and Commended, A. W. Shaw.

TUMBLERS, KITES (Short-faced).—First and Second, A. W. Shaw.

TUMBLERS (Short-faced, Mottles, or others).—First and Second, A. W. Shaw (Mottles).

TUMBLERS (Short-faced, Balds, or Beards).—First, J. B. Blennerhassett. Second, R. A. Blennerhassett. Commended, A. W. Shaw.

TUMBLERS (Commons, Balds, or Beards).—First, J. B. Blennerhassett, Second, A. W. Shaw. Commended, J. B. Blennerhassett; A. W. Shaw.

TUMBLERS (Common, any other colour).—First, J. H. Perrott. Second A. W. Shaw.

BARBS (Black or Dun).—First, A. W. Shaw. Second, J. H. Perrott. Highly Commended, J. Lloyd. Commended, A. W. Shaw.

BARBS (Any other colour).—First and Second, J. H. Perrott (Yellow and Red). Highly Commended, A. W. Shaw (Yellow and White); G. Wherland. Commended, G. Wherland (Red and Yellow).

JACOBINS Red or Yellow).—First and Second, J. H. Perrott (Yellow). Highly Commended, A. W. Shaw (Red); J. Pike (Yellow). Commended, J. Lloyd Yellow); J. W. Edge (Yellow).

JACOBINS Any other colour).—First, A. W. Shaw (White). Second, J. H. Perrott (Mottled).

FANTAILS (White).—First, J. Pike. Second, A. W. Shaw. Highly Commended, T. O'Grady; J. H. Perrott; J. Pike.

FANTAILS (Any other colour).—First, J. W. Edge (Blue). Second, R. A. Blennerhassett. Highly Commended, J. W. Edge (Blue); J. Pike (Blue). Commended, J. Pike (Blue); J. Jefferies (Black)

OWLS (Blue or Silver).—First, J. Pike. Second, J. Jefferies. Highly Commended, J. H. Perrott. Commended, R. Russell.

OWLS (Any other colour).—First, A. W. Shaw (White). Second, J. W. Edge. Commended, J. Pike (Black).

TRUMPETERS (Mottled).—First and Second, J. H. Perrott. Commended, A. W. Shaw; J. H. Perrott.

TRUMPETERS (Any other colour).—First, A. W. Shaw (Black). Second, J. Pike. Highly Commended, J. F. Blennerhassett (Whites). Commended, T. O'Grady (White; A. W. Shaw (Whits).

TURBITS.—First, J. H. Perrott. Second, T. O'Grady. Highly Commended, J. B. Blennerhassett.

NUNS.—First, T. O'Grady. Second, C. F. Staunton.

MAGPIES.—First, T. O'Grady. Second, A. W. Shaw.

ANY OTHER VARIETY.—First, A. W. Shaw (German Toys). Second, J. Lloyd (Isabels). Highly Commended, J. Lloyd (Runts); Dr. Harvey (Pigmy Pouters Brunneas). Commended, A. W. Shaw (Frillbacks); Dr. Harvey (Isabels); J. H. Perrott.

SPECIAL PRIZE.—Society's Silver Medal, awarded to the exhibitor who wins the greatest number of points, A. W. Shaw.

SWEEPSTAKES FOR YOUNG PIGEONS.

POUTER (Any colour),—Prize, J. H. Perrott.

CARRIER (Black).—Prize, Dr. Harvey.

CARRIER (Dun).—Prize, Dr. Harvey.

TRUMPETERS (Any colour).—Silver Medal, J. H. Perrott.

SONG BIRDS.

CANARIES (Yellow without Crest).—First, Second, and Commended, Mrs. Hodder. Highly Commended, H. E. Bond.

CANARIES (Yellow with Crest).—Prize, H. E. Bond.

GREEN OR OTHER COLOUR.—First and Second, A. Veitch (Green Canary and Pied). Highly Commended and Commended, H. E. Bond (Harlequin and Lizard).

GOLDFINCH MULES.—First, J. Dowling, jun. Second, J. Fitzgerald. Highly Commended, W. P. Harris. Commended, Mrs. Hodder.

LINNET MULES.—Prize, W. P. Harris.

BLACKBIRDS.—Prize, Mrs. Hodder.

THRUSHES.—First and Highly Commended, J. Fitzgerald. Second, Mrs Hodder.

SKYLARKS.—First, Mrs. Hodder. Second, J. Perry.

BULLFINCHES.—Prize, J. Dowling, jun.

GOLDFINCHES.—First and Second, Mrs. Hodder. Highly Commended, T. Crowley. Commended, R. Russell.

LINNETS.—First and Highly Commended, R. Russell. Second, Mrs. Hodder.

SOCIETY'S MEDAL TO THE WINNER OF THE GREATEST NUMBER OF POINTS.—Mrs. Hodder.

WOODBURY HIVES.

UNDER the above heading at page 40, No. 302. of this Journal is a description of an "improvement" in the Woodbury hive, signed "C. F. George."

Any suggestions or improvements having for their object the facilitating the removal and interchange of bar frames in hives must, doubtless, be acceptable to all practical apiarians. Simplicity, however, should be the guiding rule in all improvements, whether intended to apply to things actually in existence or to those to be newly constructed. Mr. George states in his communication, "I have tried it, and it quite answered my expectation." Without in the least wishing to prejudice him, or in any way to detract from the ingenuity of his plan, I cannot but think that it is rather complicated. I would venture to inquire whether he has ever heard of the elongated top bar frames as first, I believe, introduced to public notice by "SIBERT-IN-THE-WOLD," in THE JOURNAL OF HORTICULTURE, No. 262, page 265, where it is fully described? It will be manifest from a perusal

of this article that the difficulty of loosening the frames when cemented by the bees is in a great measure obviated, and that the object can be effected without the necessity of thrusting the finger inside the hive. It was found, however, that the wooden notches which "SIBERT'S" bar frames rested in were liable to break in the process of moving the frames. Mr. Pettitt, of Snargate Street, Dover, has overcome this difficulty by the invention of a metallic-bar rest or rack for the reception of the ends of the elongated-bar frames, to which allusion is made by "SIBERT" at the conclusion of his communication above referred to, as also in an article signed "F. C. V." which immediately follows it.

The advantages of the metallic bars over the wooden notches are—1st, Their durability; 2nd, Their freedom from expansion or contraction from the effect of weather; 3rd, Their great simplicity and capability of adaptation to the Woodbury or Langstroth hives by the merest novice in the art of carpentering.

The elongated top bar has been ingeniously made applicable by Mr. Pettitt to existing Woodbury and Langstroth frames, and can be fixed to or removed from them as occasion may require by the most simple means. Thus, the interchange of combs between hives of the original and altered construction (required in the process of forming artificial swarms), is not frustrated.

The Sibert-Pettitt, if I may so term it, plan will be found to embrace, and with more simplicity, all that Mr. George appears to desire, with one exception—viz., "the frames can be gently pushed one towards another without lifting up." The force of this remark I cannot comprehend, inasmuch as the object of opening a bar-frame hive is the inspection of the combs. How is this to be performed without lifting the frames out?—X.

BEES CLUSTERING—MOVING HIVES.

I HAVE two common hives of bees in a bee-sbed, which does not answer, as the bees cluster in numbers within it during the summer without swarming. I wish to have the front taken out, and on its completion place the shed and hive 5 yards further back, and to the left of the original position the same distance. Can this be done with safety to the bees, and should the bees be moved gradually, a yard or so at a time, or at once? They will have to be put on common stands whilst the shed is altered.—INDUSTRIA.

[Bees often cluster outside their hives without swarming, whether kept in a bee-house or left exposed. The true remedy is either to super the stocks or form artificial swarms as may best suit your views. The stocks had better remain on the old spot until the season is sufficiently advanced to set them fairly at work, then move them very gradually—say a foot or so once a-week, until they reach the desired position.]

OUR LETTER BOX.

POULTRY SHOW AT BURY ST. EDMUNDS.—We are happy to inform our readers poultry will be exhibited at the Royal Agricultural Society's Show at Bury St. Edmunds, in July next, and a liberal prize list will shortly be published.

POULTRY CHRONICLE (*Lady Barn*).—It ceased to be published as a separate periodical in 1855, and was incorporated with our Journal.

RICE FOR FOWLS (*D. S.*).—Rice is not good poultry food. It is too poor, and has a tendency to produce vermin. It may be given at times for a change, but only in hot weather, and when there is abundance of natural food to counteract its ill effects. The only way in which it could be dressed to make it good food would be to boil it with meat.

FROST-BITTEN COMBS (*Subscriber*).—We have many fowls with their combs frozen, but none with legs so affected. We believe some will lose their nails, but we have none crippled by it. There is no cure for the comb, the frozen part must die off, and we should tremble for the frosted legs.

TURKEYS FOR BREEDING (*W. G.*).—We advise you to buy birds of last spring, or, if you like, a cock of 1865 and hens of 1866. If, however, any one keeps a cock in your neighbourhood you need not buy one. You can borrow him for twenty-four hours, or hire him, or send your hens on a visit to him. That is all that is necessary, and is as effectual as if you had as many cocks as hens. There is much similarity between Turkeys and sheep in this respect.

COCHIN-CHINA COCK'S EYES (*W. J. N.*).—There is an eye sometimes, found in Cochins called the "Jerry" eye. It is not a sightless eye to appearance, but it is so in fact when the bird becomes middle-aged. The celebrated "Jerry," the property of Mr. Sturgeon, handed down this only fault and his many virtues to his posterity.

VARIETIES OF COMBS (*M. L. A.*).—A *rose comb* is a double one full of points, like that of the Hamburgh. A *pea comb* is as it were made up of three single combs pressed into one, that in the centre being the highest, and having on each side the impression or projecting outline of the comb united to it by pressure. The *cup comb* is upright and single in front, it then divides; each side bows out in the centre and unites at the back, forming a cup. This comb is serrated all round. A hen will hatch Goose's eggs, but she does not cover many.

WORN-OUT SPANISH FOWLS (*J. E. S*).—The Spanish cock, seven years old, was worn out; the falling off of circulation, indicated by his discoloured comb, was a proof of it. We have no doubt he had a fat liver. This will often accompany a state of body in which the blood fills only one function—that of depositing fat. We have seen a young fowl almost bloodless, but so fat as to cause a cessation of all useful operations of the body. It was a Cochin pullet, and she looked like a badly-jaundiced patient in the face. We killed her by cutting her throat, but could draw only a few drops of thick blood. Had she lived a little longer these would have been absorbed, and she would have died from want of blood. We have never seen young Spanish die in this way, but they have diseases of their own. They are not long-lived, none of the non-sitters are, and few of the egg-producers reach the age of three without more or less of disease in the different organs having to do with the formation and laying of eggs.

EGG-PRODUCING FOWLS (*J. D*).—Brahmas, Cochins, and Houdans are the best layers. They are also very hardy. For a hundred fowls to do well you should have an acre and a half or two acres of ground. At present their food would cost you 25*s.* per week. Later, when there is natural food to be had, they would cost one-third less. You can keep them in a smaller place, but the above would ensure you greater success.

CROSS-BREEDING FOWLS (*Needy Subscriber*).—We do not approve of the cross between Brahmas and Houdans, because the latter are non-sitters. It is always bad policy to mate such with good sitters. Houdans are very hardy, they are capital layers, and will live as well in confinement as in an unlimited space. Dorkings want a large space. We think the cross you name between Brahmas and Dorkings will make you strong and good fowls, also excellent for table purposes. They will not be fit for the market at ten weeks; you must allow, even under favourable circumstances, six or eight weeks more. If you keep either Cochins, Brahmas, Spanish, or Houdans for eggs, they may be shut up in small places without detriment, and you will want your grass run for the hens and chickens. Till, however, the chickens are hatched the birds may run over it.

SCISSORS FOR DUBBING (*M. Y. Z.*).—You can buy them at any cutler's. The scissors used by grooms to clip horses answer very well for this purpose.

CATARRH IN FOWLS (*Gallus*).—Dry weather will be the best and almost the only remedy for the discharges from the nostrils. For many weeks we have had either rain or snow. The birds have lacked dust for baths and a dry surface for scratching. Continue the bread and ale and you will carry them on till they are cured by dry and perhaps sunshiny weather. We have never tried mustard, and cannot therefore give an opinion. We should not like to give much of it. We do not think there is any fear of crossing in the case you mention.

BRAHMA POOTRAS—BANTAMS (*Jem*).—There is no reason why a Brahma Pootra pullet running with a three-year-old cock should not produce good chickens. As you object to Game Bantams we recommend you to keep Gold-laced Sebrights.

TURKEY'S FACE SWOLLEN (*J. M.*).—It is certainly merely local, and neither hereditary nor infectious.

FOOD REQUIRED FOR FOWLS (*A. R.*).—The quantity varies with the season and the kind of fowl. Four pounds of barley-meal per week for each may be near the average. "The Poultry Book" contains directions for managing Ducks. (*M. L. A.*).—Your twenty-one fowls, besides the scraps you mention, should have five pints of meal and five pints of barley daily.

FOWL BREATHING WITH DIFFICULTY (*Lex*).—We believe that the symptoms you mention indicate catarrh, caused by the recent severe weather and subsequent rains. Generous food, with bread soaked in ale once daily, and confinement in a sheltered out-building, will be the best treatment. We consider roup contagious, and should remove entirely a fowl afflicted with it. Confining it in a pen in the fowl-house where the other fowls are we do not consider a sufficient separation.

PREPARING RUNTS FOR EXHIBITION (*Almost*).—Feed your Runts on good beans; they are believed to improve the colour and add to the gloss of the feather of Pigeons. Let them have a bath twice a-week, but not inside their house, as the floor will become wet and dirty, and the birds will soil their wings and tails. Of course you keep your loft scrupulously clean, removing all dung, &c., daily. We have blocks of wood, cut from limbs of elm, a foot across and a foot or so high, for the Pigeons to roost on. We place such a block in front of each two nests; then, the birds so roosting, the dung drops clear of them, and when the cock sweeps his tail on the pen it does not become dirty. If after the bath your light-coloured birds still look soiled, wash with soap and water, using a small sponge, and dry them in a basket littered with straw or hay by the fire. We recently wrapped up a washed bird in flannel to keep him warmer, and so that he should dry better, the weather being very cold. In Owls blue is the best colour, then silver, then any other. If black and white were equally well bred their value would be equal. It would be a mere difference of taste.

POUTER COCK ILL (*A Beginner*).—Separate your sick bird from the rest; put him in a clean dry pen where you can watch him; limit his supply of water; give him one grain of calomel three times a-week; then, if better, and if he be very thin of flesh, give a small dose of cod-liver oil once a-day. If you feel a lump of undigested food, cut open the crop, remove the lump, and neatly sew up the crop, having well cleaned it.

WORK ON BEES (*N. S. S.*).—A work such as you name was published once and failed. There are not enough readers. "Bee-keeping for the Many" may be had free by post from our office for five postage stamps. It was written by the late Mr. Payne, one of the best practical apiarians of our time, and has now many additions from former contributions to our columns.

LANARKSHIRE BEE-KEEPER.—The correspondent adopting this signature, answered in our last, was not "A LANARKSHIRE BEE-KEEPER" who occasionally contributes to our columns.

TOTAL MORTALITY IN A HIVE (*Mintlyn*).—It might have been better to leave the entrances unobstructed; but we believe it to have been just such an instance of "starvation in the midst of plenty" as was described by Mr. Woodbury in page 98.

REMOVING PAINT FROM AN AVIARY (*J. E. M.*).—Heat the paint strongly, and then it can be scraped off readily.

BOOK (*Old Beehive*).—"The Canary and Other Song Birds" contains all the information you seek. You can have it free by post from our office if you enclose twenty postage stamps with your address.

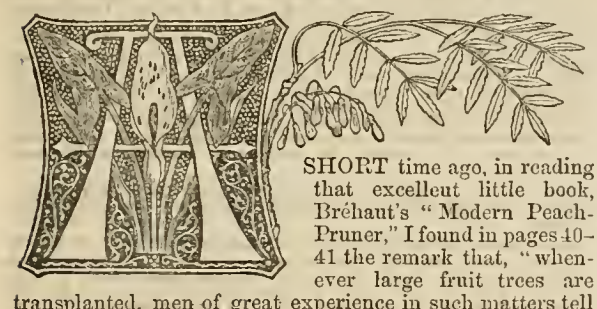
From observations taken near London during the last forty years, the average day temperature of the week is 45.3°; and its night temperature 30.7°. The greatest heat was 59°, on the 16th, 1863; and the lowest cold 2°, on the 17th, 1855. The greatest fall of rain was 0.51 inch. N.B.—The Calendar contains the names of plants flowering in the greenhouse.

TRANSPLANTING LARGE FRUIT TREES.



A SHORT time ago, in reading that excellent little book, Bréhaut's "Modern Peach-Pruner," I found in pages 40–41 the remark that, "whenever large fruit trees are transplanted, men of great experience in such matters tell us that the success of the operation depends mainly on the quantity of earth removed with the roots." Now, what I ask is this: Is it possible in removing fruit trees, such as Peaches, Plums, Cherries, &c., to do so with any considerable quantity of soil at the roots? and, again, if possible, is it necessary to attempt it, if care is taken to preserve the roots without mutilating or injuring them?

About five years ago I was living in the gardens at Oakley Hall, in Hampshire; great alterations were going on at that time, and the mansion was nearly rebuilt; the offices belonging to it have been replaced by a grand south front, and close to this, instead of a pond and lumber-yard, there is now a beautiful flower garden. About 80 yards from the south front stood the kitchen garden, and it was thought necessary to do away with it altogether, and turn it into the pleasure grounds. The place selected for the new garden was a meadow, about 300 yards westward, and the materials of the old walls were to be employed in building the walls for the new garden. Accordingly, about May or June, 1861, we began unnailing the trees, and tying them to stakes as far back as possible, to save them from being injured in taking the wall away. In the following October the new walls were so far completed, and the borders prepared to receive the trees. Mr. Robins, the late head gardener, intended planting all the trees from the old garden. They were large, fine trees, and I remember Mr. Robins telling me he found the Peach trees planted when he first went to Oakley Hall, about fifteen years previously; but as the borders had not been properly prepared, he had had the trees taken up, the borders made, and the trees replanted. They were then young, and I should fancy, by the appearance of the Plums and Cherries, they must have been all of about the same age.

In making the border great care had been taken to secure good drainage, and a firm bottom; a good layer of stones, about 8 feet square, with coal ashes on the top, was the foundation for each of the trees, which were then planted in good loam.

We began removing the trees by opening a trench, 2 feet wide, at 5 feet from the stem, till we came to the foundation; with steel forks we kept working the soil from the roots, taking great care to avoid injuring these in any way. The soil crumbled away from the roots as we gently ran the forks in, and we kept an open trench by throwing it out with shovels; it was in splendid condition, neither wet nor dry, caused, I suppose, by the good drainage beneath. As fast as we came to the roots we laid them up gently out of the way until we had traced them all out; then, one man taking the stem on his shoulders, and two or three supporting the branches, every tree, with the exception of the Pear trees, was taken to the new garden, the roots laid in the soil, spread out regularly, and a thin layer of leaf mould placed over them. The roots were all on one level, no tiers, and so evenly were they laid out that they might have been trained on the wall with as great regularity as the branches. Three very large Apricots were moved in the same way; one, I should imagine, was upwards of thirty years old.

The Pear trees were larger, and most of them of such size that men could not conveniently carry them, so we drew some of them to their destinations on low trucks. The old borders for the Pear trees had not been prepared in the same way as for the Peach trees; the soil was a rather retentive loam, and the roots had penetrated to various depths. Two years previous to the removal of the trees Mr. Robins had given them a good root-pruning, and where each root had been pruned there was a mass of small fibrous roots.

All I have to add is that out of all the trees (from sixty to seventy, I believe), not one failed, or looked in the least the worse for the transplanting. Most of them, with the exception of Apricots, bore fine crops of fruit in the first season. In this case, had we tried to have taken the trees up with soil we should have found it next to impossible. I daresay Mr. Robins could state the exact age and all particulars, as he had the sole management of them, I being then a youngster under him.—T. P. I.

VINE-GROWING.

In these remarks I do not intend to take up a position superior to those who have already stated their opinions, and to arrogate to myself the tone of a judge who has heard the counsel for both sides, and proceeds to sum up for the jury, but only to put on paper what I have for years been in the habit of doing for my own benefit—first reading with care what appears in your pages, and then making a comparison between what I then read and what has gone before, or, what is the same thing in the end, any other information I may have on the same subject; and I hope if my deductions are made in error some one else will explain to me where I go wrong.

In the first place, then, I consider the letters written on this subject are intended for one or other of two classes, and that this is the main reason why Mr. Wills and "A Gardener" on the one side differ from "H. S." and "Vitis" on the other. I call the system Mr. Wills advocates the "show system," where cost, commercially speaking, is not thought of, in the desire that when his bunches do come he will be able successfully to compete for the prizes at the London shows with even Mr. Meredith himself; whereas "H. S." and "Vitis" would, I think, be satisfied with a commercial success if they never took a London prize. By this term commercial success I mean a success equal

to the cost incurred; and as I am of their way of thinking I do with pleasure join in this discussion, which I hope may end in adding to our information, notwithstanding that we may each be of the same opinion still.

I do not wish from these remarks that Mr. Wills should think that, in classing him with those who advocate what I call "the show system" of Vine-growing, I intend to say that he for his own selfish reasons would put his employer to a greater expense than is required to supply his table with Grapes; but I am of opinion that the majority of the gardeners who lay-out gentlemen's gardens do not study this part of the question, but think it would be beneath them to produce a bunch that was not extra first-class, and they go to greater expense than is required in the hope that they can realise this. Now, I think the point in discussion is what part of such outlay is warranted, that extra care on the gardener's part will not replace; and I think that Mr. Wills, judging by what he says, would rather not run risks for the sake of saving the cost.

Having read Mr. Wills's paper, I turned to my geological map for the explanation of what he says of Bishop Stortford, that "there was no merit due to Mr. Nash or his gardener; the soil was there ready, and they could not help growing good Grapes." I find that that place is on the border land between chalk and London clay; will he explain at length what he means? Does London clay only want chalk added to make it so fertile? I simply do not think that the soil Vines are planted in is of such paramount importance, and that it could not under any circumstances reduce the gardener's care to a minor consideration. Of borders inside *versus* borders inside and out, I think the mere fact of there being an outside border attached to a vinery in which first-class Grapes have been grown should not be accepted as a proof of the advantages of outside borders; and I am sorry, as Mr. Wills was at Garston during the growing season, that he does not tell us that he examined these borders both in and out over their whole surface, and found everywhere feeding roots, as this could have been done without causing the Vines any injury. Mr. Wills complains of the Lancashire climate, yet he also tells us that Mr. Meredith does not protect these borders, but leaves them exposed to this adverse influence, notwithstanding that they are so important to his success. I must, therefore, retain my opinion for the present, that as the number of roots a Vine can support depends on the quantity of foliage that Vine has, any one who, after completing his inside border and getting it filled with good healthy roots, straightway proceeds by putting an outside border to his Vines, to encourage them to send out roots into this outside border, kills the roots that are in the inside border in direct proportion to his success in inducing them to go into the outside border; and that the only good reason for doing so in ordinary situations is to provide a means of supporting the Vines while he changes the soil in the inside border, that this, at times, important operation may be done at the least possible risk to the Vines. It is now some years since I visited the Garston Vineyard, and I have no recollection of these outside borders, nor do I see that Mr. Wills gives us their width and depth.

Mr. Wills speaks of obtaining 5*s.* a-pound for his Grapes, but I think he will not find in his climate that an outside border will assist him in the two periods when this price can be obtained, either very early or very late. He has hardly yet arrived at the full knowledge of how long-drawn-out a spring can be, and I hope when he sighs in your pages for sunny Cheshire he may be spared the taunts I once received; he is not now near Delamere Forest, or that cream of all Cheshire land, the valley of the Dee, but on the cold side of Pendle Hill, and I should think on the clays of the coal measures. The full extent of what this means cannot be told.

Let me now turn to the account of Vine-growing in the open air at Bury St. Edmunds that has lately been published elsewhere, as it leads me on to the last part of the remarks I wish to make on this subject, of which "H. S." speaks. Mr. Thomson can treat of the temperature required far better than I can, and as "H. S." has called upon him by name, I shall confine myself to the question of what is a "mean temperature," and try to arrive at the answer by induction. We gardeners should be very thankful to the kind meteorologists who compile the tables, and confer upon them what they for the most part look for as a reward for their trouble—the satisfaction of doing something useful. I can only impute to this desire the trouble they take in calculating out "mean temperatures;" and, while I acknowledge their claim as public benefactors, I cannot help thinking that when these alone are given, anything more likely to mislead could not be invented. "H. S." gives us as his idea of Vine-temperature the 45th degree of north latitude, with a mean temperature of from 70° to 73°. Let me, then, take France with these conditions. As far as I am informed the island of Madeira forms the only exception of a wine-producing country that is not in some sort limestone; in France the vineyards are either upon the chalk, greensand, or oolite, as that at Bury St. Edmunds is on the chalk. The Vines are cultivated on hill sides upon terraces, which are formed by bringing down the soil at intervals, thus exposing the rock, or a rough wall built up to support the next terrace, to the full sun heat. At Bury St. Edmunds we are told the "shelter is perfect," "dry," "the Vines are planted against a wall 22 feet high," and "behind which rises a hill 90 feet high," that, on a November day, with a brisk wind blowing, "the thermometer stood at 76° in the sun," and "that in summer it often reaches from 80° to 90° in the shade and 130° in the sun;" and then the writer finishes by telling us that "the mean temperature is 50°." Question, If 50° give 130°, what will 73° give? No, I will not calculate that out; I will try again, and take the return of the Astronomer Royal for the month of June, 1866: mean of the month 62.6°; maximum in rays of sun 131.5°. Now, if 62.6° give 131.5°, what will 73° give? Is it 153.3?—a fancy calculation if you like, but one that carries with it more than a modicum of truth. I have given the mean as 62.6°, and the maximum in the rays of the sun at 131.5°; the maximum in the shade was 86.5°; but I should, to make a true calculation, take the mean of the year, as "H. S." does, and not the mean of the hottest month; though, till I know what the heat in the sun is in these countries, I hesitate to give it as a fact that they have 153.3° in the sun. The mean temperature for the year in London will be nearly the same as at Bury St. Edmunds, and may be taken at 50°, and we may also accept his estimate of 130° as correct, corroborated, as this shows it to be, by the return of the Astronomer Royal.—G. H.

CULTIVATION OF THE CAMELLIA.

The following is a brief outline of my experience in Camellia culture, and it tends to prove that Mr. Pearson's system of cultivating that shrub is the best.

Having during the last two or three years, at stated times, received from Mr. Pearson about fifty Camellias of various sizes, I knew that they had been grown in the compost he recommended in your Journal of February 27th, 1866—namely, turf thinly cut from a sandy loam used when fresh. Several gardeners in my neighbourhood saw these plants on their arrival from Nottingham, all of whom testified to their remarkably healthy appearance.

Following up Mr. Pearson's mode of treatment, about the end of February, 1865, I repotted about twenty young Camellias and a few old ones, that had been out of health, in the compost above mentioned. The result was, that both young and old plants grew most vigorously.

In the succeeding February I repotted about twenty-five or thirty Camellias, including large and small plants, in the same compost, using it rougher for the larger plants. For the latter the turf was pulled by hand into pieces about 1½ inch square, and for the smaller plants pieces about half that size were used. In potting I press the turf well down, and finish off with half an inch of finely sifted loam, which gives an even surface. The turf I employed was cut from a sandy loamy pasture that had not been broken up for a number of years; it was only 2 inches thick, and was used a few days after it was cut.

After potting, the plants were placed in a Peach-house from which frost was merely excluded, and where they have remained ever since. They were kept clean more by sponging the leaves than by syringing. The progress they made under this treatment was readily perceptible; they made strong shoots, some of which were 1 foot in length, with magnificent dark foliage such as has astonished both the nurserymen and gardeners who have seen them, and they have afforded me a succession of splendid blooms since October. Two well-known gardeners in this neighbourhood came here a week ago on purpose to see these plants, and said that they had never seen anything to equal the blooms for size, substance, and brilliancy of colour.

I may here state, that I have for the last two years been a successful exhibitor of Camellia blooms at the St. George's Hall Shows, Liverpool.

As an instance of the effect of Mr. Pearson's compost on

Camellias, allow me to mention the remarkable growth which one small plant of the sort named Targioni rosea made in one year. I received it from Mr. Pearson last February, in a three-inch pot, with only one shoot from the graft, which was about 8 inches long. I immediately repotted it in a five-inch pot, using fresh turf pulled into small pieces with the hand, and now it has six fine shoots, averaging 6 inches in length, as well as three fine blooms.

I see at page 216 of the Journal, published on the 20th of last March, that Mr. Robson, in commenting on Mr. Pearson's article referred to at the beginning of this paper, is inclined to disagree with him about the soil he recommends, and goes on to say that he is "of opinion that the water a plant is fed with exercises as much influence on its well-doing as the soil it is grown in." Taking what has come under my own observation as a criterion to go by, I hope Mr. Robson will not think me presumptuous if I beg to differ from him, for I am of opinion that the time is approaching when such ingredients as peat soil, leaf mould, &c., as forming part of the compost considered essential for growing the Camellia to perfection, will be numbered among the things that were. I quite agree with Mr. Robson in his partiality for rain water; but I have watered Camellias with hard water which had remained in the tank for some time before being used, when rain water could not be procured, and the results I have above described have been obtained notwithstanding.

In conclusion, after my experience of nearly three years in Camellia-growing in turf soil, I feel quite convinced that I have witnessed a most signal proof of its superiority over any other system. I agree with "T. L. C." in what he says about soil for Camellias.

The dimensions of some of my Camellias, measured above the rim of the pot, are as follow:—

Bealii, 6½ feet by 5½.	Fra Arnoldo di Brescia, 5 ft. by 4.
Do. 5¾ feet by 4½.	Aulica, 3½ feet by 2½.
Mathotiana, 4½ feet by 3.	Countess of Orkney, 3½ ft. by 2½.

I am told that some of the above specimens are the best in England of their kind. They are dense compact plants, with branches growing down over the rims of the pots.

Having said so much about Camellias, another fact has come under my experience respecting greenhouse Azaleas, which I hope you will allow me to record. I have upwards of forty Azaleas, the majority of which are young plants, varying in size from 1½ foot by 1 foot to 3 feet by 2, although I have one or two 4½ feet by 3, measured above the rim of the pot. In June, 1865, they wanted repotting, and good turfy peat being a scarce commodity in this locality, I had recourse to turf cut about 2 inches thick from a loamy pasture, and which had lain in a heap exposed to the atmosphere for six months, adding a fair proportion of sharp silver sand. In this compost, then, I shifted my Azaleas. They were afterwards kept in a warm greenhouse and frequently syringed, and the amazing growth they made during that and the following season surprised not a few; there is likewise a decided improvement in the flowers they have since produced.

It is but fair to add that it is Mr. Pearson to whom I am chiefly indebted for my acknowledged success in the cultivation of the Camellia here; but I have not had the "wrinkle" about the Azalea from him, if "wrinkle" I may call it. I am aware that in some of the metropolitan nurseries they are in the habit of using something like one-half turfy loam in their compost for the Azalea, but I have never heard it recommended to use turf entirely. It is not, therefore, without some misgivings that I hazard the above startling assertion in the face of the entire gardening community. I may naturally expect that some Azalea grower who has had more experience than myself will come forward to confute what I have here advanced; if so, I must then endeavour to work up my writing powers in order to make an effort to stand the brunt of his attack single-handed, for I have had a plain practical proof of the utility of turf soil for Azalea culture.

The following is a list of some of the Azaleas and Camellias I grow here:—

AZALEAS.

Adolphi flore pleno.	Duke of Devonshire.
Barelayana.	Gledstanesii.
Broughtoni.	Purpurea magnifica.
Brilliant.	Præstantissima.
Criterion.	Prince Albert.
Delicatissima.	Roi Leopold.
Duchesse Adelaide de Nassau.	Smith's Grandis.
Danelsiana purpurea.	Stanleyana.
Dilecta.	Symmetry.

CAMELLIAS.

Amadryas di Cuzano.	Imbricata.
Aulica.	Jenny Lind (a beautiful variety).
Alexina.	Mahomet.
Bealii.	Mathotiana.
Countess of Orkney.	Marchioness of Exeter.
Comtesse Boutourlin.	Ochroleuca.
Cup of Beauty.	Queen of England.
Countess of Ellesmere.	Queen of Denmark.
Duc de Bretagne.	Roi Leopold.
Double White.	Rubini.
Donckelaarii.	Storyi.
Fimbriata.	Targioni.
Fra Arnoldo di Brescia.	Targioni rosea (fine variety).
General Dronot.	Teutonia.
Gutbriana.	Valtevaredo.
Herbertii.	

—R. Fleming, *Hopeton House, Seaforth.*

AN ORANGE-HOUSE IN JANUARY.

I had the unexpected pleasure, a few days since, of a look into a neighbour's house devoted to the culture of dessert Oranges. I have seen many conservatories gay with forced flowers in this month, but never anything in gardening more beautiful and interesting than this collection of Orange trees in full bearing, not only of fruit but flowers; the scene seemed so enlivening, so full of the sweet south, to which the agreeable temperature of 65° largely contributed.

The house, which is about 12 feet wide and span-roofed, is heated by eight four-inch hot-water pipes, four on each side. Two on each side are on the floor of the house, and covered with slates, so as to form a surface gently heated, on which the pots stand; and two on each side are above the surface, so that the air of the house can, when required, be thoroughly heated. The path is in the centre, and one border is filled with Tangierine Oranges mostly in pots; a few planted out grow with extraordinary vigour, but do not bear so freely while young as those in pots. The other border is filled with the sorts that bear large fruit, such as the Maltese Blood, St. Michael's, and others. The Tangierine Oranges, which commence to ripen in October, were nearly over, with the exception of a few which had been retarded by placing the trees in a cool house in November and part of December—this delicious little Orange, it seems, may be kept on the trees in great perfection for five months by retarding—but the large Oranges were in full perfection, and nothing in fruit culture could be imagined more beautiful than the bright evergreen trees from which their fruit, like golden globes, hung so gracefully, with here and there a tree in full bloom filling the air with fragrance.

So much for the intellectual treat; but there are doubtless many of your readers who would like to know something about the sensual—viz., whether these tempting golden fruit are as good to eat as pleasant to view. I will, therefore, endeavour to describe what I tasted. I must commence with that sort which, like the Ribston Pippin among our Apples, is unrivalled among home-grown Oranges—the Maltese Blood Orange; and thereby hangs a tale, for it is found that Oranges from the same tree vary in colour, some having their flesh red, and others pale, like common Oranges. In 1865, after the hot summer, the Maltese Oranges here were all Blood Oranges; but this season the fruit from the same trees have scarcely any trace of the deep red tinge, except a few fully exposed to the sun, which are veined with red. As to the flavour of those I partook of, it was really exquisite, and quite unlike that of the imported Maltese Oranges, which is rich and sweet, but flat; while the flavour of those I had the pleasure of plucking from the trees on this frosty January morning was not only rich and sweet, but brisk, and the flesh most agreeably crisp, with a fine aroma. I felt when tasting them that I had never eaten any Oranges more delicious, even when plucking them from trees growing in that to us enviable climate—perpetual summer.

My attention was next drawn to Tangierine Oranges, some of which were still in perfection. There are three or four varieties of this pretty little Orange, which is only good when fresh from the tree. Their aroma is so volatile, that within forty-eight hours after being gathered they are comparatively flat, like the imported fruit sold in the fruit-shops in London in December and January. Some of your readers who have visited Lisbon and Malta may, perhaps, remember those charming Orange bushes, so plentiful there, with small leaves and covered with fruit. In the Lisbon gardens they seldom attain a height above 6 feet. The Maltese variety, called in that island the Mandarin, seems more robust in its habit, and its fruit is larger and more compressed than its relative the true

Tangierine. One need not, however, talk of the true sort, for there are many varieties in existence differing slightly in the shape of their fruit and the habit of the trees.

I saw here what is called the true Mandarin Orange direct from China. In habit the trees are more erect than the Tangierine; their fruit is compressed and of the same size as that sort, but so acid as to be uneatable. The trees are most prolific, and are pretty objects, commencing to bear when only 9 inches in height. Tangierine Oranges, evidently seedling varieties, vary in shape. My neighbour thought those small and spherical in shape, with very smooth rinds, the most delicious. I tasted only those rather large and much compressed, such as I have bought in London as Mandarins, and found them full of rich juice, and the essential oil in their rinds so abundant as to spurt forth and perfume the air of the house.

The most remarkable variety of the Tangierine Orange has been received from the Azores. Its leaves are narrow and pointed; its habit more rigid and fastigiate than that of other varieties. Its fruit, nearly globular, is small, with a thin smooth rind, and its rich juice most abundant and refreshing. A fruit of this sort, divested of its rind, and taken whole into the mouth, is what the Romans would have called a gift from the gods, and Horace would have written a volume in its praise. This sort has doubtless been originated from seed in the Azores, and there are in all parts of the Orange-growing world varieties of this race, in some places called Mandarin, and in others Tangierine Oranges. There is no doubt about its being a race, for if thousands are raised from seed they all retain the habit of the type, and, like seedling Green Gage Plums, vary from stems covered with small leaves and thorns to others thornless, still with a strong family likeness.

After much tasting and a long discussion about Tangierines, we turned our attention to the Oranges called St. Michael's, many of which were growing on young trees not more than 18 inches and 2 feet in height. It did, indeed, look interesting to see these little fellows staggering under the weight of three or four large Oranges. Like the Tangierines the St. Michael's vary much in shape, size, and thickness of rind, and, as may be found in foreign Orange gardens, no two trees bear fruit exactly alike, unless they are under a careful grower, who plants grafted trees. In the course of time, when dessert Orange culture shall be an established luxury in England, the thin-rinded and sweetest sorts of St. Michael's will be carefully selected and cultivated. Those I partook of with my neighbour were full of juice, and crisp and rich, very unlike imported fruit. One of the finest varieties of this race is the Silver Orange, an oval fruit, not large, with a smooth pale rind, and with firm crisp flesh, remarkably full of juice, of a high flavour, and without pips. The Egg Orange, another variety of St. Michael's, is a large sort, of a very loose texture, sweet, and very juicy: this sort is a great bearer. The White Orange is also a very large fruit with pale flesh, very juicy and good, but not so rich as some of the above.

One of the most ornamental sorts of the St. Michael's is the Variegated Orange with white-edged leaves, bearing oval fruit, below the medium size, of a pale lemon colour striped with green. This sort retains its fine brisk flavour all through April, and when fully ripe is most delicious. In looking through the house I found fruit of the Sweet Lemon and Sweet Lime quite ripe; their flavour is sweet but flat, with a powerful aroma seemingly like musk. A very beautiful tree of a sort called the Prolific Orange was loaded with fruit, which was rather small, with a thick rind. This is a very late kind, and hangs through a great part of the summer. The tree is very ornamental, its fruit juicy, very sweet, and slightly bitter. Trees of the Bitelma and Embigero Oranges were in the house, and described as giving fruit of fine quality, but they were fruitless.

A curious fact connected with dessert Orange culture was mentioned by my friend: if in midwinter the trees with ripe fruit on them are exposed to a low temperature, the fruit to a great extent lose their juice; on the approach of warm weather, or if the trees be placed for a week or two in a high temperature, they recover it.

I confess that I could now realise the facts before me, I mean the tasting and trying so many kinds of Oranges gathered from trees growing in our own country; and I was told that many other kinds that have not yet borne fruit are likely to prove interesting.

The method of cultivation seems very simple; the four surface-pipes are alone used from May till October. Early in the last-named month the water in the four border-heating pipes is turned on and continued till the end of May. The extra heat in autumn and winter is required to ripen the fruit and bring on the blossoming time, which is in February, although many trees produce their flowers in December and January. A constant gentle artificial heat is required during summer, and stronger heat in winter, to keep the temperature as much as possible like that in which Oranges ripen perfectly in the open air. In winter, in the house I have been inspecting, the temperature varies from 45° and 50° by night to 70° in sunny days; in summer it often rises to 90° or 95°, even with abundance of air.

The scale, that great pest to Orange trees, is killed by using methylated spirits of wine, containing 4 ozs. of shell-lac to the gallon, now called by Act of Parliament "methylated finish." This is cheap, being sold wholesale at from 5s. to 6s. per gallon. It is perfectly innocuous, and a certain destroyer of scale. The black fungus on the leaves, which often appears in winter, is washed off with a sponge and warm water; and aphides, which in spring often infest the young shoots of Orange trees, are destroyed by tobacco smoke. On inquiring if bottom heat was absolutely necessary, and if four pipes arranged on each side of the house, as usual with forcing-houses, would answer the purpose, I learnt that Oranges would ripen well without it, but that constant artificial heat was required to make the climate of the proper ripening temperature.

I have been tempted to give you an account of all I have seen and learned about dessert Orange culture—1st, Because I was much delighted with all that I saw; 2nd, I do not remember that it has been treated of in your columns; and, 3rd, it seems to open a new and agreeable path of pleasure to those who love gardening.—Citrus.

ROYAL HORTICULTURAL SOCIETY.

ANNUAL GENERAL MEETING.

"There's life in the old dog yet!" shouted the stalwart Highlander from the bottom of the precipice over which he had been slung to recover his faithful hound; and "there's life in the old Society yet!" shouts many a stalwart horticulturist who has been waiting with patient anxiety the result of this last Anniversary Meeting. Who would have ventured to predict four years ago—yea, one year ago—that at the Annual Meeting of 1867 the Council would announce that by care and economy the expenditure of the Society had all but been met by the income? Let those who are constitutionally haunted with evil forebodings read attentively the Report of the Council which we this day reproduce in our columns, and consider if the time has not arrived when they may take courage and look cheerful. We can quite believe that is not an easy thing for some to do. The Society has been long in the state that everybody attempted to nurse it, though having no qualification for the office, and what with neglect during one part of its existence, and mismanagement during the other, it could not be otherwise than in the worst possible position. Those, therefore, who had an interest in its welfare had become accustomed to look upon it as a weakly-constitutioned body that was ever in imminent danger of falling; and hence they have suffered so long from chronic nervousness and anxiety, that one can easily imagine they will have some difficulty in realising the present favourable change in the condition of the Society.

We quite believe we have seen the worst. The direction has fallen into the hands of a Secretary who has a clear perception of the power and value of the respective sides of the ledger, and who is applying that faculty to work out the Society's regeneration. The first paragraph of the Report is reassuring, when it states that the income arising from Fellows' subscriptions is over £200 more than last year. Then the rent arising from letting space in the arcades is 80 per cent. more than was derived from the same source in 1865. The sales of garden produce from Chiswick are also much in advance of last year, and would certainly have been very much more had the fruit crop not been almost an entire failure.

The most perfect harmony pervaded the Meeting, and all who were present expressed themselves highly gratified by the improved aspect of affairs. There was only one circumstance which gave rise to a feeling of regret, and that was the conversation which took place in reference to the relation existing between the Society and the Committee of the International Horticultural Exhibition. So as fully to understand all the circumstances we must refer our readers to the report of the meeting, which will be found below. Sir Wentworth Dilke has clearly been under the impression that no such arrangement

as that referred to was made with the Council, and has acted with perfect consistency throughout; but the production at the Meeting of Mr. Wilson Saunders's memorandum made at the time the agreement is said to have been entered into, is so conclusive that we have no doubt but that a misunderstanding has existed on the matter; and the subject merely requires to be properly represented in the right quarter for an amicable settlement to be effected. It is much to be regretted that Sir Wentworth Dilke was not present at the Meeting, when he could have answered the statements that were then made.

The Annual General Meeting of the Royal Horticultural Society was held on Tuesday last, the 12th inst.—His Grace the Duke of Buccleuch, President of the Society, in the chair.

The Assistant Secretary (Capt. Cockerell), read the advertisement convening the meeting, and then the minutes of the last General Meeting, which were confirmed.

The President then requested Messrs. Fortune and Booth to act as Scrutineers of the Ballot for the election of Members of Council and Officers.

The Assistant Secretary then read the following Report:—

REPORT OF THE COUNCIL.

"1. Notwithstanding the monetary distress of the past year, the Council are able to report to the Fellows an increase in the amount of annual subscriptions. The sums paid by Fellows as subscriptions in 1865 amounted to £7975 1*s.* 1*d.*, and, as will be seen by the annexed statement of receipt and expenditure, their annual subscriptions rose to £8176 9*s.* 6*d.* in 1866.

"2. The rents for the arcade-lettings to horticultural implement makers have also increased more than 80 per cent. since the year 1865, and during the last twelve months £320 have been paid to the Society under this head, in addition to the sum of £149 17*s.* received for Her Majesty's Commissioners of 1851 for the stalls in the south-eastern arcade.

"3. The sales of garden produce from Chiswick for 1866 have likewise exceeded those of the previous year. In 1865 these sales brought in £650 3*s.* 8*d.*; in 1866 they amounted to £717 15*s.* 5*d.* But for the failure of a considerable portion of the fruit crops—a failure under which all gardens in and about London suffered—the receipts from this source would have been considerably greater.

"4. It will be seen, therefore, that in the sources of income least liable to fluctuation the Society has made decided progress; and although the receipts from exhibitions and for daily admissions have fallen considerably below the average, the Council are of opinion that the affairs of the Society, though requiring strict economy, are in an encouraging position, for these deficiencies are traceable to causes which have affected every undertaking, whilst the progress made can only be attributable to the increasing popularity of the Society, and to the daily increasing number of wealthy residents in the neighbourhood of the Gardens.

"5. The falling off in the receipts for exhibitions and admissions to the Gardens is in part also attributable to another cause, which will not probably be of frequent recurrence. Although a payment was made to the Society from the funds of the International Horticultural Exhibition—and this payment was equivalent to that which is generally cleared by the First Great Show of the Society, the place of which it took—it by no means represented the whole diminution which it occasioned, directly and indirectly, to the receipts of the Society. It was proposed, when this arrangement was made, that the International Exhibition should be open for four days only, but at the end of the four days its receipts fell so far short of the anticipations of its promoters, that they found it necessary to apply to the Council for an extension of the time for which the Gardens were granted. The Council, in the desire of saving from heavy loss those who had so liberally given their names as the guarantors of an undertaking devoted to the interests of horticulture, at once acceded to the request, and, from the serious financial failure which it threatened to become, the undertaking was converted into a brilliant success.

"6. A further deficiency in the receipts, as compared with those of 1865, was occasioned by the abolition of the cheap admissions, in compliance with the wish expressed by the Fellows at the last annual general meeting, and unfortunately the free admissions which were granted to the public in lieu of them, were not so successful as to induce the Council to repeat them. They were taken advantage of less by the classes for whom the boon was intended than by those whose presence in the Gardens the Council had no desire to encourage.

"7. It may be remembered by the Fellows that the library of the late Dr. Lindley was last year announced for sale, and a proposition was made that the Fellows of the Society should be invited to subscribe for its purchase. The Council, however, having been given to understand that its purchase was contemplated by the Committee of the International Exhibition, thought it needless to bring it before the Fellows. Pending a decision concerning the mode in which so desirable an object was to be attained, the Council decided to advance the money for it, and they have now reason to believe that a portion of the surplus from the International Exhibition will be applied to the formation of a horticultural library at South Kensington, commencing with the purchase of the Lindley Collection.

"8. In carrying out the scheme for the year's arrangements, the Council have reduced the expenditure wherever it could be done without impeding the effective working of the Society, and an analysis of the accounts put into the hands of the Fellows will show that the strictest economy has been exercised. The expenditure for the maintenance and improvement of Chiswick, and for assistance given by the scientific staff, will hereafter yield its due return in increased produce in the Garden and in reputation to the Society, whilst to have stopped the work which is being so ably carried on would have been very injurious to it. For full information on this head Fellows are referred to the annexed report of the Chiswick Board. In speaking of Chiswick Gardens, the Council think it right to call the attention of the Fellows to the fact, that Mr. Thompson has now for a period of forty-five years rendered very valuable services to the Society, the greater part of the time as the Superintendent of the fruit and vegetable department. His great age requires that he should now have some rest from his labours, and, pending the adoption of any ulterior measures that may be taken for his advantage, the Council propose to continue to pay him the full amount of his present salary, leaving it to himself to determine what he can best do to assist the Society.

"9. The Education scheme for gardeners is working with success. The examinations held this year have resulted in thirteen young men receiving certificates either for horticulture or fruit and vegetable culture. Five of these gardeners are employed at Chiswick, five at the Royal Gardens at Kew, and three were from private establishments. Of those who presented themselves for examination, three had previously obtained certificates or prizes from the Society of Arts, examining on behalf of the Royal Horticultural Society. Two also showed themselves worthy of election as Associates.

"10. In their arrangements for the present year the Council have been induced to try the experiment of extending the duration of the First Great Show to four days, and the principal exhibitors have promised their support in making the experiment a success. It is proposed to hold the greater part of the Exhibition in the Great Tent and in some additional canvas-covered spaces. The more delicate plants will be shown in the Conservatory.

"11. Relations have been entered into with the Royal Agricultural Society for holding an Autumnal Fruit and Flower Show in the provinces in connection with their annual Agricultural Show, and arrangements have been made with them for a conjoint Exhibition at Bury St. Edmunds in July next. The horticulturists of that place and of the adjoining counties have entered into the scheme with a degree of spirit which indicates that the guarantee from loss stipulated for by the Council as a condition of holding the Show is not likely to be called into requisition. In a very few weeks from the announcement of the Council's intention, the contributions to the guarantee fund amounted to double the sum named as necessary; and, in addition to the prizes offered by this Society, cups, &c., to the value of no less than £226, have been offered by towns, counties, flower societies, and private gentlemen. The Council confidently expect, therefore, that the Show at Bury will not only exercise a beneficial influence on horticulture, but that it will conduce also to the reputation of the Royal Horticultural Society.

"12. It was originally the intention of the Council to publish four numbers of the Journal annually, to be paid for by subscriptions from such Fellows as might wish to receive a copy of the work. The additional subscription did not, however, find sufficient favour with the Fellows to enable the Council to publish the Journal on this footing; and the Council, unwilling to give up a plan which appeared to them to be so important an aid to the objects of the Horticultural Society, have determined to do what is possible towards it by bringing out the numbers of the work at longer intervals, and supplying them at the expense of the Society to the whole of its members.

"13. These and other proposed alterations and reductions in the expenses of management will, it is hoped, effect all that is necessary in the way of saving, without intrenching on the privileges and the pleasures of the Fellows; but the Council desire to impress upon every subscriber the advantage to the cause of horticulture, of inducing his friends to take a warmer interest in the work of the Society, and to enrol themselves amongst its Fellows. No better way of effecting this offers itself than that of bringing them to visit the Tuesday Fruit and Floral Exhibitions of the Society. Under this belief the Council have given to the Fellows the fullest privileges for these Shows, and they have also raised the payment for admission to the Gardens on these occasions, to enhance the advantages which the Fellows' privilege of admitting friends enables them to confer.

"14. The Council are taking steps to get the tax removed from Tobacco purchased for horticultural purposes, and the Chancellor of the Exchequer has signified to the Council that he is very willing to receive a deputation of the Society on this subject. He will fix an early day for the purpose, and the deputation will be headed by the President of the Society, His Grace the Duke of Buccleuch. It is the intention of the Council to invite the leading horticulturists of the country to join in it."

REPORT OF THE CHISWICK BOARD.

"The attention of the Chiswick Board of Directors has, during the past year, been more especially directed towards restoring the Gardens to their former state of efficiency, so that little, comparatively, has been done of a strictly scientific nature. Some successful attempts at Hybridising, however, have been effected, the success of most of which is at present uncertain; one, however, a cross between the Ivy-leaved Pelargonium and some of the best zoned varieties, has been

happily accomplished, and it is hoped that out of the numerous seedlings some striking novelties may be produced.

"Attempts have also been made towards the cultivation of Truffles and different kinds of Mushrooms. The Truffle-bed has not yet been disturbed, but a better result than has attended other attempts is scarcely to be hoped for. It was, however, thought right that it should be tried on the best principles; and should it not succeed, they will not be deterred from further attempts. So little at present is known of the growth of Truffles in the infant state, that we must be content to work a good deal in the dark. As regards the Mushrooms, it cannot be known till next autumn whether any success has been obtained.

"A valuable series of observations on Radiation, and other cognate matters, has been made at the suggestion of Mr. Hadwen, which will shortly be published in the Journal.

"Great pains have been taken in verifying some of the doubtful plants in the collection.

"The Directors feel great pleasure in reporting the great success which has been achieved, as regards making the Gardens a school of Horticulture, by the employment of students in the work of the Garden. The results of the late examination are also very encouraging, and they think it may be advantageous, both to the Society and to young men entering on the profession of gardening, if the number were extended as opportunities permit.

"Pomological Section.—*Fruit Department.*—With the view of continuing the experiments in the comparison of the numerous varieties of fruit now in the collection at the Garden, and especially in the vast number of Vines, the glazed wall was converted a few years ago into an experimental vinery, where all the varieties are trained against the wall on the 'single rod' system, by which means no less than 128 varieties have been planted. The last was the first season in which any great number of these Vines produced fruit, and many important observations were made which, however, it would be premature at present to announce, until they have been confirmed by the experience of another season. It is believed, from what the Board have seen, that many of these so-called new varieties will prove to be old kinds under new names, some will be found to be entirely worthless, while not a few must become useful and permanent additions to those already in cultivation.

"Great confusion exists among the large section of Grapes included under the name of Chasselas; and for the purpose of throwing as much light as possible on the subject, plants of all the varieties known to belong to that section have been propagated and grown in pots; and in the ensuing year the whole collection will be fruited, and many points on which much doubt has hitherto prevailed will be cleared up, and this important section of the Grapes will be reduced into proper order.

"Another very important subject which has engaged the attention of the Board is the collection of Figs, of which there are now seventy-four varieties in the Garden. Since the last Report was made, the house in which the Figs were usually grown has been entirely reglazed; every alternate sash-bar has been removed from the lights, and the small squares of dirty glass, with their numerous overlaps, have been supplanted by squares of large dimensions, thereby introducing a flood of light, which is essential to the successful perfecting of the fruit of the Fig. Considerable progress has also been made in the identification of old varieties under new names, and in the fruiting of others that have not hitherto been introduced to this country; but, as in the case of all new fruits, great caution is required in coming to any conclusions on the subject, and, therefore, before any report is made, the Board consider it judicious to repeat their observations another season, when, judging from the promising appearance of the trees, they expect to derive greater facilities for coming to a satisfactory conclusion than have hitherto been afforded.

"For the last few seasons repeated attempts have been made to investigate the collection of Strawberries, but without effect; the plantation which existed in the Garden having, in common with others throughout the country, suffered from the successive effects of late spring frosts and summer droughts, it became necessary to form an entirely new collection, including in it all the varieties that were known to exist either in this country or the Continent. Through the liberality which always characterises the nursery trade in its relations to the Society, the Directors have the pleasure to report that the new plantation, which has been formed on a newly-prepared piece of ground, now includes no less than 286 varieties, and it is hoped that in the year 1868, should no untoward event arise, a rare opportunity will be afforded to the Fellows of the Society and those interested in the subject to study this extensive collection.

"It has been found that the old collection of Apples on Paradise stocks, which occupies the borders of the orchard and kitchen garden, and which is coeval with the existence of the Garden, is rapidly falling into decay, and although by certain treatment the trees might be renovated and rendered healthy and fruitful, the expense and labour that would be incurred in arriving at this result are so great that steps are being taken to gradually remove these old trees and to form a new collection with others of a younger and more healthy growth. Another and perhaps the greatest objection to the continuance of these trees is the fact that most of them are grafted with several distinct varieties, which in many instances have been double-worked, and the evil results that arise from this circumstance, where so many applications for grafts are furnished to the Fellows from these trees, are in themselves sufficient to justify the course which the Board propose to carry out. Every care has been taken to preserve the full collection, and, in anticipation of the destruction of the old trees, scions have been taken from them, and these being worked upon stocks, have now grown into handsome young trees ready to take the place of their predecessors.

"During the past season the Plum and Cherry crops have been an entire failure, and for all practical purposes have been productive of no useful result. The great uncertainty there is in securing a crop of Cherries, whether from the damage done to the bloom by late spring frosts, or by birds when a crop has been obtained, has induced the Board to institute a course of experimental examinations by growing the trees in pots and cultivating them under protection. This appears to be the only alternative where a large collection has to be dealt with, and where it is impossible to protect every individual tree when out of doors. The Board, therefore, propose in future to grow all new varieties that may be received, in pots, and to add to them when young trees can be obtained all the old varieties in the garden, so that future experiments may be carried out with some reasonable prospect of success.

"Every opportunity is taken of securing the novelties which are announced, and it is the object of the Directors to render the collection of fruits in the Chiswick Garden as complete as it is possible to be, so that it may become a centre of reference upon all subjects relating to fruits and to fruit-tree culture. It is with much pleasure that they have to record the great liberality of the Rev. John Huyshe, of Clysthydon, near Exeter, who has been the successful originator of several valuable varieties of Pear bearing his name. Among these varieties was one of unusual size and excellence, which has been named Huyshe's Prince Consort, and the entire stock of that variety Mr. Huyshe has placed at the disposal of the Society. Upwards of a hundred young trees have been propagated of it in the Garden, and these, along with two or three hundred scions sent by Mr. Huyshe, have been distributed in the first ballot of this year.

"It is gratifying to see the unabated interest which the nursery trade, and others connected with the pursuit of horticulture in the country, manifest in the maintenance and success of the operations at the Garden, as exemplified in the liberal donations of any novelties they may possess, and the desire that the Society should have an opportunity of comparing, examining, and proving the various subjects of horticultural interest. It is also an encouraging sign, and an evidence of the important services the Society can render to horticulture, to find so many applications from so many of the professional as well as amateur Fellows of the Society for scions and seeds of fruit and ornamental trees, either for the augmentation of their collections or for the careful preservation of the nomenclature of the subjects of which these collections are composed.

"*Vegetable Department.*—In the Vegetable Department the experiments in proving the varieties of new vegetables and comparing them with the old have been continued. In the past season the Board resolved to investigate the varieties of garden Peas, and with this view obtained, through the liberality of the nursery and seed trade, the seed of considerably upwards of one hundred sorts, all of which were sown on ground skilfully and carefully prepared. Unfortunately, however, the ravages of slugs and of other predatory insects, which resisted every means adopted to exterminate them, were such as to entirely destroy the whole crop, and this having occurred a second time with a crop sown after the destruction of the first, the desired result was not obtained. The attempt will be made again this season, when it is hoped that better fortune will attend their labours.

"The crops of which successful examinations have been made are Onions, Beet, and Celery, and of these the reports will be published in the Journal of the Society in due course.

"Floral Section.—As regards the Floral Department, while the supply of bedding plants for South Kensington, as well as of flowering and other ornamental plants for the decoration of the conservatory, has been maintained, other plants of interest have from time to time, so far as the glass accommodation has permitted, been sent from Chiswick to the Tuesday meetings and Saturday promenades. A new lean-to house has now been erected, and a second house is in course of removal from Kensington, for the purpose of more fully carrying out this latter object. These additions and some modifications with respect to the older erections, will not only much facilitate the keeping up of these several supplies, but will also give to some extent the increased facilities that were necessary for experimental cultivation, and for supplying plants for the ballot distributions.

"The cultivation of New Flowers for examination by the Floral Committee has been carried on as usual. In the course of the season, the trial beds have not only proved attractive to those who visited the Garden, but have afforded valuable information to many persons who sought it as to the habits, qualities and colours of the different plants. To the trial beds of former years was added, during the past year, a series of beds for the growth of examples of the now fashionable group of Sub-tropical Plants, so much used for summer garden decoration, and a very interesting collection of these was brought together. The thanks of the Fellows are due to those gentlemen who were good enough to contribute these various subjects, intended either for experimental culture or for purposes of public reference.

"A considerable space of ground, which had been previously prepared for the purpose, was during the past season planted with a choice collection of Conifers presented to the Society by Messrs. Veitch & Sons,

Messrs. Waterer & Godfrey, Messrs. Lee, Messrs. Osborn & Sons, Mr. Dancer, Mr. Standish, and Mr. W. Paul. When established, these will afford useful information to those gentlemen who may wish to make selections for ornamental planting. A collection of Roses was also contributed by Mr. W. Paul, Mr. C. Turner, Messrs. Rivers and Son, and Messrs. Wood & Son.

"It is yet too early to ascertain the amount of damage occasioned by the excessive cold to which the Chiswick Garden was exposed during the frosts of January 1867, but it is to be feared that half-hardy subjects will have suffered severely."

The PRESIDENT said the other Reports appended to that which had been read were in the hands of the members of the Society, and as they were rather long it would not be necessary to read them, every member having a full opportunity of making himself acquainted with their contents. They would, with the consent of the meeting, be taken as read (hear).

The Rev. GEORGE CHEERE then moved that the Report just read be received and adopted.

Mr. HARRY CHESTER said, before the question was put he wished to be allowed to make a few observations. The meeting was very satisfactory, and no one could fail to observe it as contrasted with their meeting of two years ago, when there was a great deal of excited opinion; but now quiet reigned, and excited feelings were gone. But though there was an improved condition of affairs, the meeting was not so numerous as on that occasion, when the room was filled. There were two points in the Report of great interest. In one of them he (Mr. Harry Chester) had taken a very great interest, having been the first, he believed, to bring the matter before the Society, and that was the education of gardeners. The scheme had been well received by the Council, and he had the pleasure of serving on the Committee, who investigated that and other matters. There were some who had doubts as to the possibility of the Council carrying out the scheme recommended by that Committee, but the majority were in favour of it. A very considerable portion of the scheme had been carried out, and it was satisfactory to find it had been attended with such excellent results. Nothing could be more important to the Horticultural Society than the education of gardeners, and he (Mr. Harry Chester) would be glad if some member of the Council would tell them more in detail what had been done, as the passage in the Report referred to it only in a very cursory manner, and he should like to know more about it. That was one point, the other was a matter that was referred to with a vagueness in the Report which he could not understand—he meant the relations that existed between the Royal Horticultural Society and the International Horticultural Exhibition. On that part of the affairs of the Society the Fellows were entitled to have more information. That Exhibition arose out of the visit of the Society's representatives to the Brussels International Exhibition. It appeared from the statements which had gone forth that the Royal Horticultural Society had treated the Exhibition Committee with great liberality, and it also appeared that an arrangement was made that under certain circumstances the gardens were to be kept open longer than had been agreed; a certain portion of the profit arising therefrom to come to the Royal Horticultural Society. It appeared that during the first four days of the Exhibition (the time fixed originally as the duration of the Exhibition), there was a complete failure, and instead of the Committee of the International Horticultural Exhibition having a profit, there was nothing but a loss, and, of course, the obligations of the management to pay expenses, would have been very great indeed. The act of the Royal Horticultural Society prevented that, which would have been a very great discouragement to future exhibitions. Now, the way he understood it was, that a proposition came from the Exhibition Committee through Sir W. Dilke—who, by-the-by, he (Mr. Chester) did not see present, though he wished he did. The Exhibition Committee sent Sir Wentworth Dilke to negotiate with the Royal Horticultural Society, and the Society gave them a chance of turning that into a great success which had been at its outset, and as originally projected, a failure. The Society agreed to open their grounds for another week, for which concession the Exhibition Committee were to pay all the expenses; if there was a loss the Society would not claim anything from the Committee, but if there was a surplus, then the Society were to have a portion of that surplus. Certainly that seemed a natural bargain, and one entirely within the limits and course of natural justice. This was agreed to by Sir Wentworth Dilke; a memorandum of the matter was made, and a minute drawn up, which was read over to him, and he received it before the Exhibition took place, and they (the International Horticultural Exhibition Committee) were bound by that which had been agreed upon and put in writing, and given to Sir Wentworth Dilke, the Chairman of their Executive Committee. But for the Society that Committee would have been large sufferers; they (the Society) had come forward liberally, and did that which had brought about the good result of a large surplus. Now what was to become of that surplus? Few persons knew even what it was. There was no doubt the money had been given by a great many people, and it was difficult to say what the Committee were to do with it, as could be easily done if it had been received for any well-defined purpose. Then they could not give it for anything else. It might, perhaps, be wise to keep it, and not do anything at all with it; for if it were a trust no power but the Legislature and the Court of Chancery could give the trustees power to alter the trust. Then the Managers of the Exhibition had thought proper to make a grant of £1000 to the Gardeners' Benevolent Institution, and though he (Mr. Harry Chester) did not know if there was any lawyer present, if there was, he would be glad to ask him if that grant was legal. He did not want to dispute it, that was not his object; he did not want to complain, but what he did want to say was, that there was still a large surplus, and did not the Committee intend to give the Society any of it? (hear and cheers). It seemed to him that according to the undertaking that had been entered into, that the Society ought to have some (hear). It was said that it was proposed to invest a portion of that surplus in the purchase of the Lindley Library. No doubt it might be desirable that should be bought, but he begged to say they had no right to do anything of the kind. It seemed to him (Mr. Harry Chester), that it would be only right that the surplus, or, at all events, some of it, should be handed over to the Society, and then by an arrangement it might be agreed between the Royal Horticultural Society and the Committee of the International Horticultural, that the Lindley Library might be purchased out of that surplus, and become the property of the Royal Horticultural Society. He spoke without having seen the Reports of the two bodies, and he hoped before the present Meeting proceeded to the final adoption of the Report that was now before them, that the members would be favoured with some explanation by the Council. There was another body who treated the International Exhibition Committee with great liberality. He (Mr. Harry Chester) referred to Her Majesty's Commissioners of the Exhibition of 1851, who gave the use of the ground without any charge, but they were not in a position to ask the Committee of the International Exhibition to give them any portion of the surplus, nor, indeed, did he (the speaker) suppose that they would; and, in fact, if they did the Commissioners would not take it, but the Royal Horticultural Society were indebted to the Commissioners, and if the Society could get any of that surplus, it would in their present financial position be of great use, as it could be handed over in part payment of the amount in which the Society were indebted to the Royal Commissioners of 1851. Possibly His Grace the President, or some other gentleman connected with the Council or with the Committee, would kindly inform the Meeting of the views entertained of what he (Mr. Harry Chester) had said.

Mr. EDGAR BOWRING, the Secretary to the Royal Commissioners of the Exhibition of 1851, said that if the question had not been raised, he should have felt it his duty to have brought it before the members of the Society in his capacity as one of the Fellows. He would just state the matter shortly, which was simply this: The Council submitted to the Expenses Committee their estimates of the receipts of the year 1866, and on that statement the Expenses Committee based their corresponding expenditure. They have no legal control over the application of their receipts, but they have over their expenditure. In the anticipated receipts there were three matters which they took into account—the exhibitions, the promenades, and the special fêtes. Now, the Society proposed to give up the Great Summer Exhibition from which a great share of the profit was derived, as they thought the public would get so *blasé* with shows that they would not care to go Then as to the special fêtes it was found that they really realised more than they were estimated at. Now the total estimate under these heads for the year 1865 was £2630, and for 1866 only £2180, or £450 less than in 1865, and it seemed that if the Society took a sum of £300 in return for the very large sacrifice they would sustain in not holding their Summer Show, and allowed this in the estimate, that would meet the case. Therefore the estimate was passed by the Expenses Committee with only the difference of £150, that being the absolute amount of difference between the two years. He (Mr. E. Bowring) would not deny that the bad weather necessarily affected the receipts of the promenades, though not to such a very great extent as might have been expected, because the class of persons upon whom the Society chiefly relied for that source of income had left town when the very bad weather set in. The Expenses Committee knew very well that as far as the special fêtes were concerned the funds must suffer very seriously, and it could not for a moment be denied or concealed that the monetary panic which had prevailed had made a great difference in the receipts. All those matters had been detrimental, and it was now found that the receipts had been £930 less than the estimate, and that being added to the amount short already indicated of £150, showed a deficit of £1080 as contrasted with the previous year. Then it seems that there arose a state of things which had never been contemplated by anybody, for the International Horticultural Exhibition, instead of being as at first had been anticipated a failure, had been by the action taken by the Royal Horticultural Society turned into a success, and the Committee found themselves with an unexpected surplus of £3000. Unfortunately, however, they were in the position of the Chancellor of the Exchequer, who having a surplus was applied to in all places and from all quarters, as His Grace, the President, would well remember had been the case with the Commissioners of 1851, who had the same difficulty in dealing with a surplus on a large scale. He (Mr. Edgar Bowring) was not a lawyer, but he had consulted some of his friends learned in that way (hear), and from them he had ascertained, that though the International Horticultural Committee had no legal right to do what they had done, no one had any power, or at least any right, to find fault with them for what they had done. The question under somewhat similar circumstances had been mooted as to the receipts of the Exhibition of 1851, but here it appeared that no one who had given anything was

entitled to have any control, having had the *quid pro quo*—the admission to the Gardens, and so on. The International Horticultural Exhibition Committee had given away the sum of £1000 to the Gardeners' Benevolent Institution. With regard to that grant there was no chance of its being impugned, or any fault being found with what they had done. Now, with regard to the Lindley Library, it was very important to the interests of the Royal Horticultural Society if it could be secured, but it would be a most disinterested act if it was paid by the Society out of the money which would come out of the *quasi* promises of the International Horticultural Exhibition Committee. If the Society obtained the Library, it would be better that it should not be held as the property of the Society, for fear of what might by any mischance transpire, and they would be better acting in the position of trustees, so that if by any mischance the Society should be broken up, it would still be a property available for the purposes and benefit of horticulture. Now, with regard to the acts of the International Horticultural Exhibition Committee they had a surplus of £3000. They had given £1000 to the Gardeners' Benevolent Institution, leaving £2000 in hand. Now if the sum of £600 was paid for the Lindley Library there would then be about £1400 left. No doubt there were some outstanding debts, which probably would amount to a few hundreds, so that there would still be a sum of about £1000 left, perfectly nett, with which they will not, as it appears, do what they ought to do. When the Council agreed to extend their time there was a great deficit, to avoid which they offered the *quid pro quo*. The Council think so, and I have reason to think there was a memorandum made as to the fact that if there was a surplus the liability to the Royal Horticultural Society should be fully acknowledged, that while all the monies should belong to the International Horticultural Exhibition Committee, if there should be a surplus, some portion of it should belong to the Royal Horticultural Society. It certainly did appear to him that if the Committee of the International Horticultural Exhibition considered how much their receipts had been affected by what the Society had done—when they saw that that which would have been a deficiency instead of the surplus which they had, had been obtained through the action of the Society, they would have acted differently. He (Mr. Edgar Bowring) would further say that at the meeting of the Expenses Committee, in passing the accounts and examining the statements, they did adopt a minute that the Society should have received a larger amount of compensation. There was another matter in which he thought there should be a more liberal concession by the Society towards those who had done so much for them. He spoke of the debenture-holders. There had been £50,000 raised, and they pay 4 per cent. Originally they paid 5 per cent., and there were free admissions to the amount of £2 2*s*. per annum; that made in reality 7 per cent. Subsequently it was agreed to take £4 per cent., receiving the same Garden benefits, or 6 per cent. instead of the 7 per cent. He (Mr. Edgar Bowring) thought there might be some arrangement by which the debenture-holders could be further recognised, and if they could have further admission—say to £4 4*s*. per annum, with £3 in cash, it would benefit the Society, and the debenture-holders would not be displeased. He begged to recommend that to the consideration of the Council.

Mr. HARRY CHESTER would be glad to know more with regard to the arrangements between the Royal Horticultural Society and the Committee of the International Horticultural Exhibition.

The DUKE OF BUCCLEUCH.—I think the best way will be to read the minutes—that will show that the matter has been under the consideration of the Council, and after the liberal way in which the Royal Horticultural Society has acted towards the International Exhibition Committee, if there be any surplus it ought to be handed over to the Society (hear).

Col. SCOTT said, the following was the memorandum made by Mr. Wilson Saunders at the time of his interview with Sir Wentworth Dilke:—

"All charges paid.

"Saturday to be 2*s*. 6*d*.

"Free entrance on Saturday to Fellows' transferable tickets.

"All moneys to be theirs, but in case of surplus a portion to be made over to the Horticultural Society."

Col. SCOTT continued by saying, that acting upon that as reported to be the result of the conference between Mr. Wilson Saunders, a meeting of Council was held, and the following minute resulted:—

"It having been arranged that the International Horticultural Exhibition should remain open until Thursday next, the 31st May, the Council agree to allow visitors to the Exhibition to have access to the Society's Gardens on the following conditions:—

"'The Committee of the Exhibition are to undertake all the expenses of the Gardens until Thursday next inclusive. All money taken at the doors to be received by them. On Saturday, the 26th, the entrance to the Exhibition and Gardens to be at 2*s*. 6*d*., and Fellows and Debenture-holders to be admitted to the Exhibition on showing their tickets, in the same manner as on Wednesday last, the 23rd inst. The Committee of the International Horticultural Exhibition to be responsible for all damage done to the Gardens. In consideration of these concessions on the part of the Society, should there be any surplus in the takings of the Committee, the liberality of the Royal Horticultural Society will be duly acknowledged.'"

Col. SCOTT in continuation said, that a copy of that minute was sent to Sir Wentworth Dilke on the morning of the 25th of May, 1866, and the Exhibition opened for an extra week, commencing on the morning of the 28th. On the 7th of June, the following letter was received by the Assistant Secretary:—

"76, Sloane Street, S.W., 7th June, 1866.

"MY DEAR SIR,—When I asked for the copy of the decision of the Horticultural as to admitting the International visitors, I merely did so that we might have a record, and when you told me you had sent it here I thought it of so little importance, being aware, as I supposed, of the contents, that being busy I did not open it. At the end of the Show I was attacked with severe illness, and it was only last night that I read it. I regret this, because the last paragraph is one that I could not have permitted to remain one minute unanswered had I seen it at the time; I feel strongly that it ought never to have been entered. In conversation something was said about doing something for the Society, and I replied to the effect that the Council knew *my* view, as I had at the first meeting proposed that any surplus should be apportioned between the Gardeners' Benevoleot and the Horticultural, but that having been refused by the Society I knew not what the views of the International Committee might be, but that I personally had just had suggested to me what appeared a good idea to try and form a Lindley Library. This was all *my* talk; I had no power to bind the International Committee. The subject had not been attended to at the meeting with Mr. Saunders. I must ask that this letter be put on record.—Yours truly, (Signed) "C. WENTWORTH DILKE.

"Captain Cockerell, &c."

The subject, said Col. Scott, was brought before the Council on the 19th of June, and it having been discussed on the 25th, Mr. Wilson Saunders wrote the following letter:—

"Lloyds, 25th June, 1866.

"MY DEAR SIR,—I return to you Sir Wentworth Dilke's communication. The Council knows almost as much as I do of the matter, and the subject had better be brought forward next meeting, when I hope to be present. My own view of the case is, that Sir Wentworth Dilke on the part of the Committee acknowledged the principle that in case of any surplus accruing to the International Horticultural Exhibition the Royal Horticultural Society should have a claim therein. All this is in the minutes of the Council, and I think fully stated. I see nothing to blame on the part of the Council, and the whole matter rests with Sir Wentworth Dilke and his Committee, and no difficulty need arise. If they have a surplus, and will not meet the views expressed in the minutes of the Council, the matter must rest there.—I am, yours truly,

"W. WILSON SAUNDERS.

"Captain Cockerell, &c."

On the 31st January, 1867 (continued Col. Scott), a letter was written by Mr. Moore, Exhibition Secretary to the Committee of the International Horticultural Show, to which the following answer was sent, with a copy of the extract of the Council minutes, and a copy of the memorandum made by Mr. Wilson Saunders, both of which are alluded to in the letter. The letter itself was as follows:—

"Royal Horticultural Society, South Kensington, W.

"7th February, 1867.

"SIR,—In reference to your semi-official note of the 31st ult., concerning the intentions of the Committee of the International Horticultural Show, with respect to the disposal of the surplus of the International Exhibition, I have the honour to enclose a copy of the minutes of Council of the 24th May, 1866, to remind you of the terms on which the Council granted the use of the Society's Gardens to your Committee for another week. A copy of these minutes was at once sent to Sir Wentworth Dilke, the Chairman of the Committee, acting as their representative to negotiate the arrangement, and a memorandum of the result arrived at at the conference (a copy of which I enclose), was read to and approved by Sir Wentworth before he left the meeting. I have to request that you will lay this communication and enclosures before your Committee at the earliest opportunity.—I have the honour to be, &c.,

(Signed) "HENRY SCOTT, Secretary.

"Thomas Moore, Esq., &c., &c."

Having (continued Col. Scott), forwarded these, the next communication was as follows, from Sir Wentworth Dilke:—

"76, Sloane Street, 8th February, 1867.

"DEAR SIR,—Mr. Moore has placed in my hands certain papers relating to the Royal Horticultural Society and the International Horticultural Exhibition, and I must confess I am surprised to find that you have not included the letter I wrote immediately that I read the minutes, in which letter I distinctly stated that such minutes were incorrect. I have to request that a copy of my letter may be forwarded to be appended to the others.—I am your's truly, "C. WENTWORTH DILKE.

"Captain Cockerell, &c."

Col. Scott continuing. The following letter, enclosing that dated the 7th June, 1866, which has already been read to the meeting, was then forwarded, and on the same day a letter was also written to Sir Wentworth Dilke, which the meeting will hear read in its order:—

"Royal Horticultural Society, South Kensington, W.

"9th February, 1867.

"DEAR MR. MOORE,—I have received a note from Sir Wentworth Dilke requesting that a copy of his letter to Captain Cockerell, dated June 7th, 1866, concerning the arrangements between him and the Council for the use of the Society's Gardens by the Committee of the International Show, should be sent to you to be appended to the other correspondence on the subject. I accordingly enclose a copy of it, and have only to add that the omission of it when I sent to you the Council's minutes did not arise from any fear that the Society's position would be weakened by it.—I remain, your's very truly, (Signed) "HENRY SCOTT.

"Thomas Moore, Esq., &c."

The other letter was as follows:—

"Royal Horticultural Society, South Kensington, W.

"9th February, 1867.

"DEAR SIR,—I have forwarded a copy of your letter of 7th June to Mr. Moore as you request. I did not read it with the other documents, because I thought it possible that the evidence of the whole Council present as to what took place between you and them being opposed to your own impressions of it, you might be inclined to consider that the fault of

the misunderstanding lay with you, and act accordingly. Whether, however, you or they are in fault as respects the misunderstanding on the terms supposed to be agreed upon, there can be no doubt that the Committee should bear the responsibility of it, since you, their Chairman and Delegate, had in your possession a copy of the minute before they entered upon the occupation of the Gardens for the second week. I thought, therefore, that it was my duty as Secretary to send evidence of this to the Committee as soon as Mr. Moore conveyed to me semi-officially what their probable course would be. I have only to add that the omission of your letter from the correspondence was not caused by any desire to place the Society's position in a better light.—I remain, dear sir, your's faithfully, (Signed) "HENRY SCOTT.

"Sir C. Wentworth Dilke, Bart., &c."

That, said Col. Scott, completes the correspondence.

Mr. EDGAR BOWRING just wished to add one word of confirmation on that correspondence. He remembered having some conversation with Mr. W. Wilson Saunders on the matter, and amongst other things suggested was a royalty on each person entering the Gardens, but it was thought better not to interfere with the arrangements.

Mr. WILSON SAUNDERS wished to observe that his name having been brought forward, he would tell the meeting shortly what really took place, and why his name had been so brought forward in the transaction. A special meeting of the Council of the Horticultural Society was summoned to consider a proposal made by the Committee of the International Exhibition, and Sir Wentworth Dilke attended. The matter was brought before the Council, and Sir Wentworth Dilke said it would be desirable that, considering the large outlay and expenditure, the Exhibition should be kept open for some days longer. The Council considered that though they were not called upon to do so, yet there was every desire and every wish to serve the Committee, as they had incurred great expenditure, and it was thought very unadvisable to refuse to do anything which would be likely to cause an increase of the liabilities of the guarantors. Looking at it with that view, certain proposals were made, and it was thought that they (the Horticultural Society), would treat them (the International Committee), in a liberal way, and they said that if no profit was made then the loss should be borne by them; but if they did make any profit, then it was considered that the Horticultural Society should in fairness receive some portion of that profit. As the conversation went on he (Mr. Wilson Saunders) jotted down the gist of the argument which was carried on between the Council on the one side and Sir Wentworth Dilke on the other, as already read by the Secretary (Col. Scott), and the memorandum was in his (Mr. Wilson Saunders's), own handwriting as taken at the time. That there might be no mistake he would read it again:—"All charges paid. Saturday to be half-a-crown. Free entrance on Saturday to Fellows and transferable tickets. All money to be theirs, but in case of surplus a portion to be made over to the Horticultural Society." Those propositions were agreed to, and on that Sir Wentworth Dilke went to see his own Committee, and they (the Council) waited to meet their pleasure. After some very short delay the Council were either summoned or asked to go—at all events they did go to meet the Committee of the International Exhibition. It was a very hastily got together Committee—made under the arcade, and they were very anxious to have the matter settled at once, so that the bills might be got out and the advertisements issued. The Committee having heard the terms, agreed to them, and Sir Wentworth Dilke returned to the Council-room, and the minutes as they were drawn up were read out. That was exactly what took place as near as he (Mr. Wilson Saunders) could recollect. Yes, he was sure they were read out, and that was all that he knew about it. It was an agreement that they should meet the Council in that way, and the Council would meet them. The Council did so in a most straightforward, friendly, and liberal spirit, and the Council now expected the Committee of the International Horticultural Exhibition would look on the Royal Horticultural Society in the same way (hear).

Mr. HARRY CHESTER viewed the letter of Sir Wentworth Dilke as disclaiming his having any power to bind the body for which he was acting. He (Mr. Harry Chester) would have thought that Sir Wentworth Dilke had come to the Council from his Committee to bind them, and if they were not bound by his agreement, of course it never took effect; but clearly there was an agreement, by virtue of which the Exhibition was opened for a week longer than originally settled. He (Mr. Harry Chester) supposed Sir Wentworth Dilke merely meant to say that he could not bind the application of any particular portion, but he certainly did bind them as to some portion of the surplus. It certainly seemed to him (Mr. Harry Chester) that it would be better to refer the matter to some person—not necessarily a lawyer, but some person possessing a legal mind, and get him to state what ought to be done under the circumstances. That would bring the matter to a fair and reasonable issue; for while the Council of the Royal Horticultural Society did not want to press their claims unduly, or accept anything from the Committee of the International Horticultural Exhibition in the way of charity, still the Society ought not to give up anything to which they were entitled (hear, hear).

Mr. W. WILSON SAUNDERS would call the last speaker's attention to the fact that it was the correctness or the incorrectness of the minutes to which Sir Wentworth Dilke referred. He impugned the accuracy of them.

The subject then dropped.

Colonel CHALLONER could not but congratulate the Society on the great improvement which was visible in the financial statement, which, however, he could not help observing was still simply a cash account. What he wanted was a little more. He wanted a statement of the liabilities which the Society was now under, that the Fellows might know how much they were in debt. A statement was rendered in the account before the Meeting of the means of repaying what they had borrowed, but he (Colonel Challoner) would like to see a statement where the means of repayment were given on the one side, and the amount of the debt on the other. As an old member of the Society he was anxious on that point; and though he had found it was always difficult when he sat at the Council to obtain such a statement as he wanted, he (Colonel Challoner) would only say that experience did not seem in the least to lessen the difficulty. He would respectfully suggest that if His Grace the President would express a wish to the Council on the subject, the Fellows would soon be furnished with a more definite and clear statement of the real obligations of the Society than that afforded. There was one gentleman sitting near the noble President—he (Colonel Challoner) alluded to Mr. Wilson Saunders—and if that gentleman who was so useful and energetic in promoting the objects of the Society would also look to the subject it would all come right, and the desired information be rendered. He (Colonel Challoner) did not wish to be misunderstood in what he asked, for he would say, though he wanted more (a laugh), yet the cash account was very clear and better than what they had hitherto had.

Mr. JAMES WHEELE desired to suggest that there should be some alteration in the rules with regard to the Gardens at Chiswick, so that the Fellows if they asked for anything, surely ought to have something given to them; not, of course, the best cuttings, but something.

The PRESIDENT did not think there would be the slightest difficulty in any Fellow having either buds or cuttings if they wanted them, except, of course, under exceptional circumstances. It was quite allowable for them to be given.

Mr. WHEELE would merely say that when his gardener went there to ask for a few cuttings, he was told by the man he spoke to that it was as much as his place was worth to give him anything.

Mr. WILSON SAUNDERS submitted that perhaps the man had not any authority with him as to who he was.

Mr. WHEELE assured the worthy Member of the Council that the man who gave the answer was told who it was.

Mr. WILSON SAUNDERS assured the last speaker that it was invariably done—at least, such were the orders.

Colonel BURLETON thought it right to mention that he went there and was told he could not have any cuttings, but if he chose to buy any fruit or Grapes he might do that; but as to any cuttings being given him, that was not in the province of the gardener to whom the request was made.

Mr. WILSON SAUNDERS wished to know who his friend asked for the cuttings.

Colonel BURLETON did not know the man's name.

Mr. WILSON SAUNDERS could only say that the last speaker should have gone to the right person, Mr. Barron.

The PRESIDENT said that, as he understood the matter, any application must be made to Mr. Barron, the head gardener, and none of the under gardeners had any power or authority to give anything away. His Grace felt quite sure that the members of the Society would see how important it was that the sole power of giving away buds or cuttings to the Fellows should be vested in one responsible person; but if there was any difficulty about it the Council would see into the matter and put it on the proper footing. Several important points had been raised and discussed, and now, it having been moved that the Report be received, would some gentleman second that proposition?

Colonel CHALLONER had much pleasure in seconding the motion that the Report be received and adopted.

The PRESIDENT put the question, which was carried unanimously.

Major R. TREVOR CLARKE wished to say a few words as to the Lindley Library, which he feared was likely to slip away on account of lack of funds—that the Society could not afford to buy it. There was no doubt that it was very valuable, not only from its own intrinsic merit, but from old associations and other causes. The Fellows would remember it was not the first time the Society had been in possession of a fine library, and he (Major Clarke) would not say that they were ignominiously sold, because the sale was from a good motive, but he would say, for he knew it, that it went to the hearts of all the members of the old Society. They had now a second chance, a chance of obtaining a most valuable library which would be endeared to them all by old associations; and he heard with pain and grief that it was proposed to sell it again, and that the Royal Horticultural Society could not afford to buy. Now, if they were poor they were honest, and as they were many so he was hopeful, and had a strong belief, that there was a stern determination now to recover the fortunes of the Society by energetic and well-directed economy; but he (Major Clarke) would not believe they were so poor as not to be able to get that valuable library. They might be hard up (a laugh), but not so hard up as that came to; and for one having the interests of the Society deeply at heart, he said, not only let them keep it, but build a place for it, so that they might look up to it as "household gods." The excellent Secretary of the Society had got them down "there," locked up in a place which might be a kind of stable; and having them under lock and key, he (Major Clarke) hoped he would keep them there (hear). He would propose, or rather he would suggest, that the

Lindley Library be not sold, but that the Royal Horticultural Society become the guarantors, and surely they might arrange to pay for it by the end of next year if they could not do so now. For his own part he should be glad to give a £10 note, and surely there would be many who would come forward and preserve so very valuable a possession for the Society (hear, hear).

The PRESIDENT observed that the real question was whether the Society was in a pecuniary state to enable them to keep the Library. Had they in the present condition of the funds power to lay out £600? If they were able to do so every one must feel it was very desirable it should be preserved for the Society. The Council would be most willing as well as himself (the President) in doing anything that should be deemed advisable to assist in the important object suggested (hear).

The Scrutineers, Messrs. Fortune and Booth, then delivered in the ballot papers, and it appeared that Lieut.-General the Hon. C. Grey, Major Trevor Clarke, and Mr. Wentworth W. Buller were unanimously elected to fill the ordinary vacancies in the Council in the room of the vacating members, Mr. W. Wilson Saunders, F.R.S., Sir Arthur Buller, and the Right Hon. W. Cowper, M.P.

The officers elected were as follows:—President, His Grace the Duke of Buccleuch; Treasurer, Mr. Geo. F. Wilson, F.R.S.; Secretary, Lieut-Col. Scott, R.E.: Expenses Committee-men, Mr. Geo. F. Wilson, F.R.S., Lieut.-Col. Scott, R.E., Mr. Henry Cole, C.B.; Auditors, Mr. James Nicholson, Mr. John Gibson, Mr. Robert Hudson.

The PRESIDENT declared the elections carried, and that concluded the business of the Meeting.

Col. CHALLONER proposed a cordial vote of thanks to the Duke of Buccleuch for his courteous and obliging conduct in the chair, which proposition was seconded by Mr. Harry Chester.

His Grace expressed his thanks for the compliment, and the Meeting terminated.

LUTON HORTICULTURAL SHOW—TIREBUCK'S PELARGONIUMS.

DURING last season there were two very good horticultural and floral exhibitions in the town of Luton, of which, but for the press of other matter, I had intended to take some notice. I would then have alluded to some of the drawbacks, and to some of the causes which operate as hindrances to success in the case of provincial exhibitions, and I may yet do so before exhibition times come round. There was nothing wanting at Luton to command success but at least a tenfold greater attendance of visitors, and considering that Luton is pre-eminently distinguished alike for the number, the beauty, and the industry of its female population, it was a matter of regret that many more of them did not attend to show that "beauty" could admire the beautiful. In all such cases in manufacturing towns, and especially until such exhibitions were thoroughly established, it would be wise policy, instead of having tents in an open meadow, to have the show in the largest room that could be obtained, and to have the room open until between nine and ten o'clock in the evening. If in such a case those who could not well leave their duties during the day did not attend, it would then be proof positive that in that particular place there was no taste for such things, and that even the love of the beautiful, which some contend is innate, especially in female character, would require to be formed before it could be fostered.

I shall not at present say anything of the excellent productions contributed by the manufacturers, merchants, tradesmen, gardeners, and cottagers of the town and neighbourhood, but would add that the exhibition was much indebted to Messrs. Lane for a fine collection of Roses; to Mr. Spriggins, nurseryman, of St. Albans, for a similar collection; to Mr. Watson, of St. Albans, for another, also for beautiful Ferns, and a well-grown collection of the best tricolor Pelargoniums, including fine plants of the beautiful Miss Watson; and to Mr. Tirebuck, nurseryman, Luton, for a large miscellaneous collection of plants, including a number of seedling Variegated and Zonale Pelargoniums, which arrested a good share of attention, on account of their merit. After seeing a goodly number of seedlings during the season, I picked out a few from those exhibited, and examined them again in the houses and grounds at the nursery, and though my opinion might not be the same as that of others, or even in unison with that of Mr. Tirebuck, the varieties selected are what I would like to have the chance of cultivating myself.

1. PELARGONIUMS WITH FINE FOLIAGE.

Kate Tirebuck.—This is chiefly distinguished from Mrs. Pollock by the zones of yellow and purple being broader, brighter, and more conspicuous.

Patriot.—Chiefly distinguished from Mrs. Pollock by its growth being more free and vigorous—a matter of importance in some places.

Dandy.—A pretty little variety, in the way of Italia Unita, but far more vigorous in its habit.

The following two would make brown-tinted beds. I forget what the flowers are like.

Richard Kelly.—The centre and edges of the leaves greenish yellow, with a broad brown zone between them.

Catharine.—Greenish yellow edging, narrow plain green centre, and deep brown zone between. These two will not compare with the Mrs. Pollock and Italia Unita sections, but they are distinct, and from their free growth would flourish where the others might be miffy and sickly.

Lady Slade.—I mention this, because with scarcely a tinge of green on a leaf or two, all the other leaves were of a pure white, and had maintained the same character for more than a twelvemonth. I have met with a few seedlings, and plenty of sports of this white colour in the leaves, but I never knew them continue in health, or even in existence for any length of time. I should even be doubtful of her ladyship keeping her white robes unsullied; but time will tell.

2. NOSEGAY PELARGONIUMS.

Felix.—This, as noticed by myself, is a beautiful kind for a low bed. The neat green foliage carpets the ground, the flower-stalks rise thickly 6 or more inches above them, the trusses are large, the individual flowers small, and flickering with every breeze, and the colour a lilac pink. A little gem.

Oliver Twist.—Very bright red flowers, large trusses, good habit.

Masterpiece.—Bright orange scarlet flowers, deep green foliage, dwarf compact habit; free bloomer.

Stella Improved.—Bright scarlet; free blooming.

Cerise.—Scarlet Nosegay; huge trusses; compact habit.

Jewess.—Indian Yellow scarlet; large truss of blooms; foliage deep green, with a black zone.

3. PELARGONIUMS WITH REGULAR-FORMED FLOWERS.

Emily Moreland.—Bright scarlet flower, with a white eye; dark zoned foliage; free blooming, medium as to vigour of growth. A very nice variety.

St. Clair.—Pink salmon or cerise scarlet blossom; individual flowers very large; trusses large.

Luton Gem.—Deep scarlet, shaded with a light stripe, large truss.

James Nixon.—Crimson scarlet, large flower, large truss, free-blooming, dark zonate foliage.

Crimson Cushion.—The crimson is striped with white, and the habit of growth compact.

Tirebuck's Gem.—Rosy blush colour, free blooming, good habit.

Out of some scores of good flowers I have selected six in each division, and were they for my own growth, and I could only take a few, I would choose those first named, preferring the first to the second, the second to the third, and so on. No doubt Mr. Tirebuck will send out a larger list when the plants are purchasable. I will merely mention one more.

Pearl.—Pure white flower. An improvement on Madame Vaucher, so far as I could judge, the white colour remaining white, and not becoming pinky, as in Madame Vaucher, but I did not see it out of doors. The trusses were large, and the habit of the plant dwarf and compact.—R. F.

LET COMPETITORS BE FAIRLY MATCHED.

I HAVE a small garden and greenhouse, and in addition to turning out two or three thousand bedding plants annually, I grow a few specimens of Zonale Pelargoniums, Fuchsias, Chrysanthemums, and other plants. I have no gardener or assistance of any kind, and raise and plant everything with my own hands.

Having been rather successful last year with my specimen plants I thought I would exhibit at some of the neighbouring shows. I sent for some prize lists, and entered the plants in the classes open to amateurs and gentlemen's gardeners, the other classes being for nurserymen and cottagers only. I need hardly say I did not obtain a prize, and no wonder, for I was the only amateur exhibitor, and had to contend against the gardeners of noblemen and county gentlemen employing half a score of gardeners or more, with better appliances and more glass than most of our best nurserymen, and actually taking prizes over the nurserymen's heads at the same shows.

I looked carefully through the schedules of at least a dozen horticultural societies, and in every case the amateur was coupled with the gentleman's gardener. Now, I see no objection to an amateur competing with gentlemen employing not more than one gardener, and that restriction should be made in a few classes to give the *bonâ fide* amateur a chance. As it is he has none. If you can find space in your Journal for this protest against such an anomalous state of things I shall be obliged, and I trust it may be the means of opening the eyes of the committees of horticultural societies to the wants of the genuine amateur.—Calcaria.

IMPROVEMENT OF COTTON PROMOTED BY A KNOWLEDGE OF THE PLANT.

To ensure successful cultivation in pots under glass, I have noted certain points of treatment as essential. These will be embodied in the following remarks.

Specially Suitable Soils.—Without trenching upon botanical debatable ground, the great Gossypian family may be divided into two geographical races—the Asiatic and American—the first comprehending the Surats or native Cottons of India and perhaps Africa, and the second represented by the large-habited, robust denizens of the Western world.

These two races seem to require two distinct kinds of soil; light and moderately manured soil for the American, and peat for the Indian sorts. Strong loamy soil or an excess of manure will render the American Cottons perfectly unmanageable, inducing an unproductive luxuriance, and a tendency to drop the flower-buds and young bolls. On the other hand, Gossypium indicum and its varieties are much more delicate as pot plants, and will not thrive in loamy soil. Pure peat and sand must be used for them while in a young state, the material being strengthened by a sparing addition of loam and manure as the plants advance towards maturity. Skilful gardeners may be able to use other means; I only give the safe side of the question. The Americans do not require peat in any stage. Very careful draining is essential for every kind of Cotton. Manure water may be used with advantage to full-grown fruiting and flowering plants, and the agency of special manures, as, for instance, nitrogenous, phosphated, and saline, might be profitably studied. These might be added with the final shift, or applied in a liquid state at regular intervals.

Temperature.—The Cotton is a warm stove plant, and will not succeed really well unless treated as such. It may, however, be grown in a vinery at work, if not overshaded, during the hottest month of the year. The Indian plant, although grown to profit in Europe, is the tenderer race, and will require the warmest berth and the greatest share of attention.

Sowing and Rearing.—The first half of the present month of February may be considered on the whole the best time to sow. January sowing has its advantages, as tending to make the most of our short English summer, but the management is difficult to amateurs. Any good gardener, however, who has been used to grow winter Cucumbers, would find no difficulty; indeed, I sow all the year round in the prosecution of experiment.

Where accuracy of observation is desired, and little in the present state of confusion of sorts can be gained without it, the greatest care should be taken to ensure the identity of all seeds sown. It will be well to sow each seed separately in a small pot, labelling it at once, and repeating also the name or description in pencil on the side of the pot. No care or discipline that I know of will prevent gardening men or boys from losing or confusing labels. I am in the habit myself of causing all my seeds to germinate before sowing, by placing them under conditions of great warmth and moisture, in various ways well known to good gardeners.

The great condition of success now depends upon the encouragement of rapid growth by a quick succession of shifts, never allowing a moment's check, by over-development or matting of the roots, till the plant is established in its fruiting pot. The size of this will be regulated of course by the house room available. What is called a 24-sized pot will be large enough to afford five or six good pods of the New Orleans and Sea Island breed, and will grow comparatively large specimens of the Indian native sorts, which will thrive and fruit in much smaller masses of soil.

After-cultivation.—The plant at all times requires large quantities of water. Any irregularity in this respect will tend to produce the vexatious droppings of the bud, so ruinous even in the real Cotton fields of the planters. In watering the plants never leave off pouring till the water passes through and comes out at the bottom. In hot weather this will be required several times a-day. The sides of the pots should never be exposed to the full sunshine; this will often destroy the rootlets in contact in a few minutes, and so check the plant more or less. After such a check, growth will recommence, but at the expense of the previously formed buds, which are thrown off by the effort. When plants in bud or flower require to be shifted into larger pots, they should be afterwards placed in the most favourable situation for shade and moisture for the same reason.

Injury by Insects.—The plant is subject to red spider, and is very sensitive to the attacks of the common green aphis. These must be combated vigorously, but the difficulty in this respect is no more than may be readily surmounted by an industrious and clean gardener.

Period of Ripening, &c.—The early-ripening sorts, usually grown as annuals—that is, the different kinds of New Orleans, Sea Island, and Egyptian, with the majority of the Surat tribe, begin to ripen their pods in succession, from the end of July to the close of the year, flower and ripe fruit being often seen on the same plant. Late plants will continue to ripen through the winter in a warm, well-managed house. The bolls may be gathered as soon as they split open. The valves will then soon curl outwards from the loss of moisture, and the masses of seed and fibre being relieved from their pressure will swell out and show the beauty and quality of the staple. Pretty museum specimens may be made by cutting off the boll with a small branch attached to it, and then pressing the leaves between plain surfaces, the pod itself being left free. Never omit labelling each specimen.

Summary.—The general requisites may be summed up as follows:—

A moist, warm, and even temperature, with abundance of water.

Quick cultivation.

Avoidance of strong or highly manured soil.

Avoidance of any sudden check to growth.

The use of two distinct descriptions of compost, and

The use of light soil as a general rule.—R. Trevor Clarke

Welton Park, Daventry.—(Cotton Supply Reporter.)

A GOSSIP ABOUT POTATOES.

(Concluded from page 100.)

According to the orthography of my native county of Suffolk, and the gentleman in "Barbox Brothers," "I larff, I dew," when your famous Rose correspondents, after they have indulged themselves with swinging gallops upon their Potato hobbies, come to recommend a quiet jog-trot with three or four kinds. Do you not think they would broadly smile if I were to study Roses for years, write long and lovingly about them, and then end with a trite moral—"But after all, Gloire de Dijon, and Climbing Devoniensis, for walls; Duc de Rohan, and Souvenir de Malmaison, with the old Cabbage, old Moss, and China Roses, thrown in for the open borders, are all that any one can in reality require in that way"?

Well, one of our best judges and cultivators of the Potato who lives near Dorking, and who exhibited store Potatoes next to mine at the Great Show last May, is also going to send me sorts that I have not in my category, but which have gained his good opinion. Also, my friend, Mr. Wm. Cruickshanks, of Langleybury, promises to send me "Transell's Seedling," a sort he thinks highly of. I have long desired to try it. Mr. Cruickshanks formerly sent me the Pebble White, an excellent sort of the Lapstone family, and rather later than the original, though equal to it, and it will keep longer.

Practice proves to me that there are many kinds of excellent Potatoes which can be produced good in almost any soil, whilst there are many other equally excellent kinds that require one particular kind of soil to bring out their qualities. It appears to me we are but just stepping on to the threshold of this knowledge, and the more we search into it the more we shall have to acknowledge we have very much to learn.

Out of at least one hundred varieties of Potatoes under experiment during a period of thirty years, I can, in the spirit of the paragraph above, recommend the kinds which I exhibited at the Royal Horticultural Society's Gardens, South Kensington, last November. They are described in a report styled "Home Growths," at page 386, No. 295, first taking the precaution to

strike out of that list the sorts which are newest to me, or upon which I have not sufficiently experimented—namely, Webb's Telegraph, Premier, Royal Ash-leaf, Early Emperor, Fenn's Onwards, Russet Kidney, Beehive, and Wheeler's Milky White. The last I prophesy will become one of the most generally-grown sorts. I had a fine dish of it at the show, but it and the Lapstone were accidentally left out in the report.

The following sorts I should say can be grown good upon every description of soil unless the land is very stiff or wet, and even then the cultivation of the kinds can be carried out with success on the ridge-and-trench plan, such as I adopt in this garden, and have frequently stated. An account of it will be found at page 351, No. 163, Vol. VI., and it is advised for field culture, in Vol. IV., page 148, No. 100. I would respectfully refer Mr. James Dobbie and Mr. D. Thomson to those papers, where they will see how very slightly I differ from them in their good practice, which they have lately described in these pages. I do not feel quite so sure as Mr. Thomson, however, whether the ridge system would not be found to answer, if the sets were planted 8 inches deep in February, so as to allow their roots to take an early hold of the soil in the ridges, even should it be of a light, sandy nature. The tubers would certainly have a greater depth and bulk of soil to grow in, and I find these ridges of earth maintain moisture to a great extent in long-continued very dry weather. Besides, a double surface of soil is gained for the beneficial influence of atmospheric action, always so congenial to the well-doing of Potatoes during their growth. I never, however, tried or recommended this ridge system for light, sandy soils, nor have I the chance to try it in this neighbourhood, where the land varies in character from clay to loam, and from stonebrash to gravelbrash. The cottagers' allotments here are chiefly situated upon the latter description of soils, and there I prove the effects of change of staple upon the sorts, and so procure my seed from ground of a texture as opposite as possible to that of our garden. I was thus soon enabled to find out that all coarse-topping Potatoes are more suitable for cottagers on poor land, or for field cultivation, than the meagre finer-foliaged sorts. Starvation of the root is made up for in a great measure by the multiplication of mouths in the leaves feasting on the carbonic acid in the air. The smaller the top the richer should be the soil, and *vice versâ*; I find most of the coarse-foliaged Potatoes that I have introduced maintain themselves amongst the allotment-holders, but the finer sorts soon become lost with them.

I will now confine myself to my doings in this garden. The first quarter of April had passed away before I planted the varieties above mentioned, and the following:—For frame or early garden culture, Shutford Seedling, Early Ten-week, Hogg's Coldstream Early, White-blossom Ashleaf, and Mitchell's Early Albion Kidney; for the garden, or upon good hearty soil, two or three early sorts, Daintree's Seedling (round), Daintree's Seedling (kidney), Haigh's Kidney, Fortyfold, Pebble White, and Lapstone; for the farm, or upon rather poor and light soil, Sutton's Finest Regent, Cheshire Pink-eye, York Regent, Walker's Scotch Regent, Freebearer, Prolific, Negro, White Farmer, Fluke, Gryffe Castle Seedling, and British Queen (kidney).

The haulm of the first early sorts began to turn yellow about equally, excepting Webb's Telegraph; this variety lagged sadly behind—so much so, that upon the exhibition table I placed it among the second early kinds. Coldstream Early here again was first for economical household use, Shutford Seedling and Mitchell's running it very closely; so, also, did the Ten-week and Premier, but I durst not encroach upon their limited quantities.

Amongst the second earlies the foliage of Royal Ashleaf and Daintree's Seedling (round), first began to turn yellow; then that of Pebble White and Wheeler's Milky White—indeed, so long was the latter with me before its dwarfish, handsome, dark pea-green foliage began to take the yellow tinge, that I questioned whether I ought to call it a second early

For the later sorts Early Emperor was first yellow in the foliage, closely followed by Walker's Regent and Gryffe Castle Seedling, neck and neck; the rest were nowhere, at least in regard to the ripening of the leaves, for at the beginning of September the disease began to strike the foliage with blackness. On the 10th of August my friend, Mr. J. Gardner, who stated the history of Premier Potato at page 483, No. 300, wrote to me stating it would afford him great pleasure to come and see my Potatoes. I answered, "Come quickly, as I have lately observed some spots on the leaves, and I seem to scent the disease in the air; should it increase, it would set me to haymaking the haulm, and then a most interesting feature to the amateur would be lost, as no judgment could be formed of the differences in the foliage of varieties in their natural habits of growth." My friend took me at my word, and I believe we both found the day of his visit by far too short. I have often been led to think since reading in No. 282, page 147, about the Dunoon gentleman, "who preferred the useful to the ornamental, and had turned his front garden into one vast Potato-bed!"—that my friend must have carried away with him from here some such an impression of me as that expressed by "G."

The unfortunate year 1866 will certainly be marked with black letters by the majority of Potato-growers, in this vicinity especially. Some of my neighbours lost almost their entire crops; with me the leaves of the Early Emperor were the first to become spotted, on the 8th of August, and by the beginning of September the foliage of the whole Potato tribe had succumbed. The electric state of the atmosphere, with the prevailing rains, kept me haymaking at the haulm when the sun shone for a few hours consecutively. I explained the nature of this proceeding in 1865, in No. 246, and I again derived great benefit from the operation last year. Anticipating much trampling in the trenches between the ridges, I did not plant any of the Cabbage tribe in the trenches; and, contrary to my custom, I determined experimentally to leave all the Potatoes in their ridges, allow the disease to do its worst upon them, and so find out the sorts most capable of resisting it.

From the 22nd to the 27th of September the "lifting" took place, and I had to reckon my loss from the disease altogether at nearly one-third, which I could afford to spare, as I never remember a finer crop. Judging the early and late kinds together, I computed them at quite 16 tons per acre, and they are finer for flavour than I ever knew them off this soil. This serves to confirm the soundness of Mr. Radclyffe's advice about leaving in the ground Potatoes intended for culinary purposes till they are quite ripe; and, as Mr. Thomson expressed it about his "Ross's Potato," my Gryffe Castle Seedling, when being taken up, literally covered the ground. Let an extract from a letter one of the Editors wrote me vouch for the rest:—"What a very interesting collection was yours in the South Kensington Conservatory last week! I never saw so large a collection of well-grown, perfect, and useful-sized Potatoes." Old Betty—I beg pardon—the Early Ten-week, did not produce a diseased tuber, though more of the Premier succumbed than I liked to spare. The crop of Webb's Telegraph was nearly all diseased, I but just managed to save a dish of it fit to show. The murrain as it struck the other early kinds was nothing to cause me regret.

Of the second early kinds Royal Ashleaf stood best, and with a fine yield; of Beehive three-fourths of the crop were rotten. The third worst in this list was Wheeler's Milky White, of which I lost quite one-half; but a Fluke-looking seedling of mine, which I thought much of, gave way altogether. Of the Onwards, the female servants said they counted about one in seven bad, as they cleaned them for cooking; say one-third in quantity for the rest. Of the field sorts, Cheshire Pink-eye was quite free of disease, and Gryffe Castle Seedling nearly exempt from it; but of the Early Emperor I only just saved the plate of shabby tubers I exhibited at South Kensington. The Negro, also, was dreadfully cut up, and, in fact, all the coloured kinds were, or afterwards became, much more diseased than the whites. I am happy to say, however, that the seed Potatoes which I greened upon the ground have kept well, which, according to your correspondents, seems to be an unusual circumstance.

I think I have now done and said, all that I could, or can do usefully towards helping to assist others, by unfolding my last season's Potato enterprise. I trust I shall not be likened to the rat, preaching from his pulpit of cheese, when I say that we partake of the produce both boiled and baked daily, and we are well provided with store Potatoes till young ones come again.

Your subscribers in this neighbourhood have been into the store cellar to view my crop, and especially the member for this borough, who seemed to admire them for size and quantity, given the space of the ground. I show visitors the ridges and trenches, how the ground is well drained, the earth closets, and the house-sewage tanks; and, as Beau Brummel exclaimed formerly of starch, I explain the earth closets form "the man!" Still, as our medical doctor said to me the other day, when he came to request a view of our hygeian system of earth closets,

&c., "Manure will never bring satisfactory produce without a quantum of science, and the combination of practical knowledge how to apply it."

I will conclude this paper in agreement with your (and I feel proud to add my), excellent correspondent "SOLANUM," at page 6. When "science and practice are alike baffled we must bow to that which no man can comprehend, the will of the great Ruler of All." In the meantime, I will add, let us fulfil to the best of our power, that extra degree of exertion which Providence for wise purposes has entailed upon us.—UPWARDS AND ONWARDS.

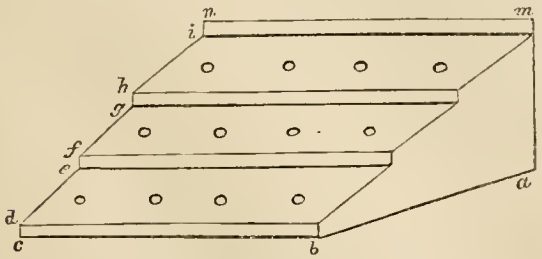
NOTES OF AND ABOUT ROSES.

(*Continued from page* 84.)

THE rules to be observed by exhibitors, and for the guidance of judges, should be strictly adhered to. Some of the rules laid down never have been conformed to; the size and forms of the boxes or stands are noticeable instances of this. A glance along the exhibition-table reveals some curious discrepancies in this respect, reminding one of the older streets of London, where the proprietor of each house built according to the design his fancy or convenience suggested. Eighteen inches is the usually required width of a stand, the height in front 4 inches, and at back 6 inches; but stands of different dimensions from these are placed on the table, and propped up behind to any height. These stands are also directed to be painted green, and surfaced with green moss; but the wear and tear, chiefly arising from conveyance over long distances to and from the places of exhibition, and the scratching and rubbing to which they are always liable, make them look anything but green, or any other colour that is respectable. As for the moss, it has as frequently the appearance of a door mat picked to pieces, as of the verdant colour intended.

We should not quibble about trifles. I will assume that the boxes were made prior to the rule, and the owners not unreasonably refused to alter or to have new stands made in compliance. Green moss cannot be obtained everywhere, and the managers of the exhibitions have yielded to the logic of facts.

In the course of time unjustifiable divergencies have crept in. If one party complies with a rule laid down for judges and exhibitors, and another diverges from it, be the divergence ever so trifling, the conforming party is not to be blamed for noticing it. For instance, if the rule states, as it does in the Crystal Palace schedule, that the truss must be shown with its bud and leaves as cut from the tree, *any addition, even of a leaf, will disqualify*, the last clause being in italics, is it a violation of the rule if, supposing no leaf or anything pertaining to a Rose be added, the flower is tied neatly to a stick to keep it in place, or to give a uniformity of appearance to the collection in the box? Different kinds have different habits. Senateur Vaisse, Pierre Notting, and some others of our best Roses do not hold themselves up so erect as the stately Comtesse de Chabrillant and Duchesse d'Orleans, and most Tea Roses are a little pendulous under these circumstances. Is an exhibitor justified in giving the aid of a pair of crutches to put them in an unnatural position, in order to make them stand out stiff and erect like others that have that habit naturally? It would be well if the rule were made distinct on this point. I refrain from further remarks on this subject, for it is not pleasant to be detecting others' faults.



a b, Width 18 inches. *b c*, length 24 inches. *a m*, height 12 inches. *c d*, height in front 3 inches. *e f*, *g h*, each 3 inches, the height between each ledge or flat. *i n*, 3 inches, forming a back to the upper ledge. *d e*, *f g*, *h i*, each 6 inches, minus the thickness of *e f*, *g h*, the width of the ledges.

I never did like the boxes or stands at present in use; the long line of these unsightly objects on the exhibition-table excites a feeling that ill-usage is designed to the Queen of Flowers by the shutting-up and then exposing her in a clumsy expedient unworthy of her. Something might be done to improve this state of things. I have not the good fortune to possess any inventive faculty, but by way of a practical hint I have ventured to give a rough outline of a stand for twelve, which is free from some of the objections attending the stands at present in use.

As the sketch indicates, the stand consists of three flats or ledges, each pierced with four holes for the insertion not of zinc tubes, but of glass phials, which are to rest on a strip of wood beneath the holes, so that the rim of each phial may project at least 1 inch above the ledge; this will allow the stem and foliage of each flower to be seen clearly and to advantage. No moss should be allowed, and the judges as well as the spectators will see the truss or flower as cut from the tree in its integrity. There is nothing better for setting off a Rose than its own foliage, which varies in different kinds, and in many of them is of itself beautiful. Some method of exhibiting like the above will bring out this point far more clearly than the boxes at present in use. For convenience in carrying flowers to exhibitions, the stand may be fitted into a box or case of rough boards, or otherwise, that while holding the flowers as safely as the ordinary box, it can be taken out of its case to be placed on the exhibition-table without being disfigured or scratched during conveyance. Nor will the stand, together with the case containing it, occupy much more space, or be much more expensive in construction, than those now in use. On the exhibition-table this kind of stand will afford the judges and visitors a more distinct view of the flowers placed in it, and when the attendance is expected to be large, there will be an advantage rather than otherwise, in not placing the stands too closely together.

In showing a large number of cut flowers in single specimens there must be a kind of monotony in the general appearance of the exhibition, and the suggestion now offered would not tend to diminish it. Will correspondents kindly give their views on the subject, and improve upon the hints now thrown out?—ADOLPHUS H. KENT.

THE INTENSE COLD AND ITS CONSEQUENCES.

STORNOWAY, SCOTLAND.—You may like to hear how we have fared in our latitude of 58° N. during the severe snowstorm of last month. The snow and frost were quite unprecedented. The readings of the minimum thermometer, protected in the shade, and 4 feet above the ground, on the coldest nights were —January 2nd, 23°: 5th, 18°; 6th, 20°; 7th, 30°; 12th, 19°; 13th, 21°; the rest of the month they varied from 25° to 43°.

Thanks to the influence of the gulf stream, the injury to plants and shrubs is not so great as one would have expected. Some plants of Rhododendron ponticum, Laurels, Portugal Laurels, and Escallonias in exposed places have the last-made shoots much browned. Gaultheria shallon and Garrya elliptica in a high exposed place have not been touched. Single Red Camellias were much browned, also some Golden Holly. Berberis intermedia and Darwinii have not been touched, also Ribes speciosum. Common Fuchsias in the shrubbery and plantations are unhurt, except at the points of the shoots. Roses have not been much affected. Some of the Cabbages and Broccolis have been injured; also Globe Artichokes. Catkins of Hazel, Alder, Cut-leaved Alder, and Black Willow, though very forward in December, do not seem to be at all affected. The Hybrid Rhododendrons are not injured, and seem to be less tender than R. ponticum, owing, no doubt, to the latter making a third growth late in November and December. Crocuses, Snowdrops, and mixed Tulips are making rapid growth. Ribes sanguineum is very forward in bud; Primroses, Hepatica, and Polyanthus are in flower.—JAMES MATHESON.

WELTON, NEAR DAVENTRY.—We have escaped almost unscathed by the frost at Welton. The only evergreen touched here has been Cratægus crenulata on a south wall; even this is only browned. All Broccoli, however, is killed.—R. T. CLARKE, *Welton Place*.

BANFFSHIRE.—This place is seven miles inland from the town of Banff, and is in 57° 35′ N. latitude. The situation is damp, being only about 6 feet above the level of the river Deveron. I can scarcely tell yet to what extent Roses and evergreens are damaged, as we had about 26 inches of snow on the ground when we had the most severe frost in January. On the 5th the lowest temperature was 2°, and on the 21st and 22nd 1° below zero.—J. C.

Monmouth.—January 19th and 20th, 4° at 7 A.M. The vegetables here have suffered much; Broccoli has all been killed; Cabbage plants, Leeks, and Spinach are all dead down to the snow line. Rose trees appear to be all killed, excepting a few hardy sorts. Shrubs have not been in the least injured. —H. Comley, *The Gardens, Hendre.*

Keswick, Cumberland.—I live in one of the cosiest nooks in England, just at the foot of the giant Skiddaw, and surrounded by his brethren of greater and less stature, truly a numerous family. The frosts found their way even here over the tops of the hills, and 25° below freezing was the minimum temperature registered. It has done us somewhat extensive damage; not a Broccoli is left of one of the finest squares I have seen this season. Rhododendrons have suffered much, in common with Portugal and common Laurels, whilst the Laurustinuses are entirely gone to the snow line. Roses seem to have stood well, but how it may go with the flowering, time alone can decide.—J. V.

Upper East Sheen, Surrey. — To confine myself as much as possible to Roses: they are more extensively killed and wounded than ever came under my notice. Hybrid Perpetuals Monte Christo, Mrs. Charles Wood, Cardinal Patrizzi, are more or less seriously hurt. Bourbons Pierre de St. Cyr, Julie de Fontenelle, and Empress Eugénie, are destroyed. Noisette Fellenberg is dead, Du Luxembourg much injured, Lamarque nearly dead, Isabella Gray dead, Rivers's Augusta dead, Jean d'Arc dead, Triomphe de Rennes dead. Bourbon Souvenir de la Malmaison is hurt. Tea China Louise de Savoie, Madame Willermoz, Madame Falcot, and Niphetos are dead, Vicomtesse de Cazes injured only, Madame Damaizin dead. China, Common a good deal hurt, Mrs. Bosanquet dead. Amongst old favourites uninjured are Narcisse, Ophirie, Auguste Vacher, and Noisette La Biche; all without protection. Of evergreens, Sweet Bays, Gold and Silver Hollies, Deodars, Laurustinus, and Pinus insignis are all a good deal punished, but less severely so than on the lower level. Other Conifers and shrubs are uninjured. The lowest temperature was during the night of January 4th, when it was 3° below zero.—Charles Ellis.

MR. ROBERT DICK.

Scotland has lost a son of whom she may be justly proud, and science has to mourn one of her most devoted students; and yet we have only to chronicle the death of a poor baker of Thurso, who was considered mad by some, who died in penury, and was not followed to the grave by a single relative. Mr. Robert Dick, who was better known in scientific circles in London than among his own townsmen, has passed away. He was, perhaps, the most enthusiastic amateur in botany, entomology, and geology of our own time. Hugh Miller gained many a lesson from him, and even Sir Roderick Murchison was proud to admit that he had gleaned information from the baker of Thurso. His devotion to his scientific pursuits was so great that he neglected his business, and the inevitable result ensued. Shall I then hold him up as a pattern to our younger readers? Most assuredly. While studying the virtues of a man, we may also learn to avoid his mistakes. No one with any common sense would take up the study of science with the idea of making a fortune by it. As I have said more than once, the love of science must, like virtue, be its own reward. There are many things which cannot be computed on the £ *s. d.* scale—health, for instance, or happiness. Do you for a moment suppose that in his latest hours Mr. Dick wished that his life had been passed without the slightest acquaintance with the plants, insects, and fossils he had spent so many days and nights in studying? No; I firmly believe that he had more pleasure in the span of life allowed him than any millionaire. I know many scientific men whose income is £500 or £600 a-year at least, who are as poor as he was. If their income were doubled to-morrow, they would spend every farthing in the pursuit of their favourite science. Two of the leading men in their several branches, who have died within the last few years, have left their widows so poor that they were obliged to seek a means of living for themselves.

I did not know Mr. Dick personally—there were not many men who did; but from what I have heard of him, I should think he was somewhat eccentric, and decidedly reserved and uncommunicative in his manners. Many such men there are, unfortunately; they find few capable of conversing with them on their favourite subjects, and so by degrees learn to shun society, and keep their knowledge stored up in its perishable casket. This is a great and fatal mistake. A man ought to enjoy the keenest pleasure in conveying to others the knowledge he has himself acquired. And yet I grieve to say that I have met several men who were strangers to this better feeling. When first I took up the study of Ferns, I asked many questions of one of the best cultivators of this tribe in his time, and always obtained an answer to the effect: "Ah, lad, it cost me money to learn that." I have lived long enough to see him left far behind in his acquaintance with these plants by many to whom he refused to give a single idea to help them on their course. The man at whose feet I learned first to trace out the characters in which the history of our globe is written on the stony pages of its own crust, was in some respects not unlike Mr Dick. Although very reserved, so devoted to science as to neglect his own business, and so uncommunicative that he could never rise to his proper position in the world (and, as a matter of course, the world did not know what his proper position was), yet I never shall forget how perseveringly he led myself and a fellow-apprentice on, teaching us to glean our own facts in the great field of nature, and showing us gradually how one fact led us on to another. I often think of how the good old man taught us to learn the lessons which the poor broken scraps of fossils we found at first could teach; nor shall I forget the joy with which he picked out a fossil Nautilus, almost unique, which we brought back from one of our scientific rambles among the hills. But the dear old man would hardly open his mouth to any one who could not converse with him on his favourite studies. Had the case been otherwise, he might have risen to some considerable eminence. While I would caution any youthful aspirant against the belief that a fortune is to be obtained by a study of science, I should fall into as great an error on the other hand, if I did not strongly urge one and all to devote themselves to it as energetically as they can: first, because of the pleasure it will give them; secondly, because it will assist them in their business, by enabling them to understand the *rationale* of the operations they are hourly called upon to perform. The engineer in 'Mugby Junction' says, "It's almost as good as being clever, to be fond of your business;" this is true enough, and no man will ever make a good gardener, or rise to any prominent position among his brethren, unless he be really fond of his business.—(*The Gardener.*)

NOTES AND GLEANINGS.

We have heard with no ordinary feelings of regret that Captain Cockerell has sent in his resignation to the Council as Assistant Secretary of the Royal Horticultural Society. All who have known Captain Cockerell, and those who have been brought into communication with him, can testify to the uniform kindness and courtesy he has always exhibited in the execution of his official duties; and those only who have had experience of the official management of the Society in former years, with the exception of the period when Mr. Booth so well filled the same situation, can fully appreciate Captain Cockerell's kindliness of manner, obliging disposition, and gentlemanly bearing.

—— Every one interested in the culture of Orchids will especially regret to hear of the death of Mr. George Ure Skinner. Although occupied by commercial pursuits, being one of the firm of Klee, Skinner, & Co., of Guatemala, yet he found time to pursue his favourite researches in natural history. His residence in Central America probably led him to the particular study of Orchids, with which the forests of the district abound, and with them his name is now thoroughly associated. For about thirty years we have known him engaged in their collection, and some one of their genera should do honour to his name. Cattleya Skinneri is a minor remembrance of him. One genus, worthy of him, records two of his names, but it belongs to the Natural Order Scrophulariaceæ. We refer to *Uroskinnera spectabilis*, thus mentioned by the late Dr. Lindley:— "For this beautiful plant our gardens are indebted to G. U. Skinner, Esq., the most generous of merchants, the most eager of collectors, to whom or to whose assistance the botany of Western Mexico and Guatemala owes more than to all the travellers who have visited those regions. Nothing more worthy of his name could well be found, for the plant is very rare, very showy, and now secured to our gardens; we therefore trust that verbal pedants will not quarrel with the manner we have contrived to escape from the difficulty of there being already a *Skinneria* in the botanical field, but agree with us that Ure Skinner may be fairly blended into a name which shall unmistakably record the labours of one who ought never to be con-

founded with any other Skinner whatever." He died of yellow fever on the 9th of January at Aspinwall, Isthmus of Panama, at the age of 62; and it adds painfully to the feeling for his loss to know that he was journeying to Guatemala to complete arrangements for retiring from the firm, preparatory to taking up his residence in England permanently.

He was a native of Scotland, and his father, the Very Rev. John Skinner, was Dean of Dunkeld and Dunblane, who died at Forfar in 1841, and who was son of Bishop Skinner, Primus of the Episcopal Church of Scotland. The Bishop, we believe, wrote the well-known "Reel of Tullochgorum."

Mr. Skinner, whose death we now record, was not only a Fellow of the Linnean and other kindred Societies, but was ever ready by his counsel and his purse to aid others who were pursuing the sciences those Societies fostered. He advised with Hartweg as to the latter's researches in Mexico; and he supplied Warscewicz with money at the time of his extreme need, when he had been abandoned by the Belgian Association, which had sent him to South America to collect plants.

WORK FOR THE WEEK.

KITCHEN GARDEN.

See to the due preparation of ground for crops in general, but beware of carrying on these operations when the soil is in a wet state, better be a fortnight too late with any crop. I am of opinion that where kitchen gardens are composed of light soil, it is better dug or trenched some weeks before it is wanted for some crops, especially Broad Beans, which like a firm hold of the soil. A small plantation of Marshall's Dwarf Prolific or of Mazagan *Beans* may be made as soon as the weather is favourable for the operation. *Peas*, when the first sowing is coming through the ground it will be advisable to draw a little earth to the plants. In the case of mice attacking them, there is, perhaps, no better remedy than trapping; the old figure-4 traps, a number of which can soon be made, are as good as any. Those who have not already sown Peas may make a sowing of any good early sort in the warmest part of the garden, on the first favourable opportunity. Take care, however, that the ground be previously dug to a good depth, or trenched, and in tolerably good heart. As Peas sown at this period of the year, especially in clayey soils, are liable to rot if buried too deeply, do not cover them more than 2 inches. *Parsnips*, sow as soon as possible. The ground should be trenched and manured in the autumn. Sow in shallow drills 18 inches apart. *Tomatoes*, sow in heat directly; also, *Sweet Basil*, *Sweet Marjoram*, *&c.* *Sea-kale* and *Rhubarb* for next year's forcing should be planted immediately in rich trenched ground. Throw a hillock of old tan, ashes, or sand, round each crown to coax it on through the vicissitudes of March and April. Where water is apt to stand on the surface through the puddling properties of heavy rains, try to improve the texture by a dressing of sand, ashes, lime rubbish, charcoal dust, &c.

FRUIT GARDEN.

Remember to drain thoroughly. Nowhere is this advice more necessary than in the orchard. Although Apples and Pears are fond of adhesive soils, they will never prove profitable where water is allowed to accumulate. Thin-pruning is also of great use to Apples which are rather free setters; it is likewise of great service to varieties of the Nonpareil class to enable them to perfect both fruit and wood. The stems of fruit trees on which moss or the hiding-places of insects are apparent should be cleansed. For this purpose brushes varying in stiffness according to the hardness of the bark should be employed. Those made of brass or iron wire will be found well adapted for scrubbing old crusted bark. The scale may be dislodged to a great extent by such means, and the bark freed from myriads of parasites, animal and vegetable, which prey upon its substance and render it unsound and unsightly. Moist weather facilitates the operation. Prepare clay for grafting, by mixing it with a portion of cowdung and a little fine hay. The pruning of wall trees on south aspects should be completed as soon as possible. In this climate every bearing shoot of the Peach and Nectarine requires to be shortened, otherwise a sufficient supply of young wood for future bearing cannot be insured; but if this has not been done there may be some difficulty, in consequence of these shoots having formed no wood-buds, except, of course, the terminal bud. In that case it will not be acting too severely to cut back at least every other shoot so fully studded with blossom-buds to within half an inch of the base, in order that from thence better shoots may spring, for after this reduction the number of blossom-buds left will, doubtless, be ten times greater than the number of fruit which the tree ought to bear.

FLOWER GARDEN.

Improve as much as possible all outlines. Plant fresh masses or groups when necessary, and introduce specimen plants when fitting opportunities offer. Much mischief is done by planting single specimens in recesses. These should be carefully preserved as a general rule, to give deep shadows and to throw the prominent features into bold relief. Top-dress Auriculas, delay it not while the weather is fine. Remove early blooms, and if any plants look sickly examine the roots; if from canker, apply the knife; and if from inefficient drainage, put more into the pot, if possible, without breaking the ball of soil. Tulips are coming forward, shade carefully from frosts and cutting winds. Continue to watch for leaves that are cankered, and remove them as soon as perceived. Top-dress the beds of Pansies with decayed leaves and manure from the Melon-pits reduced to a black unctuous compost; peg down or remove all straggling shoots, and place bran under tiles as a decoy for snails, &c., which will now, on mild nights, begin to be troublesome.

GREENHOUSE AND CONSERVATORY.

It is somewhat difficult to give directions in a successful way for mixed greenhouses. Plants of all climates will occasionally obtain a place there; and as no special treatment in regard to temperature may be long indulged in with impunity as to the plants from warm countries, a compromise of some kind must continually take place. As a principle, therefore, of frequent and somewhat harmless application, a rather free increase of heat should be allowed on sunny days early in the afternoon for a few hours, letting the temperature sink at night to the old point, or nearly so. In this structure there will frequently be found Ericas, Pelargoniums, New Holland plants, bulbs, &c., and even Orchids. We would, therefore, advise a division of these families; let the Orchids, bulbs, and plants of hot climates occupy the hottest end with little air, and the Ericas the other with a free circulation of air; the Pelargoniums may stand midway. The conservatory should now be of great interest. Any Camellias done blooming should, if possible, be removed forthwith to some of the houses at work; a moist atmosphere, a temperature averaging 65°, and a canvas shading overhead, are the requisites in order to cause them to produce wood freely and large leaves; the shading must by no means be neglected. The climbers in this structure should have a thorough dressing at this period, cutting away weak and decayed wood, and shortening back shoots. As a general rule, plants in flower require more water than those not in flower; it is not intended that they require to be deluged with water, but they should be very carefully and regularly supplied, or possibly the bloom of many plants will fall off prematurely. Again, they must not be exposed to currents of air; these, indeed, should not be admitted in any situation where exotic plants are kept at this time of the year, for they have no other effect than that of paralysing the vital action of the plants within their influence, and, therefore, while they are hurtful to all plants and flowers, they are especially so to such as have been produced in a close warm atmosphere. Again, the decayed and decaying flowers must be sedulously removed: this is necessary, no less on account of neatness and order, than for the purpose of preventing the injury or decay of the undeveloped flowers, which would be liable to injury by contact with those which were in a state of decomposition.

STOVE.

Some little increase of temperature may now take place here, and that chiefly, as before observed, in the afternoon by shutting up early and using plenty of moisture, taking care to thoroughly dry the foliage previously by a free circulation of air. Look over the fastenings of Orchids on blocks or in baskets, renew the wires where necessary. Fasten a little fresh material on those not to be shifted, but beware of burying the buds on the eve of their becoming developed. Apply baits for snails and cockroaches most assiduously, and attend closely to the extirpation of all scale. Examine and shift when necessary stove plants in general, and cut back some of the kinds after flowering to make cuttings.—W. Keane.

DOINGS OF THE LAST WEEK.

KITCHEN GARDEN.

With heavy rains and boisterous winds the weather has still been favourable for much out-door work, and where the ground

was light much could have been done in Bean-planting and Pea-sowing. For reasons several times given, we prefer planting out the earliest crops, and last season having no small wire guards we planted out nearly the whole of our crops. The routine as regards digging, trenching, and forward vegetables was much the same as detailed last week.

Collecting Leaves after the shooting season formed a part of our work, and we have been unfortunate this year and last. Both before and after that time the excessively high winds took off the leaves into the surrounding country, and what are left, owing to the heavy rains, are very wet, entailing, if thus collected, two disadvantages: the first, the great additional weight which has to be carted; and the second, the necessity of using them sooner, as there are no means that can be well used for preventing heaps of such leaves from fermenting and gradually decomposing. Under such circumstances leaves are vastly more expensive for heating-purposes than stable-dung when it can be procured in good quantities. The leaves, however, have these two advantages: they need but little preparation for being used as hotbeds, and then, when reduced to leaf mould, they are very useful as a component part of many of our composts. When leaves can be collected and stored in a dry state they will keep as long as it is desired without fermenting, but then we can always obtain heat from them by moistening them sufficiently to cause fermentation and consequent slow decomposition. For general matters see previous week's notices.

FRUIT GARDEN.

We previously mentioned throwing thin limewash over our Gooseberries, Currants, and dwarf bush Pears, Plums, &c.; hitherto it has been successful in keeping the birds from the buds, and we should like to repeat the process, especially on Pears, as the buds are swelling fast, and the recent storms have washed off the most of the lime. It still adheres pretty well to the Gooseberries as their shoots were less exposed, from being drawn pretty closely together in the bush faggot style. The intention is to remove the string and allow the bush to take its more natural position after the buds have fairly broken, as when in leaf the birds will cease to molest them. Whilst thus tied it is also easier to scrape away the soil from round the base of all the bushes, draw it into the space between the rows, and dig down that soil deeply there, whilst fresh soil is placed round the bushes, and the ground near the stems is merely forked over thinly. If there should be any products of caterpillars from last season, the digging them down deeply will generally destroy them. From this simple plan we are seldom troubled with the caterpillar. Were we near a tan pit we would put two or three spadesful of tan round each bush, as that seems to destroy all eggs and larvæ, at least when we could adopt that plan we were never troubled with caterpillars; but the fact would require to be more generally confirmed before we were thoroughly certain that the tan and the absence of the caterpillar were established as cause and consequence. It is possible for us at times to think we see the connection between results and causes, when in reality there may often be merely coincidence. As to the caterpillar that in fine summers is so apt to attack all the Brassica tribe, we know of no preventive equal to hunting down the white butterfly by a couple of sharp boys, spurred on by the desire of boxing the greatest number.

Raspberries.—We have tried almost every mode of training these—such as so many canes fastened to a stake, these stakes from 2 to 4 feet apart; tying them into the form of arches, either with a stake or without stakes, the canes when interlaced supporting themselves; but of late years we have generally fastened the canes in rows about 6 inches apart, the weaker ones being early cut away to give more room, sun, and air to those left. Of course we think this system the best on the whole, though the other plans have also much in their favour. On the line or row plan the plantation if in one place consists of rows about 5 feet apart, wooden stakes are placed along the row 4 or 5 feet apart, and on these light rods or saplings are fastened, one line about 15 inches from the ground, and the other about 3½ feet from it, and to these the canes are tied. This is the simplest mode of carrying out the line or row system; but as a Raspberry plantation will last in good order for a number of years, the best and the most economical mode in the end for training Raspberries on this plan is to have a few slight iron posts, and have three strained wires for fastening the canes to them, and then at all times the Raspberry plantation will look neat and handsome, which it frequently does not with our makeshift modes of management. Even when this appears, we shall not be more than in the middle of the month, and since the storm fruit trees of all kinds seem to be earlier than usual, many buds already becoming very prominent. Can this be owing to the heavy warm rains before the severe frosts, or to the rather warm rains that have fallen since? Singularly enough, too, we notice that the dull wet summer and autumn of 1866 have not done much in lessening the quantity of fruit-buds on fruit trees in general.

For orchard-houses, Peach-house, Strawberries, &c., see notices of previous weeks. Some time ago we put a little warm litter on the border of the first vinery, placing the cold litter that had been put there in the autumn on the surface, and protecting it from heavy rains. As soon as we have the material we will treat the second in the same way. The heat given off there, if at all sensible, will be used for forwarding many things in the early season by placing some old sashes over the border. If the temperature for forcing-houses is raised very gradually, and the atmosphere kept tolerably moist by damping the floor, stages, &c., there will be less necessity for syringing the trees so much as is generally done. We have come to the conclusion that this sprinkling, so often repeated, has little or no influence on the regular breaking of Vines, and we first began to find this out from the unwillingness to wet the leaves of plants beneath the Vines, when the plants were of such a nature, or in such a condition, that we would have preferred the foliage to be dry in sunshine.

ORNAMENTAL DEPARTMENT.

When the weather would permit, slightly rolled the lawn to keep wormcasts out of sight, and dug and ridged the centres of large beds and borders, leaving the sides near the turf for drier and better weather, when making up edgings. Even with a board at the grass edgings it would scarcely be possible for the men to trample on the grass near the beds without injuring it; and as a general rule it is best to avoid doing work in such times and ways as will be sure to make work, when better arrangements would render the most of that extra work unnecessary.

Pansies, Pinks, Carnations, &c., out of doors, will require firming about the plant after the frost, and to be protected from slugs and grass mice. Ranunculus and Polyanthus in a pit or frame will want all the air possible, without the rains, and to be top-dressed with rich, sweet compost. Violets, especially the Neapolitan, will want plenty of air in fine weather. As respects *Neapolitan Violets*, we did last season what we will most likely never do again—left some lights that were planted in the autumn of 1865, but without lights last season until the autumn, and though they looked nice, they do not produce as yet so freely as younger plants, yet they seem to have plenty of buds on them. What we consider the best and the easiest way to obtain fine-flowering plants of the Neapolitan, is the following—About May, take up the old plants; tear them into pieces, so as to have roots to each separate piece; trim the roots, if more than 2½ inches long; prepare a piece of ground by digging, and manuring with sandy loam and leaf mould; plant the pieces from 6 to 8 inches apart; stir the soil, keep clean, water as needed, and above all, allow not a single runner to grow all the summer, and then in the autumn either set a frame or frames over the plants, or take up and plant in a bed to be covered with glass, and if wanted particularly in bad weather in winter, fill some seven-inch pots with good plants, and set them where they can have a mild bottom heat, and a cool, rather dry atmosphere. If mildew in autumn, or red spider in summer make their appearance, dust with sulphur, and use the syringe freely. No older plants will equal those thus annually renewed. All the other single and double blue and white Violets, are best when treated in a similar way, and should not stand more than two seasons in the same place, if the greatest produce in flowers is aimed at. Potting and regulating plants much the same as in previous weeks.

Storing Turf for Potting.—As soon as the weather is dry we must see to this work, but it is often difficult to accomplish, and when short of turf, we generally contrive to obtain some good fresh soil from the ridges thrown up by the sides of highways and other roads, and which, consisting of the soil of the surrounding district, if that is at all loamy, and the ground flints and stones, makes a capital soil for the culture of most of our common pot plants; but even that we do not consider quite so good for the staple of the compost, as rich fibry turf that has stood in a narrow ridge for a twelvemonth, and has thus become sweetened. We feel obliged to Mr. Pearson for what he says and has done with fresh turf, and can bear out most of it, from what we have practised with certain turf for borders,

as well as for the bottom part of large pots, preferring more mellow soil for the surface, chiefly to have no trouble with the fresher causing a green surface. For general purposes of potting we prefer turf that has been taken up from six to twelve months, and has been piled in narrow stacks with air-vents through it. In such cases the fibre is but little reduced, the sour smell has disappeared, and the soil comes out dry, mellow, and sweet as a nut. For many commoner purposes, however, we would follow Mr. Pearson's example, if we obtained the right turf, and here we will give a test to the inexperienced, and Mr. Pearson will correct us if he do not coincide. Turf taken from upland pasture where the grass is of a bristly needle-like character, may be used at once, as the soil will generally be sweet beneath. We have often scarified the turf from such places—that is, taken it off as thin as possible, and used it for the bottom of large pots, and the fibry soil immediately beneath it for general potting purposes. Turf like this, however, cannot always be had, and we must often be content with what we can find. In lower levels the turf will often consist chiefly of grass, broad and softer in the leaf, having comparatively little fibre beneath it, and the soil though rich will often contain more acid—that is, smell unpleasant, and want more exposure before using it for particular purposes. This is far inferior for potting-purposes to the other, and, having more of a tendency to run closer together, needs something to keep it open. We often were amused when young, to see gardeners smelling their composts, but we have learned since that it is well to use the nose, as a test of the sweetness of soil for potting.

Furnaces under Boilers.—We will now offer a few remarks to meet the case of those who say their boilers and hot water are vastly more expensive as regards fuel than they were led to expect. Heating by hot water will always be more expensive in proportion to the little that is done by one furnace. Of course, when a dozen houses are heated from a dozen boilers there will be a greater escape of heat from a dozen chimnies than from one, two, or more. All that can be done, is to economise the heat, by keeping it as much round the boiler as possible. Lately, the mode of lighting a furnace was alluded to. Except when cleaning, lighting, and adding fuel, the furnace door should *never* be open. When the fire is fairly burning, the ash-pit door should be shut, leaving only a very small opening to admit air to reach the fuel through the bars. When the heat is well up, the damper should be put in, just allowing a slight opening to insure a slow draught. Even when a fire is about gone, a shut damper and close furnace and ash-pit doors will keep for a long time about the boiler heat which with a free draught would be dispersed quickly through the furnace, past the boiler, and up the chimney. It is by no means uncommon to find a damper right out, a chimney so hot that you can scarcely touch it, a huge red fire in the furnace, with the furnace-door open, so that the fire may give out plenty of heat to the stoke-hole, to the external air, and the little as it may be wanted to the boiler; and when fuel can be had for little more than the carriage, there may not be so much to be said, as a little less care and trouble will be necessary; but every such case of extra hot chimnies, open dampers, open furnace-doors, and huge fires not wanted, shows clearly that it is the system of the manager, and not the system of hot water that is mostly to be blamed for such waste of fuel.—R. F.

COVENT GARDEN MARKET.—February 13.

We have little or no alteration to report, having abundance of everything at present. Continental supplies are steady and good, and home-grown produce comprises the usual varieties in season at this period of the year.

TRADE CATALOGUES RECEIVED.

W. Samson & Co., and W. & T. Samson, Kilmarnock, N.B.—*General Catalogue of Vegetable, Flower, and Field Seeds, Plants, &c.*

Drummond Brothers, 52, George Street, Edinburgh.—*Catalogue of Vegetable and Flower Seeds.*

John Foulds, Stretford New Road, Manchester.—*Catalogue of Plants and Cuttings of Chrysanthemums, Zonale Pelargoniums, and Bedding-out Plants.*

TO CORRESPONDENTS.

*** We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed *solely* to *The Editors of the Journal of Horticulture, &c.*, 171, *Fleet Street, London, E.C.*

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

N.B.—Many questions must remain unanswered until next week.

Fig Culture (*J. F.*).—There is no work devoted to the subject. If you send five postage stamps with your address, you can have "Fruit Gardening for the Many," free by post from our office. It gives the necessary directions for Fig culture.

Wild Flowers (*Mrs. Rose*).—The work will be completed as soon as all the native plants have been figured.

Forcing Flowering Plants (*Dulcibella*).—Forcing flowers, fruits, and vegetables will be fully noticed in our pages before many weeks have passed.

Hays's Constant Stove (*J. R. Beyton*).—The 60s. one would be large enough to exclude frost from your small greenhouse. A bushel of the fuel would last a week. Common charcoal would not answer.

Growing Plants under Standard Roses (*An Amateur Rose Grower*).—Roses are jealous plants, and do not like any competitor close to their roots. They will in hot weather eat up any quantity of manure, and, drink up any quantity of water. Decayed manure covered with ashes is the best protection for their roots in hot weather. The ashes retain as well as attract moisture. If the querist wishes to put anything over the roots in the shape of flowers, Mignonette is the best, and gives a nice scent.—W. F. Radclyffe, *Okeford Fitzpaine.*

French Acclimatising Society (*J. B. B.*).—The address is, "To the Secretary, Jardin de la Société d'Acclimatation, Bois de Boulogne, Paris."

Rain Gauge (*A Needham*).—Rain gauges are only to be purchased of mathematical instrument makers, and they do not vend cheap articles. Any tinman can make a circular tin funnel a foot in diameter, and this may be placed in an upright glass measure 6 inches in diameter, with a scale marked in tenths of an inch on its side. The depth of rain shown on the scale divided by 4, gives the amount of rain. The glass measure may be bought of the chemical apparatus dealers.

Climbers for Walls of Dwelling (*C. M.*).—*North* aspect: Ivy, Cratægus pyracantha, Jasminum nudiflorum, and common Virginian Creeper (Ampelopsis hederacea). *East* aspect: Cotoneaster Simmonsii, Cydonia japonica, Photinia serrulata, double-flowering Clematis viticella, C. lanuginosa, C. flamula, C. azurea, Caprifolium sempervirens, C. periclymenum, Atragene sibirica, and Jasminum officinale grandiflorum; also Ayrshire Roses, Dundee Rambler, Ruga, Queen of the Belgians, and splendens. *West* aspect: Escallonia glandulosa, Viburnum suspensum, Buddlea globosa, Chimonanthus fragrans, Aristolochia sipho, Jasminum revolutum, Clematis Jackmanni, C. standishi, and Caprifolium luteum; also Roses—Hybrid China, Vivid; Bourbon, Sir Joseph Paxton, Acidalie, and Bouquet de Flore; Hybrid Perpetuals, William Jesse, La Reine, Madame Louise Carique, Madame Trudeaux, and Madame Domage; Tea, Gloire de Dijon, Noisette, Celine Forestier, Jaune Desprez, and Triomphe de Belwyller. *South* aspect: Wistaria sinensis, Billardiera scandens, Passiflora cærulea, Magnolia grandiflora, Exmouth variety, Garrya elliptica, Chimonanthus grandiflorus, Ceanothus rigidus, C. floribundus, and C. azureus, to which you may add Maréchal Niel and Climbing Devoniensis Roses; also Fortune's Yellow, Cloth of Gold, Lamarque, and Ophirie.

Collecting Debts (*W. L. E. Y.*).—The County court is open to you. Six years does not exclude you from the remedy.

Stopping Vines (*J. H. W.*).—1st, When the shoot is sufficiently long to show the bunch and the next joint above it, pinch out the point immediately above the leaf at the joint next above the fruit. 2nd, The floors of the house should be kept damp for some time after the Grapes begin to colour, but not when they are becoming ripe. 3rd, It would not injure the roots to lay a path with gas tar, further than by preventing rain passing through the walk, and if the latter is not wide tarring it will not make much difference.

Cyclamens Frosted (*C. M. Major*).—The best course to pursue is to leave them as they are, neither drying them off nor trying to induce fresh growth. It would not do to dry them off as the growths are not mature, nor excite them, as that would weaken the corms. Treat them as if they had not been frosted and they will gradually recover. We have Cyclamen vernum and C. coum in full bloom on rockwork, and none the worse of the late severe weather. We presume yours are C. persicum, which is not hardy.

Cutting Down Zonale Pelargoniums (*Calcaria*).—You should gradually withhold water, and cut the plants down early next month, repotting them in smaller pots when the new shoots are an inch or two long. Shift in May into the blooming pots. It will answer better than top-dressing.

Viola cornuta, Mimulus cupreus, and Pansies Sown in Heat (*A Subscriber*).—Plants will flower towards the end of July, and later, if raised from seed sown now in a hotbed. When large enough to handle they should be pricked off an inch apart in pans and grown on, hardening them off and planting them out in the end of May or early in June. They should be kept near the glass to have them strong.

Lilium tenuifolium, L. auratum, and Tritoma uvaria Seed Sowing (*Idem*).—The seed should be sown early next month in pots or pans, well drained, in a compost of turfy loam, peat, and leaf mould, with the addition of one-sixth of silver sand. The seeds should be covered with fine soil to a depth equal to the diameter of the seed. The pots should be gently watered and placed in a hotbed with a temperature of 70°. When the plants appear admit air and harden them off or remove them to a vinery at work, where they should be placed in a light, airy situation. If there is not a vinery at command, remove them, to a greenhouse. Keep them well supplied with water, and in September gradually withhold it, discontinuing the supply after October, all but a little now and then to keep the soil moist, but not wet. The Liliums should have the seeds placed so far apart that they can grow in the pots or pans as sown, an inch will suffice; but the Tritoma plants should, when large enough to handle, be potted off singly in small pots, and the soil in these should be kept moister in winter than for the Liliums. The Liliums, also, should be potted in November singly in 4½-inch pots, or three may be placed in a seven-inch pot. They should be kept in a cool greenhouse.

Tussilago farfara variegata for Bedding (*Idem*).—This is a rather effective and certainly pleasing and curious variegated hardy perennial. It answers for bedding, and will grow well in a position where it does not receive the mid-day sun. It will grow anywhere.

Ornamental-foliaged Annuals (*Idem*).—The most attractive of these are half hardy, or requiring to be grown in heat previous to planting out. Ricinus sanguineus, R. communis, R. borbonensis, and Zea japonica variegata, which all grow 5 or more feet high; Perilla nankinensis, Amaranthus melancholicus ruber, and Cineraria maritima, which grow 1½ to 2 feet; the variegated Marvel of Peru attains a similar height, and is handsome. Oxalis corniculata rubra (tropæoloides), is a very neat plant for an edging to such a bed as you propose.

Caladium Rootstocks Decaying (*T. Oliver*).—We think you have kept them too dry and in too low a temperature, either of which conditions will cause them to become "mellow" both at the crown and at bottom. They should remain in the pots as grown after they die down, and stand on a moist floor, or in a position where the soil in the pots will not become dust dry; but the pots should not be watered, though a skiff from the syringe once or twice a-week over the pots will keep the roots fresh. The temperature should not be less than 60° to winter them safely. The "mellow" rootstocks will most probably rot if they are not already rotten, especially those gone at the eyes; those decayed at the base may yet have the upper part or eye portion sound, and if so they may grow. Pot them, and place them in a bottom heat of 70° and top heat of from 65° to 75° or 80°.

Vines Unfruitful (*J. W.*).—The roots of the large Elm trees will, of course, injure your Vine border. The best plan is either to keep a deep open trench outside the wall, or build a deep wall in cement, to keep the Elm roots out. As the Vines have broken so strongly, however, we do not think the Elm roots are so much to blame, but rather incline to think that the comparative barrenness is either owing to the roots being too deep, or the wood being imperfectly ripened last season. Probably a little more hardening of the wood by extra firing in the dull autumn would have made all right.

Heating Small Plant-house (*Frozen-out*).—We should prefer a gas stove with a tube for the fumes from it to pass into the open air. You can increase or diminish the heat of that by merely turning the tap. We are sorry that No. 269 is out of print, but you can see our office copy any day that you call. We have no pity for those who have their gas apparatus frozen; they should have the meter in a place not liable to a freezing temperature.

Pine-apple Culture (*B. C. K.*).—"The Pine-Apple Manual" can be had free by post from our office if you enclose thirty-two postage stamps, with your address.

Best First Early Potato (*J. L.*).—We are informed by many reliable authorities that the Coldstream Early is the best of the earlies, both in quality and prolificacy.

Drying Specimens (*Hortus siccus*).—Laid flat and covered with sand, dry in a gentle heat, and then preserve between sheets of cartridge paper.

Erratum.—In our last we inadvertently stated that the new edition of the "Miniature Fruit Garden" was the 15th instead of the 14th.

Names of Plants (*W. J. P.*).—1, Polystichum, probably P. aculeatum; 2, Asplenium flaccidum; 4, Gymnogramma chrysophylla. (*T. T.*).—1, Pellæa adiantifolia; 2, Adiantum hispidum; 3, One of the garden hybrids between Gymnogramma chrysophylla and G. calomelanos; 4, Nephrodium setigerum; 5, Gymnogramma ochracea; 6, Cheilanthes hirta; 7, Gymnogramma chrysophylla; 5, Blechnum occidentale; 9, Gymnogramma ochracea; 10, Gymnogramma peruviana. (*C. A.*).—1, a Begonia, but species not detectable from such a scrap. 2, Abutilon striatum. 3, not determinable from a mere leaf.

METEOROLOGICAL OBSERVATIONS in the Suburbs of London for the Week ending February 12th.

Date.	Barometer.		Thermometer. Air.		Thermometer. Earth.		Wind.	Rain in inches.	General Remarks.
	Max.	Min.	Max.	Min.	1 ft. dp.	2 ft. dp.			
Wed. . 6	29.056	28.808	51	31	45	43	W.	.04	Boisterous and wet; clear; boisterous; fine.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

CHIEF CHARACTERISTICS OF THE PRINCIPAL SORTS OF GAME FOWLS.

(*Concluded from page* 95.)

The following sorts are not considered as sportsmen's birds, not being much used by them:—

Dark Birchens.—These are produced by crossing, and though like the Dark Greys, are softer, and not so good. They are, in general, produced from the Brown Red hens, crossed with either Dark Grey, Yellow Duckwing, or Yellow Birchen cocks. The first cross makes good birds; the Duckwing cross, which is most common, is not so good; and the Yellow Birchen cross is the worst. Dark Birchens often have olive green legs of a dark colour, and incline to the yellow skin.

Willow-legged Duckwings stand next, and are a well-known sort at exhibitions. These are the gamest of all the willow-legged, and are good, hard, strong, and courageous. They are considered by some a sportsman's bird, as they have sometimes, though not generally, beaten both Brown Reds and Cheshire Piles, but, being willow-legged and yellow-skinned, cannot be classed as a true cock-fighters' bird, as they always reject willow-legged and yellow-skinned birds, as not being Game enough to be good winners.

Willow-legged Black-breasted Reds are the most common and best-known of all Game fowls, and, though larger, strongly resemble the wild species known as the Gallus Bankiva of Java and India, which is of exactly the same colour. The Willow-legged Black-breasted Reds are an original, wild, coloured sort, and are the parent stock of the Willow-legged Duckwings, which were originally bred from the strongest and hardest of these Black-breasted Reds, which first threw the Grey hens, and subsequently the Duckwing cocks. These Black-breasted Reds have long been rejected by sportsmen as being too soft, and they have been often beaten by Brown Reds, Piles, Dark Greys, Duckwings, and all the sorts that have been previously enumerated and described.

Willow-legged Black-breasted Reds are the Game fowl of the agricultural districts, contrary to the Brown Reds, which are the Game fowl of the towns, and of the manufacturing districts. These Black-breasted Reds, in breeding, always throw a great many pullets in proportion to the cock chickens, a sign of softness; whereas the Dark Greys, Brown Reds, and other

sportsmen's sorts, always throw more cock chickens than pullets in proportion, a sign of their superior hardness and goodness.

Derby Reds.—These are white-legged Black-breasted Reds, with yellow or daw eyes, and dark yellowish brown hens, not Partridge-coloured, but fawn-breasted. They were the favourite Game fowls of the late Earl of Derby, and are called after him the Derby Reds. They are ranked by some as a sportsman's bird, being the quickest, most active, and lightest-fleshed of all the Black-breasted Reds; but like all yellow or daw-eyed birds they want stamina and endurance, do not stand the dubbing or trimming well, and are not so game as the true sportsmen's breeds are.

Another good strain with the yellow or daw eyes is a breed of white-legged Duckwings found in East Suffolk, and bred there by the late Lord Huntingfield, and called Lord Huntingfield's Silver-Grey Duckwings. These are as good as the best breeds of Duckwings to be found, and are very fine birds.

In the neighbourhood of Ipswich, Suffolk, I met with a breed of Red-breasted Ginger Reds, with bright red eyes, and yellow legs, with light Ginger Partridge hens, mostly spurred. These are the fiercest and sharpest Game fowls I ever saw, being more fiery than the best Cheshire Piles. They beat the East Suffolk Brown Reds easily, and are yet unbeaten in the eastern part of the county. This is an original colour, and is found in India. These Gingers, however, are not so hard as the Dark Greys and Brown Reds.

The Blue-legged Duckwings are game little birds, rather small, and distinguished for their fine sharp heads, having the sharpest heads of all the Game fowls.

Blue-legged Red Duns are also Game birds.

The Yellow-legged Duckwings are rather spiritless, like almost all yellow or daw-eyed Game fowls, but are handsome, and prolific. All the yellow, bay, and light brown-eyed birds are bad.

There are two slight errors in my communication at page 95. The word "Furnace" in the first column, twenty-eighth line from the bottom, should be "Furness;" and in the second line of the second column, for "southern" read "northern." —Newmarket.

COWS DROPPING AFTER CALVING.

My experience may be useful to some of your readers. I have kept a dairy of nine or ten cows, for private use, for about twelve years, and during the first ten years I was unlucky enough to lose, on an average, a cow a-year from the above casualty. Several veterinary surgeons were called in, but none of their nostrums ever succeeded in setting one of my cows on her legs again; so I determined to try my own plan, which is this. It is well known that the complaint arises from weakness, and inflammation of the uterus consequent on calving: so immediately the cow drops I have strong mustard rubbed along the spine; if costive, a dose of castor oil is admiuistered, and gruel and old ale given every two hours. I have saved three cows by this treatment; the last, a very valuable animal, dropped on Sunday morning, and appeared in a hopeless state until last evening, when she rose, and is now to all appearance doing well.

I may add that I only keep Alderneys, and think there is nothing like them for family supply. During winter they are kept in the house, only going out for an hour or so on fine days, and their food is hay, grains, and mangold wurtzel. They give an abundant supply of milk, and rarely suffer from cold.—C. A. Hanbury, *Belmont House, East Barnet.*

COCHIN-CHINA COCK'S TAIL AND VULTURE HOCKS.

Knowing your friendship towards us of the feathered fraternity, I take up one of my quills to address you on a matter of moment to myself and my brother Cochins. Though I am a chicken, I am a full-grown one, and am considered a fine bird. I was highly commended at Birmingham, and took a prize at Bristol. I have a fine handsome tail, not over-large, but standing proudly erect for 2 or 3 inches, and then falling gracefully backwards. What I want to know is if this ornament, of which I am so proud, is really no ornament at all, but an eyesore in the sight of good judges. I ask the question because I see my brothers at the show with most of their tails gone, and I am told it must be so with me if I am to take high honours. Is this so? and must I lose my beautiful top feathers? Then, again, I have a nice cluster of feathers at the top of my legs. Is this what is called vulture hock, and am I to be considered a "duffer" because of these? In every other respect, I am told, I am perfect. Your opinion on these matters will oblige —A White Cochin Cock.

[We do not hesitate to say that with experienced judges you will be admired, because you are shown, as they term it, honestly. Wherever it is patent that liberties have been taken, and feathers pulled out of a tail, disqualification should follow. We must, however, add that in all your breed, the tail should not be a prominent feature, and 3 inches high is quite high enough. There are many beauties which become deformities when they are exaggerated. Instead of carrying it proudly erect, we advise you to drop it a little. The handsomest members of your family endeavour to present the line of beauty by slanting down from the head to the middle of the back, then rising very gradually and very little from the middle. The tail merely describes a curve, and falls in waving feathers. Vulture hocks are generally considered as a deformity of your breed.]

MUTILATION OF FOWLS AT EXHIBITIONS.

In your Number published on January 31st, there is a letter, signed Thos. Wrigley, jun., Tonge, Middleton, Manchester, which I think reflects most unjustly upon the Committee of the Leeds Smithfield Club. I have the honour to be a member of that Committee, and I can assure Mr. Wrigley, jun., that every care was taken at the last Show to appoint proper persons to receive the fowls, to place them in the pens, to have them well and judiciously fed and attended to during the days of exhibition, and, at the close, to put them into the proper hampers and have them sent home. At the request of my fellow Committee-men, and with an earnest desire to do what I could for the Society, I undertook the responsible and arduous duty of penning the birds with the help of a good assistant, also of repacking them for despatch to their homes at the close. I say it without any egotism, that every bird was as carefully and properly handled as if the owner had done it himself. To guard against any mishap I waited into the small hours of the morning to receive any hampers that might arrive by rail, and did not leave till a messenger from the station informed me no more could come, as the trains were all in.

I then satisfied myself that all was ready for the judges, and left the place in charge of night watchmen specially appointed. I was there again soon after six the same morning, and found all right. I kept a constant and careful watch over the pens during the days of exhibition, in addition to the men appointed, and when the hour for closing arrived I had the place cleared of every one but the Committee and servants. The same assistant and myself immediately commenced to take out the birds and pack them in the proper hampers. That there should be no delay we kept at our work until after three o'clock next morning. We were very careful to note what pens each packed, and on referring to my memoranda I find that Mr. Wrigley's two pens of Golden-pencilled Hamburghs (all that he exhibited), were packed by myself. I also packed the whole of the Silver-spangled, so that I am in a position to state most positively that neither his birds nor the Silver-spangled chicken brought under his notice lost any feathers in our hands. I found a sickle feather in one of the Silver-spangled pens, and drew attention to it before I touched the bird; there was no doubt it had cast it. I also had my attention called to a sickle feather in one of the Black Hamburghs (sent from Mr. Wrigley's neighbourhood), which had been ingeniously fastened in with black silk to make up a deficiency. So much for sickle feathers. Excepting in the case of one Duck, which had been lost in transit, the Committee have not had a single complaint of birds missing or wrong birds received. I think this speaks for attention with a lot of about seven hundred pens.

I feel that the remarks of Mr. Wrigley respecting the Silver-spangled chicken are a gross libel upon our Committee, for there is not a single gentleman belonging to it who would demean himself to commit such a cruel and dastardly act as wilfully plucking "every laced feather from both wings," or any other feathers, and I think my explanation ought to prove that the Committee took every care no one else should do so. They do not know one person's birds from another; every exhibitor is alike to them. It is their aim and study to conduct their shows upon honest principles and with strict impartiality. After devoting so much valuable time from their business, and working so hard

for no personal benefit to themselves, I think it is base ingratitude to throw out such insinuations as those appearing in your correspondent's letter.—James Brabeck.

BRAHMA POOTRAS AT BRISTOL.

You have, with all the authority of editorial power, in your foot-note to Mr. Wright's letter ordered the combatants to be separated; but I crave a few lines of space—not to renew the battle in the slightest, but to express my own regrets that anything approaching personality, even in appearance, should have fallen from my pen, and further to express the wish that "differences of opinion may never sever friendship."

Further, I cannot rest contented with an amount of praise for my strain of Brahmas, which possibly I do not at all deserve. Let me explain. Mr. Wright would make it appear that I alluded to Mr. Boyle when speaking of a yard I had seen, the great success of which depended on some crossing with my own. I should be sorry, indeed, for this statement to go forth uncontradicted on my part. I have never had the pleasure of seeing Mr. Boyle or his birds. He had birds of mine some two or three years ago, in this manner: I hatched some chickens in January, 1863 (I think). They were shown at Basingstoke in May, where they were placed before several old pens; and after this, as I did not like the cockerel, who rather bullied his younger brothers, I sold the pen at a low price to the late Mr. F. Pease, of Darlington. He found that one pullet had not yellow legs. He sold the birds to Mr. Beldon, who exhibited them at the Newcastle Show, held in connection with the Royal Agricultural Society. There they were awarded first prize as chickens, and claimed by Mr. Boyle. One of the pullets was shown by Mr. Boyle in his second-prize pen at the Agricultural Hall. According to the opinions of many breeders, though second, the pen ought to have been first, and was placed first at Birmingham. This, at least, was the history given me by my lamented friend, Mr. F. Pease, in one of the last letters I ever received from him. How far Mr. Boyle used these birds in his yards I am quite unable to say, so that I wish clearly to say that I had not Mr. Boyle in my mind, but another friend, whose name, both as a Dark and Light Brahma-breeder, is very well known and constantly seen in our prize lists.—Y. B. A. Z.

SOUTH OF IRELAND POULTRY, PIGEON, AND CAGE BIRD ASSOCIATION.

(*From a Correspondent.*)

The sixth annual Exhibition of this Society, held in the Athenæum, Cork, on the 30th and 31st of January, was attended with considerable success.

The show of poultry, though not equal either in the number or quality of the birds exhibited to that division of the Munster Show, held in Limerick for the first time last December, was on the whole very creditable and encouraging to our Irish friends, composed as it was entirely of birds the property of Irish fanciers. The *Spanish* birds, not only so generally admired, but also so suited to the Irish climate, should be more attended to, as, with the exception of the prize pens and one or two others, the collection was not above mediocrity. *Dorkings* mustered very strongly, and were a superb class, in which Mr. O'Grady, of Bandon, showed largely and well. Miss Louisa Pike also exhibited a bird really unexceptionable. A little more depth of body is desirable in their Dorkings. Saving Mr. Zurhorst's deservedly-famous *Cochins*, which won Mrs. Lyons's medal, and a pen belonging to Mr. Williams, these birds deserve no notice. The same may be said of Dark *Brahmas*, Mr. Boyle's winners excepted, and the Light Brahmas should on their return home be consigned to the cook. Of *Crève Cœurs* some were very good. *Game* had improved since 1866, but were still deficient. Of White-crested and Gold-spangled *Polands*, one or two very excellent pens of each kind were shown, and of Silver-spangled Mr. Williams showed the remains of a famous strain, which I trust he will try and restore to its former excellence. *Hamburghs* increased in number and improved in kind. *Bantams* were poor. *Houdans* were numerous and improved, and the White-crested *Sultans* graced several compartments. *Malays* took the first prize in the Any variety class, the winner being represented by one of the best birds in the kingdom, from Mr. Cooper's large collection, and which has taken seven or eight first prizes at various English and Irish shows. *Turkeys* were few in number, but very superior, and the same may be said of *Geese*. In both these classes Mr. Cooper won all the first prizes. Aylesbury and Rouen *Ducks* were preseut in large numbers, and many, especially of the latter kind, had much merit. Mr. Cooper won the cup for most points in poultry.

In the *Pigeon* department a very large collection was shown, and one which, for the excellence of the birds exhibited, could scarcely be surpassed. The Ponters were of unusual merit, and most prominent in this class was Mr. A. W. Shaw's pair of Blues, taking first honours in a very superior collection. The Reds and Whites were also well worthy of attention, Dr. Harvey being first in the latter class. Carriers were numerous and excellent, especially the Blacks and Duns, and in the former I think that the second-prize birds should have been first. However, both belonged to Dr. Harvey, and I daresay he did not object to the decision. Blues were fair. The Short-faced Tumblers, more particularly the Almonds and winning Mottles, would have held their own at any show. The common Tumblers were a little behind, although this variety seems of late to have been much cultivated in Ireland. Barbs were extremely fine; some birds of good merit in the Any colour class, however, being a little out of condition, had consequently to be passed over. Jacobins and Fantails were good; but the former variety I prefer with pearl eyes. In Owls was a remarkably small pair of Whites, of African origin, which defy competition; other colours poor. Trumpeters were very fine, Mr. Perrott winning the medal for the best, but not without being closely pushed by Mr. Shaw. Turbits, Nuns, and Magpies were fair. The Any variety class brought out some new and rare birds, the German Toys, Isabels, and Frillbacks being my special fancy. In Pigeons Mr. A. W. Shaw won the medal for the greatest number of points.

I cannot close without mentioning the rare and valuable collection of Hawks, Cormorants trained to fish, Parrots, Cockatoos, &c., exhibited by Mr. Corbett, of Castle Connell. A larger or more valuable collection of fancy birds is not possessed by any one in Ireland. They were the centre of attraction, and added much to the success of the cage bird department, in which, however, many valuable song birds were exhibited.

This Show, under the management of the active and indefatigable Secretary and Treasurer, Frank Holder and J. C. Perry, Esqrs., and an able Committee of gentlemen to assist them, will, it is to be hoped, continue to improve, and with the Munster Show (which by the way our Limerick friends expect to make a great success next year, having already received promises of eight medals for the Pigeon department only), will prove of much benefit to the south and west of Ireland.—J. W.

[We published the prize list last week.]

NANTWICH POULTRY EXHIBITION.

The eighth annual Show was held on the 8th and 9th inst.; and according to the official list the following awards were made, but our own report is unavoidably postponed till next week.

Spanish.—Prize, J. Dean, Wharton. Highly Commended, R. Hulse, Winsford. *Chickens.*—Prize, J. Dean. Highly Commended, J. Siddorn, Over Lane.

Dorkings.—Prizo and Commended, T. Burgess. *Chickens.*—First and Second, T. Burgess. Commended, Mrs. Williams, Baddington.

Cochin-China (Buff).—First, Messrs. Church & Houlding. Second, W. James, Stapeley. *Chickens.*—First and Hon. Mrs. Sugden's Cup, W. James. Second, W. A. Taylor, Manchester. Third, G. Fell, Warrington. Highly Commended, H. Mapplebeck, Birmingham; Col. Stuart Wortley; J. Cattel, Birmingham; Rev. S. C. Hamerton, Warwick. Commended, H. Tomlinson, Birmingham; W. James. *Pullets.*—First, H. Mapplebeck. Second, T. Bott, Bury. Highly Commended, W. James; W. A. Taylor.

Cochin-China (White).—First, J. Dodd, Minshull Vernon. Second, G. Williamson, Nantwich. Highly Commended, J. Dodd.

Brahma Pootras.—First, J. Heath, Nantwich. Second, W. Johnson, Nantwich. Commended, W. B. Etches; Messrs. Church & Houlding.

Game.—Cup, T. Burgess. Second and Third, J. Fletcher, Stoneclough. Highly Commended, J. H. Williams, Welchpool; T. Whittingham, Batherton. Commended, W. Galley, Nantwich.

Game (Black Reds).—First and Second, T. Burgess. Third, J. Grocott, Haughton. *Chickens.*—Cup and Second, J. Heath, Nantwich. Third, J. Grocott. Highly Commended, J. Hulse, Cuckoo Lane; R. Ashley.

Game (Brown Reds).—First, T. Burgess. Second, J. Withinshaw, jun., Nantwich. *Chickens.*—First, G. F. Ward, Wrenbury. Second, G. Davenport, Nantwich. Third, T. Williamson, Nantwich. Highly Commended, P. Judson, Nantwich; T. Burgess; T. Hope, Newtown; H. Timmis, Walgherton. Commended, W. Fisher, Ravensmoor; T. Simpson, Nantwich; W. Clarke, Burland; G. Basford, Nantwich.

Game (Any other variety).—First, R. Ashley, Nantwich. Second J. Judge, Drayton. Third, Miss Sadler, Whitchurch. Highly Commended, Messrs. Church & Houlding.

Game (Any other than Black or Brown Reds).—*Chickens.*—First and Second, R. Ashley. Commended, R. Crewe, Burland.

Game.—*Cock.*—First, R. Ashley. Second, T. Burgess. Third, P. Judson. Highly Commended, J. B. Furber, Baddiley; W. Farmer, Nantwich. Commended, W. Sowerbutts, Nantwich; G. Williams, Acton; T. Burgess. *Cockerel.*—First, T. Whittingham. Second, J. Heath. Third, S. Edwards, Nantwich. Highly Commended, R. Ashley. *Hens.*—First, R. Ashley. Second, J. Walley, Larden Green. Third, G. Davenport. Highly Commended, J. Prince, Nantwich; G. F. Ward, Wrenbury. Commended, Messrs. Church & Houlding; T. Burgess; G. F. Ward.

Game Bantams.—First, R. Ashley. Second and Third, Messrs. Church and Houlding. Commended, G. F. Ward.

Bantams (Any other than Game).—Prize, G. Williamson.

Hamburghs (Pencilled).—First, G. Davenport. Second, W. Speakman, Doddington. Highly Commended, G. Williamson.

Hamburghs (Spangled).—First, G. Davenport. Second and Third, T. Burgess. Highly Commended, J. Hitchenson, Moulton. Commended, W. Lawton, Lawton Hall.

Polands (Any colour).—First and Second, J. Heath.

Ducks (Aylesbury).—Prize, Mrs. M. Hornby, Darnhall. Highly Commended, H. Haslam, Drayton.

Ducks (Rouen).—First, Messrs. Church & Houlding, Nantwich. Second and Highly Commended, T. Burgess, Burleydam.

Ducks (Various).—Prize, W. B. Etches, Woodhouse.
Turkeys.—Pres. Cup, C. Barnett, Blakenhall. Highly Commended, C. Barnett; T Burgess, Burleydam.
Geese.—Prize, T. Whittingham, Batherton. Highly Commended, W. Furnival, Sound.
Cottagers' Prize for the Best Pen of Cross-bred Fowl.—First, T. Moulton, Nantwich. Second, J. Bullock, Nantwich. Third, Mrs. Dodd, Minshull Vernon.
Selling Class.—First, G. F. Ward. Second and Third, T. Burgess. Highly Commended, J. Dutton, Bunbury. Commended, J. Heath.

SWEEPSTAKES FOR SINGLE COCKS.

Cochin-China.—Prize, W. James. Commended, H. Haslam.
Brahma Pootra.—Prize, Mrs. Galley, Nantwich.
Game.—Prize, T. Burgess.
Game Bantam.—First and Second, W. Griffiths. Third, T. Burgess.
Hamburgh.—Prize, J. Walley, Baddiley.

PIGEONS.

Carriers.—First, W. Cliff, Nantwich. Second, E. J. Butterworth. Highly Commended, W. Cliff; J. Chesters.
Dragons.—First, H. Prince, Nantwich. Second and Highly Commended, W. Cliff.
Pouters.—Prize, E. J. Butterworth, Nantwich.
Barbs.—First, J Chesters, Nantwich. Second, L. Glassey, Dod's Green. Highly Commended, H. Nixson, Dysart Buildings; W. Cliff.
Nuns.—Prize, J. Dutton.
Tumblers (Any variety).—First and Second, T. Cawley, Tarporley. Highly Commended, T. Cawley; A. Boote, Weston.
Fantails.—First, J. Dutton, Bunbury. Second, S. Worsey, Nantwich. Highly Commended, R. Green, Nantwich; E. J. Butterworth.
Jacobins.—Prize, L. Glassey.
Trumpeters.—Prize, J. Dutton. Highly Commended, H. Prince, Nantwich.
Owls.—First, J. Chesters, Nantwich. Second, E. S. Nixson, Dysart Buildings. Highly Commended, W. Brereton, Ravensmoor.
Turbits.—First, H. Prince, Nantwich. Second, J. Chesters.
Pigeons (Any other variety).—First, J. Dutton. Second, H. Prince. Highly Commended, J. Dutton; J. Chesters.
Doves.—Prize, J. Dutton. Highly Commended, W. B. Etches.
Selling Class.—First, Second, and Commended, J. Hokenhull, Nantwich.

A silver cup, given by G. W. Cooper, Esq., was given to T. Cawley as having the most perfect pen; and a prize of 10s. was awarded to J. Dutton, as having the most points in prizes.

SINGING BIRDS.

Canaries (Yellow).—First, H. Sumner, Nantwich. Second, Messrs. Skidmore & Williamson.
Canaries (Buff).—First and Extra, H. Sumner. Second, Messrs. Skidmore and Williamson.
Canaries (Any other variety).—First, R. Green, Nantwich. Second, J. Davies, Nantwich. Highly Commended, H. Sumner.
Linnets (Brown).—First, Messrs. Skidmore & Williamson. Second, W. Williamson.
Goldfinches (Red Linnets).—First, Messrs. Skidmore & Williamson. Second, D. Robinson, Nantwich.
Skylarks.—First, T. Simmons, Nantwich. Second, D. Robinson.
Bullfinch.—First, T. Robinson, Nantwich. Second, Messrs. Skidmore and Williamson.
Cage of Six Canaries.—First, H. Sumner, Nantwich. Second, Messrs. Skidmore & Williamson.
Rabbits (Long Ears).—First, W. Crawford, Nantwich. Second, W. Askew, Nantwich. Highly Commended, E. J. Pace, Nantwich. *Weight.* First, J. Robinson. Second, J. Simpson, Nantwich.

The Judges were—For Poultry, Edward Hewitt, Esq., of Sparkbrook, Birmingham, and William Teehay, Esq., of Fulwood, near Preston; and Charles Bowles, Esq., of Chester, officiated for Pigeons.

CRYSTAL PALACE BIRD SHOW.

February 9th to 15th.

Once again with feelings akin to pleasnre, we have to say our say about the annual Exhibition of British and Foreign Birds now being held at the Crystal Palace, and of which we were fearful the late disastrous fire might necessitate the postponement; but the large resources of the building, we are glad to find, have been equal to the emergency, and a most excellent show-room has been made by the conversion of one of the refreshment departments. The unfortunate destruction of the tropical end of the Palace is very much to be regretted, as the beautiful foliage of the plants is wanting "to lend enchantment to the scene."

We expended so much eulogium on the last gathering together of the feathered tribes at this place, that we are at a loss for words to convey our admiration of the Exhibition which we have just seen. It is truly a magnificent one, and such a one as has never before been witnessed, the specimens exhibited clearly showing that the attention requisite to keep a caged bird in health is quite understood. Nor are the little prisoners abashed at so much notice taken of them by strangers; some saucily carrol forth their sweet notes of welcome, others with notes failing sweetness, croke a kind reception to the visitors.

The collection of British and Foreign Birds is of rare excellence and beauty. Our native songsters are admirably represented. The Blackbird and the Thrush, the Linnet and the Goldfinch, the Nightingale and the pugnacious Robin, all may be seen in friendly communion.

The specimens of our little Bullfinch are very choice. It would be impossible to select any one specimen for special praise, so equal are they to each other in beauty and condition, as the distribution of the prizes and commendations bears testimony.

We will, however, point out one or two birds in the class of varieties noticeable as showing the strange freaks which dame Nature sometimes plays with her children. One specimen, a white Sparrow, is an oddity in which very few persons believe. However, we imagine it cannot be a London Sparrow; another, very rarely seen, considering the natural colour of the bird, is an albino Jackdaw. There are also a white Hedge Warbler, a white Bullfinch, and a pied Blackbird, Lark, and Linnet, and a most rare specimen of the Shore Lark.

The *Parrot* class is very fine, some of the Indian Lories being exquisite in colour. Our old friend, the White Cockatoo, which invariably carried off the prize for that class at previous shows, is absent. We hope that nothing has happened that has tended to shorten its days, as it was, indeed, a splendid representative of its tribe—a great favourite.

The show of *Canaries* is unparalleled in the number, beauty, and good condition of the birds. There are some very superb specimens, especially in the Norwich Jonque, the London Fancy, and Gold and Silver-spangled Lizards. The Jonque and Mealy Goldfinch Mules are stronger in competition than on any former occasion, and embrace many choice and elegant specimens.

Too much praise cannot be bestowed on the Superintendent, Mr. Wilkinson, for the very admirable manner, under the existing circumstances, in which the Show is managed. A considerable amount of judgment and thought is required to arrange so large a collection of birds so that they may be seen to advantage by the visitors, and also to enable the Judges to perform their duties satisfactorily, which we imagine must have been very onerous.

CANARIES.

Clear Yellow (Norwich).—First, H. Ashton, Manchester. Second, H. Vine, East Cowes, I.W. Third, W. Walter, Winchester. Equal Third, G. Y. Collinson, Thorpe Hamlet, Norwich. Very Highly Commended, J. Bexson, Derby; W. Walter; R. Mackley, Norwich; J. Judd, Newington Butts. Highly Commended, W. White, Nottingham; G. Y. Collinson; H. Vine; J. Pullen, Shoreditch. Commended, G. Y. Collinson; G. Moore, Northampton; W. Barnes, Cannon Street.
Clear Buff (Norwich).—First and Second, H. Ashton. Third, G. Y. Collinson. Very Highly Commended, G. Y. Collinson; J. Bexson; J. Pullen; W. Walter. Highly Commended, G. Y. Collinson; G. Cummings, Gloucester; W. Barnes. Commended, G. Y. Collinson; J. Pullen.
Variegated or Marked Yellow (Norwich).—First, Second, and Third, G. Y. Collinson. Very Highly Commended, J. Meredith, Kingston-on-Thames; G. Y. Collinson; W. Walter. Highly Commended, R. Mackley; H. Vine. Commended, G. Y. Collinson; R. Mackley.
Variegated or Marked Buff (Norwich).—First, H. Ashton. Second, G. Y. Collinson. Third, E. Orme, Derby. Very Highly Commended, W. Walter; J. Judd. Highly Commended, G. Y. Collinson; J. Pullen. Commended, G. Y. Collinson.
Marked Crested Yellow (Norwich).—First and Second, G. Y. Collinson. Very Highly Commended, G. Y. Collinson; J. Knibb, Northampton. Highly Commended, Mrs. M. La Touche, Berkeley Square; S. Tomes, Northampton. Commended, W. Walter.
Marked Crested Buff (Norwich).—First and Second, G. Y. Collinson. Very Highly Commended, G. Y. Collinson; R. Mackley. Highly Commended, G. Y. Collinson; J. Judd. Commended, W. Walter; J. Judd.
Clear Yellow (Belgian).—First, J. Poole, Sutton-in-Ashfield, Notts. Second, J. Hayes, Sutton-in-Ashfield, Notts. Third, J. Doel, Stonehouse, Devon. Very Highly Commended, J. Doel; Miss H. Maunder, Pinner; J. Hayes. Highly Commended, R. J. Troake, Bristol; H. Vine. Commended, W. Inson, Redland, Bristol; A. W. Booker, Allerton, Liverpool.
Clear Buff (Belgian).—First, J. Doel. Second, O. Nicholson, Landport, Portsea. Very Highly Commended, R. J. Troake; J. Hayes. Highly Commended, A. W. Booker; Miss H. Maunder; J. Hayes; O. Nicholson. Commended, A. W. Booker; J. Poole.
Variegated or Marked Yellow (Belgian).—First, J. Poole. Second, W. Inson. Highly Commended, O. Nicholson. Commended, Mrs M. La Touche.
Variegated or Marked Buff (Belgian).—First, J. Bexson. Second, W. Inson. Very Highly Commended, J. Poole. Commended, O. Nicholson.
Crested or any other Variety (Belgian).—First and Second, H. Ashton. Very Highly Commended, W. Walter.
Jonque London Fancy.—First and Second, J. Waller, Tabernacle Walk, Finsbury. Very Highly Commended, W. Brodrick, Budleigh, Salterton, Devon. Highly Commended, T. Mann, Langton Road, Camberwell New Road. Commended, W. Brodrick; J. Waller.
Mealy London Fancy.—First and Second, J. Waller. Very Highly Commended, W. Brodrick. Highly Commended, T. Mann. Commended, L. Corti.
German or any other Variety Except Norwich or Belgian.—First, G. Moore, Northampton (Buff Cinnamon-crested). Second, J. Wynn, Northampton (Buff Variegated Cinnamon). Very Highly Commended, S. Tomes (Crested Buff Yorkshire). Highly Commended and Commended, F. Schweiss, Hooper-square (German).
Golden-Spangled Lizard.—First, H. Ashton. Second, W. Vie, Derby. Third, W. White. Equal Third, F. W. Fairbrass, Canterbury. Very Highly Commended, G. Y. Collinson; T. Fairbrass; L. Corti; T. Robinson, Middlesborough-on-Tees. Highly Commended, G. Harrison, Canterbury. Commended, J. Hayes.
Silver-Spangled Lizard.—First, H. Ashton. Second, F. W Fairbrase. Third, G. Harrison. Equal Third, T. Robinson. Very Highly Commended, G. Y. Collinson; G. Harrison; B. Poynton, Old Basford, Notts. Highly Commended, J. Houghton; P. Flexney, Caledonian Road. Commended, T. Fairbrass; L. Corti.
Jonque Cinnamon.—First and Third, G. Goulter, Norbiton, Surrey. Second, J. Wynn. Very Highly Commended, R. Mackley; H. Vine. Highly Commended, S. Tomes; G. Moore; H. Marshall, Durham. Commended, J. Reeks, Walworth Road; J. Waller; G. Y. Collinson.
Buff Cinnamon.—First, H. Vine. Second, G. Goulter. Very Highly Commended, J. Wynn. Highly Commended, J. Reeks; G. Y. Collinson; H. Marshall. Commended, G. Tuckwood, Nottingham; G. Moore.
Jonque Goldfinch Mule.—First and Third, J. Doel. Second, H

Ashton. Very Highly Commended, J. Doel; H. Marshall; E. Coke, Derby; F. E. Coleman, Clapham Common; H. Ashton. Highly Commended, G Moore; H. Marshall. Commended, G. Moore; J. Judd.

Mealy Goldfinch Mule.—First, H. Marshall. Second, H. Ashton. Very Highly Commended, B. Poynton. Highly Commended, H. Ashton; R. Mackley; E. Coke. Commended, W. Heap, Bradford, Yorks.

Linnet Mule.—First, H. Marshall. Second, H. Ashton. Very Highly Commended, F. E. Coleman. Highly Commended, W. Heap.

Any other Variety of Canary Mule.—First, H. Marshall (Siskin Mule). Second, J. Doel (Black Mule).

Best Six Norwich Canaries in one Cage.—First, W. Walter. Second and Third, J. Judd. Very Highly Commended, G. Y. Collinson; R. Mackley. (The whole class highly commended.)

Best Six Belgian Canaries in one Cage.—First, J. Hayes. Second, Miss H. Maunder. Third, J. Judd. Very Highly Commended, J. Rutter, Sunderland. Highly Commended, R. J. Troake; W. Walter.

Best Six Golden-Spangled Lizards in one Cage.—First, G. Tuckwood. Second, J. Hayes. Third, Rev. V. Ward, Canterbury. Highly Commended, F. W. Fairbrass.

Best Six Silver-Spangled Lizards in one Cage.—First, H. Ashton. Second, G. Tuckwood. Third, J. Hayes. Very Highly Commended, B. Poynton. Commended, F. W. Fairbrass.

Best Six Goldfinch Mules in one Cage.—First, H. Marshall. Second and Third, H. Ashton. Very Highly Commended, J. Doel. Highly Commended, W. Walter. Commended, G. Moore.

Miscellaneous.—First, W. Heap (Hybrid Bullfinch Mule). Second, W. L. Chapman, Northampton. Very Highly Commended, H. Ashton (Goldfinch and Bullfinch Mule); W. Walter (Mule). Highly Commended. H. Hanley, Regent's Park Barracks.

BRITISH BIRDS.

Bullfinch.—Equal First, W. Walter; J. Judd. Very Highly Commended, H. Ashton; W. Newman, Norwood; Mrs. F. King, Upper Norwood; J. Judd; F. Schweiss; Highly Commended, F. Hunt, Upper Norwood; H. Vine; J. Wynn.

Chaffinch.—Prize, H. Vine. Very Highly Commended, W. Walter. Highly Commended, S. Hinds.

Goldfinch.—First, S. Hinds. Second, W. Price. Very Highly Commended, S. Hinds; J. Doel; W. L. Chapman; H. Vine. Highly Commended, O. Lipscombe, Westbourne Grove, W.; G. Cummings; J. Judd; C. J. Meredith.

Linnet.—First, H. Ashton. Second, H. Marshall. Very Highly Commended, O. Nicholson; Mrs S. Searle, Norwood. Highly Commended, J. Meredith; W. Walter; Mrs. La Touche.

Skylark.—Prize, J. Judd. Very Highly Commended, J. S. Benton, Rochester; J. Judd. Highly Commended, C. F. Johnson, London; H. Hanley.

Woodlark.—Prize, J. Judd. Very Highly Commended, C. F. Johnson. Highly Commended, C. F. Johnson; W. Walter; J. Judd.

Robins.—Prize, Master J. Bayden.

Blackbird.—Equal Prize, H. Vine; A. Raven, Norwood. Very Highly Commended, W. Newman; A. Isaacs, Prince's Street Leicester Square. Highly Commended, G. Plummer.

Thrush.—Equal Prize, J. Trusson, Lower Norwood; R. J. Baldwin, Northampton. Very Highly Commended, W. Newman; W. Walter; A. Isaacs. Highly Commended, H. Vine.

Starling.—Prize, J. Judd. Very Highly Commended, Mrs. Nickless; J. Judd. Highly Commended, F. Nickless, Westminster Road, London; Miss R. Nickless; C. Nickless.

Magpie.—Prize, A. Von Glehn, Sydenham. Very Highly Commended, G. Treacher. Highly Commended, J. Collins

Any other Variety of British Birds.—First, H. Hanley. Second, Mrs. La Touche. Very Highly Commended, R. Pruden Highly Commended, Mrs. La Louche; J. Pullen; W. Walter; H. Marshall; W. Williams, Nottingham.

BIRDS OF PASSAGE AND MIGRATORY BIRDS.

Blackcap.—Prize and Highly Commended, C. F. Johnson.

Nightingale.—Prize, T. Alderton, Woolwich. Highly Commended C. F. Johnson.

Siskin.—Prize, R. J Troske. Very Highly Commended. Mrs. La Touche; J. Judd. Highly Commended, J. Meredith; H. Vine; W. Price.

Titlark or Tree Pipit.—Prize, J. Judd. Very Highly Commended, W. Walter; H. Hanley. Highly Commended, J. Judd.

Any other Variety.—Prize W. Walter.

FOREIGN BIRDS.

Lemon or Orange-crested.—Prize, F. Schweiss.

Cockatoo, Leadbeater, or Rose-breasted.—First, A. Isaacs. Second J. C. Winn. Very Highly Commended, W. B. Bailey, Romford. Highly Commended, A. Isaacs.

Cockatoo any other Variety.—Prize, A. Isaacs. Very Highly Commended, J. Judd.

Grey Parrots.—First, C. Thompson, Upper Norwood. Second, C. W. Wass, Upper Norwood. Very Highly Commended, Messrs. Mitchells, Mile End Road, London; W. Heap; W. Waller, jun., Tabernacle Walk, Finsbury; J. Judd; W. B. Bailey. Highly Commended, E. Upton, Norwood.

Green or any other Variety of large Parrots Except Grey.—First, W. W. Westbrook (Turon). Second, A. Booker (Amazon). Third, W. B. Bailey. Very Highly Commended, A. Booker, (Duffrensis, West. Indies); A. Isaacs (Bulla Bulla). Highly Commended, W. Walter (Bulla Bulla).

Love Birds.—First, W. Walter. Extra, J. Judd. Very Highly Commended, A. Isaacs; J. Judd.

Austra lian Grass Parakeets.—Prize, J. Judd. Very Highly Commended, W. Price; W. Walter. Highly Commended, Miss H. Maunder; A. Isaacs.

Ring-necked or Bengal Parakeets.—Prize, Hon. F. Dutton, Piccadilly. Very Highly Commended, J. C. Winn. Highly Commended, Hon. F. Dutton; Miss H. Maunder. Commended, W. H. Wright.

King Parrots.—Prize, F. Marshall. Highly Commended, J. Rose, Norwich.

Rosebill Parakeets.—Prize, J. Judd. Very Highly Commended, J. Judd. Highly Commended, W. B. Bailey. Commended, W. Walter.

Red-Rump Parakeets.—Prize, J. Judd.

Cockateals.—Prize, J. Judd. Very Highly Commended, J. Meredith. Highly Commended, A. Isaacs.

Any Variety of Lory.—Equal, J. G. Chillingworth; J. Judd. Highly Commended, J. Judd.

Diamond Sparrows (Single).—Prize, J. Judd. Very Highly Commended, A. Isaacs. Highly Commended, Miss H. Maunder; W. Walter.

Coral-necked Sparrows. — Prize, W. Walter. Very Highly Commended and Highly Commended, Miss H. Maunder.

Java Sparrows.— Prize, A. Isaacs. Very Highly Commended, H. Vine; W. Walter. Highly Commended, Miss H. Maunder.

Nonpareils.—Prize, Miss H. Maunder. Very Highly Commended, W. Walter.

Indigo Blue Birds.—Prize, J. Judd. Highly Commended, W. B. Bailey.

Bishop Birds.—Prize, J. Judd. Commended, H. Hanley.

Zebra Waxbills.—Prize, W. Walter. Commended. J. Judd.

Orange-Checked Waxbills.—Prize, Miss H. Maunder.

Any other Variety of Waxbills.—Prize, W. Walter.

Virginian Nightingales.—Prize, W. Price. Commended, Miss H. Maunder; S. Burge.

Cardinals.—Prize, Miss H. Maunder. Commended, W. Walter.

Whidah Birds.—Prize, W. Walter.

Any other Variety of Foreign Birds.—First, A. Isaacs. Second, M. Nathan. Third, Miss H. Maunder. Highly Commended, W. Walter; A. Isaacs; W. B. Bailey. Commended, W. Walter; A. W. Booker; A. Isaacs; M. Nathan.

Judges.—*Canaries*: Mr. G. J. Barnesby, Mr. T. Moore, and Mr. A. Wilmore. *British and Foreign Birds*: Mr. W. Goodwin.

VENTILATING INCUBATORS, AND INCUBATING TEMPERATURES.

As that which Mr. Schroder states in the number published January 31st is incorrect and likely to mislead, allow me space for a few remarks. He says that his incubator is the only one constructed to supply the eggs with constant ventilation. He has fallen into error. My incubator allows, and always has allowed, for a continual supply of fresh air to the eggs; and indeed I can hardly think that any one who knows anything of hatching could omit so important a part in the construction of an incubator as that which provides for supplying the eggs with vital air. I have an incubator by Cantelo, and the eggs in that are subjected to constant ventilation—I think too much, as, although it is certain they require some, it is as certain they require but little, eggs when hatching in the natural way being entirely covered by the hen's body, and receiving very little air except when she is away from her nest.

It is not my wish to detract from the merits of any incubator or to extol my own; but as "Investigator," a few weeks since, questioned the possibility of keeping an incubator with a wooden case of an equal temperature, I will say that mine is constructed of wood for the very reason of its quality of resisting external temperature. But I do not trust to wood alone: to make assurance doubly sure I protect it internally with hair felting, causing the temperature to keep regular with very ordinary attention, as the following facts will prove. Last night at ten o'clock I left the temperature at 102°, and found it this morning at eight o'clock exactly the same; and on the previous night I left it at 100°, and found it 99°, and it was very regular at from 102° to 105° during both days.

Three weeks ago. when the temperature out of doors was from 20° to 25° below freezing, I worked the incubator a few days for experiment. I left it a 11 P.M. at 102°, and found it at 8 A.M. at 100°; and although the temperature out of doors increased several degrees by noon, that of the incubator fell a couple of degrees, but this was on account of the pressure being taken off the mains. The next night I left the temperature at 100°, found it 98°, attended to the gas, and at noon it had reached 101°. The incubator is now working in a small outhouse where there is no warmth except that caused by it. With all deference to "Investigator," I must say that it will take much to shake my faith in wood *versus* metal, for the outer construction of an incubator.

With regard to the temperature an egg will bear, "E. S." stated on January 8th, that a temperature of 110° did not kill, although the eggs were subjected to it for a whole night. I say that in the first week, although dangerous, probably a higher temperature than 110° would not kill; but towards the end of the third week 110° continued all night would be certain death. Eggs require less heat during the last week of hatching. Some aver they require more heat, but it is a mistake: a hen is not so warm when wasted by sitting as when she commences to sit.

It is quite needless to turn the eggs twice a-day, and although I consider it advisable to do so once a-day, I can upset the theory of turning them at all during the whole time.

Without having the presumption to state, as Mr. Schröder virtually does in his prospectus, that every incubator except his is a bad one, I will presume to say that if mine, as now

constructed, will not answer well, if properly worked, I am quite sure no incubator can; it has the advantages of being very compact, and, being a handsome piece of furniture, it may be kept working in any out-of-the-way corner of a room, and, if taken care of, twenty years will not wear it out. When at Birmingham during the late Show I was complimented by all who examined it, and had the pleasure of taking many orders. —John Brindley.

NEW PUBLICATION.

The Instantaneous Reference for Poultry, Pigeons, and Rabbits. By David P. Gooding, Tower Hill, Ipswich.

We are disposed to think gratefully of those who undertake to lessen our labours. Thus we recollect seeing in a nursery a large sheet, very like that with which we have to do, which started well. It said, "In the event of accident or illness send for a medical man, but if none be at hand, use the following remedies;" and then there were instructions for burns, sprains, dislocations, fractures, and all the other ills that flesh is heir to. So again the industrious compiler of "Europe at a Glance," who gives the population, revenue, expenditure, army, and navy, of every country at a glance, is no mean benefactor to those who need such knowledge, and has much to do with the reputation for talent and industry gained by many men by their readiness at handling millions, and comparing great things. We think a good history of any country, "abridged for the use of schools," is a boon, and dispenses with the necessity for reading much that occurred years ago, and is not very important now.

Mr. Gooding seems to be ambitious to rank among the benefactors of the poultry world, and has abridged the poultry books, condensing their information. He is bold in his labours, inasmuch as he challenges the best judges to impugn his correctness in any particular. We believe we could point out inaccuracies, but we would rather speak of the whole as a useful sheet and guide for the young amateur, enabling him at a glance and in a minute to see the merits or deficiencies of his pets. He goes well into Pigeons; but we could not refrain a smile when at the end of the Rabbits we find the "Welsh Rabbit." It is said to weigh from 8 to 12 lbs.; we confess we do not know it. We think Mr. Gooding might give us some instructions about food, as to quantity and quality; also a few hints indicating the necessary treatment of fowls in health and disease. Until we obtain all this, we wish him a good sale for his present sheet.

AN UNLUCKY APIARY.

Having been a bee-keeper on a small scale for about five years without taking much trouble to comprehend my little labourers intimately, I last year thought I would make a grand effort to become a scientific apiarian.

In February last I became the purchaser of twenty stocks in a miscellaneous collection of hives (making with my original ones twenty-three), some strong in bees, but, apparently, all weak in honey. I set to work at once, and built a commodious bee-house, dry, light, and airy, and ensconced my hives therein. My next move was to make half a dozen Woodbury hives, to which I thought I could transfer some of the weak stocks. The hives made, now came the trial of driving. Following Mr. Woodbury's directions, I succeeded very well; in most instances I saw the queen in her transit. I made no failures; sometimes I found the bees very obstinate, but as I did not intend to be beaten, I took out the combs, and brushed the bees off. The combs were then fixed into the frames with wires, &c., and left for their proprietors to repair, a bottle of syrup being placed on the top of each hive, and all made snug.

Now came the first hitch, the syrup was of but little attraction, and the bees made no efforts to fix the combs for some weeks, and then, after making good the damage, some deserted the hives entirely, while others did not attempt to take in the food, and died eventually of starvation. My other hives, which I had not meddled with, fared no better; and although I liberally supplied the syrup, by May my twenty-three stocks were reduced to eleven. Not discouraged, I trusted to repair damages by good manipulation in the way of artificial swarming. As soon as the bees began to hang out I proceeded to drive the artificial swarms. Here again, following the "Devonshire Bee-keeper's" instructions, I found no difficulty, and soon became so expert that I could dispense with the close junctions of the hives, and drive openly. My bee-house soon became populous again, containing then about twenty-five hives; but things did not yet go smoothly, the hives were constantly being plundered and deserted; one hive especially, a Neighbour's cottage, I stocked four times, and still have it empty. On some of the hives, apparently strong, I placed supers, but only one supplied about 5 lbs. of honey.

July now came, and a month's absence occasioned by other avocations, coupled with a severe illness, caused my bees to be left to their own resources, and on my next examination I found five hives minus their inhabitants. Such desertions continued till late in the autumn, when the result of the season was that I was left with fourteen stocks, besides three which I had disposed of, and 19 lbs. of honey; and not more than a third of my stocks had a full store. This was the more annoying to me, as I had been trying to impress the merits of modern bee-keeping on some of my neighbours of the old school, and when I find that a cottager adjacent with about eight stocks has on the fire-and-brimstone principle secured upwards of 100 lbs. of honey and an increase of bees, it seems good evidence against scientific bee-keeping.

However, I think *Nil desperandum* a very good motto, and I do not surrender yet, so have begun to prepare for another campaign. Last December I purchased four hives for a trifle, strong in bees and honey, but with all the combs broken loose, and to their last owner unmanagable; some person had, apparently from malice, tried to destroy the whole. The day I received them was raw, cold, and foggy, but as the case would not admit of delay, I drove them all into straw hives full of empty combs, and fed them with the bottle, to which they took kindly; their old combs, mostly full of honey, I intend fixing into Woodbury frames, and then to re-transfer the bees. I should have domiciled them in these hives at once, but had none ready.

My bee-house now contains eighteen stocks, twelve of which by the spring will be in Woodbury hives, and I intend another fair trial, trusting with experience gained to be more successful this year; but I should like to ask some of your more experienced apiarians if they can point out any probable cause of the wholesale desertions from my hives. I may say that all my straw hives were in good condition, and none new. The new wooden ones were made of inch deal, old stuff, so that there should be little smell of turpentine.

In conclusion I may say that two years ago I should never have thought it possible that I could have managed to manipulate my bees in the manner I have. I have come to the conclusion that the great desiderata are courage and coolness. As an instance I may say that my little son, eight years old, has several times, perfectly unprotected, assisted me when driving by holding the empty hive, and has come to no harm thereby.—Nil Desperandum.

[This is a good illustration of the mistake committed by endeavouring to "run before you are able to walk." Had you felt your way, and advanced cautiously step by step, you would have saved yourself much trouble and disappointment. The cause of your first failure is evident enough; you attempted the transfer into frame hives too early in the season, before the bees were sufficiently numerous to set to work with spirit in the reparation of damages, and whilst the weather was not only so chilly as to render it difficult for them to do so, but actually so cold as to compel some of them to starve through inability to appropriate the contents of their bottle-feeders. The causes of the subsequent failures and of the wholesale desertion of your hives are not so apparent from your description, and might probably remain obscure, even if you entered into more minute particulars; yet we have no doubt whatever that they arose from mistakes attributable to inexperience, which would not have been committed by an accomplished apiarian, and which future practice will enable you to avoid. Such experience as yours says really nothing whatever against truly "scientific" bee-keeping, but merely proves that, like any other science, it cannot be mastered all at once without difficulty.]

Pollen-gathering at Christmas.—I saw pollen carried into one of my hives on Christmas-day, and many bees were, doubtless, busy in other hives; but the diminution of stores has been great. I may add that after the recent frost on January 6th the bees were busy carrying out young dead bees in every stage. The thermometer fell here to 10° Fahr. Another matter of importance is to warn apiarians to see that their bees are well supplied with food. The consumption of honey has been very great up to January 1st.—B. & W.

THE FOOD OF QUEENS.

I am not aware that the food of the queen in her larva state has received any more definite description than that it is "a peculiar substance." It being absolutely necessary that all experimentalists should understand as far as possible all matters with which they have to deal, I have been induced carefully to examine the food in all the royal cells at my disposal. These examinations proved to me that this white substance was prepared within the hive, and that it consisted of larvæ torn to pieces, and intermixed with honey. Its being an animal substance accounts for the queen arriving at maturity sooner than the workers.

To prove the above I have had some beat-outs rearing queens whilst confined in a dark room from the time the egg was deposited until the queen was hatched.—North.

IMPORTANCE OF THE BEE IN THE ECONOMY OF NATURE.

A few years ago a tropical papilionaceous plant was imported to the Jardin des Plantes, Paris, for the purpose of acclimatisation. (The clover, the pea, the bean and the locust tree all belong to the same natural order.) To the great delight of the gardeners the tree grew and blossomed; but as it belonged to a species of which each plant produces only either male or female blossoms, and this one bore only female blossoms, there was nothing to be admired on this tree besides the blossoms. Thus a few years passed away, when the tree, to the great astonishment of its admirers, bore fruit also. This would have been a miracle, were the opinion correct that bees are not instrumental in the fertilisation of plants. But the *savans* of the Jardin des Plantes were not inclined to believe in such miracles. They had come to the incontrovertible conclusion that there must be growing in Paris a male specimen of this plant; but they could not see clearly how the pollen had reached the female blossoms of the tree in the Jardin des Plantes. They made every possible effort to discover at least the location of the male specimen. Every garden of the neighbourhood was searched, inquiries set on foot in the papers, but nothing could be discovered. At last the director of the Jardin des Plantes had a lucky idea. He asked the police to assist him in finding this hidden son of the vegetable kingdom. Every policeman was provided with a description of the plant, and now commenced the most harmless search which probably ever took place in Paris. The police proved themselves worthy of their reputation. At the distance of about half an hour's walk the only male specimen of this plant in Paris was found in the garden of a rich gentleman. That the tree in the Jardin des Plants had in all probability been fertilised from this one was made plain by the statement of the proprietor that his plant had blossomed this year for the first time. In order to ascertain how impregnation had taken place, the tree was watched closely next spring in blossoming time, and nothing was seen but bees flying to and fro among the blossoms. They had here covered themselves with the pollen, had flown thence to the Jardin des Plantes, and thus effected fertilisation. Some might be inclined to say that "perhaps the wind did it." The wind certainly does its part towards the fertilisation of plants, especially if they stand in close masses like rye, wheat, corn, &c., but in this instance it would have been impossible for the wind to carry the small amount of pollen over intervening gardens and houses, and to communicate it to the female blossoms of the tree in the Jardin des Plantes.—(*American Bee Gazette.*)

OUR LETTER BOX.

Grey Dorkings and Brahma Pootras (*Constant Reader of Our Journal*).—We do not advise you to mix your birds, nor do we think it should be troublesome to keep them separate. As the Dorkings must have a run, and as the Brahmas can dispense with it, we advise you to let the Dorkings out almost always and the Brahmas now and then. Let the Dorkings go out every day, and the Brahmas every other day, from daybreak to mid-day. We do so ourselves, and the birds become so used to it that there is not the least trouble in the process. You do not want the Dorking cocks for change of blood, but you want them because twenty pullets are too many to run with one cock. You have had neighbour's fare as regards eggs. No one has had any, but your pullets ought to lay now.

Mortality among Fowls (*J. P.*).—We have heard of no such disease as you mention. There will always be mortality during very hard frost, and still more when the earth is for a long time covered with snow. We believe the birds which died in numbers must have eaten some violent poison, or Ducks, Geese, and fowls would not have shared the same fate.

Golden-pencilled Hamburgh Cock's Tail (*Novice*).—The tail of a Golden-pencilled Hamburgh cock is an important part of his plumage, and it is therefore necessary it should be entire. The most important feathers are the sickles, because they require to be accurately bronzed on their whole length. If, then, one is missing, it always gives the idea that it has been removed for some fault or shortcoming. They should be above the other feathers, and, describing a graceful curve, they should hang below them.

Newport Poultry Show (*Hamburgh*).—It is not a subject for publication. Write to the Traffic Manager of the railway for information.

Proportion of Cocks to Hens (*Firefly*).—One cock is not sufficient for twenty hens. If you have two they will fight, but when it is known which is the master the beaten bird will take some hens and go off with them. If, however, you object to this, we advise you to let one run with the hens in the morning, the other in the afternoon. This may and will answer, but not so effectually as if both were with the hens. It is very important both should be with them when they leave the house in the morning.

Ears of Lop-eared Rabbits (*A Rabbit Fancier*).—They are often exhibited with ears 23 inches long from tip to tip. If you send seven postage stamps with your direction you can have "The Rabbit Book" free by post. It contains much that you ought to know.

Aged Birds—Cross-breeding (*C. Ellis*).—We do not perceive that your statement alters what we stated. It is certain that after three years old hens become more and more defective as layers. As for fowls cross-bred between Houdans and Spanish being good sitters, your experience is an exception to the rule.

Confined Space (*J. R. Beyton*).—A space 60 feet by 25 is a confined space for poultry. Brahma Pootras or Dark Cochin-Chinas would be the preferable kind to keep in it.

Profitable Poultry-keeping (*Mrs. H.*).—If properly managed they can be kept profitably.

Poultry Food (*D. J.*).—Give the bruised oats, but omit the maize and buckwheat, and instead of barley give a little barleymeal once daily. The scraps, &c., are quite admissible. In your confined space the great danger to fowls is over-fatness.

Cochin-China Cock Paralysed (*E. B.*)—The giddiness, "floundering about," and loss of the use of one leg, indicate that a blood-vessel has ruptured on the brain. The bird probably is over-fat. Perfect quietude and nourishing diet given sparingly, and a little at a time, will give him the best chance of recovery.

Book about Game Cocks (*C. Francis*).—Cooper's volume on this subject has long been out of print, and can only be met with at second-hand booksellers.

Cork Poultry Show.—We are informed that Mr. Cooper took first prize in White-crested Polands, not Mr. Williams.

Rabbit-judging at Halifax (*J. Taylor*).—All that you say may be true, and yet the Judge might be justified in disqualifying your Rabbit on account of its defective eye. We cannot publish vague suspicions.

Rabbits (*Himalayan*).—If no age is specified in the schedule, we see no reason why young and old may not be exhibited in the same class. In fact, specifying ages induces deception.

Foul Brood in a Purchased Stock (*J. B., Bracken Hill*).—We regret to say that the bit of comb which accompanied your letter contained unmistakeable foul brood. It is very unfortunate that you should have transferred any of the combs to other stocks, since it is more than probable that they also will become diseased. As a considerable time may elapse before this point can be determined with certainty, we should advise their being isolated from all others as far as possible, and on no account should any of their combs be interchanged with or introduced into other hives. It will, we think, be better to return the defunct hive with its remaining contents to the respectable firm from whom you obtained it, and ask them to refund the money, in preference to running the risk of receiving another colony from an infected apiary. The fact of these so-called Ligurian bees turning out to be hybrids sufficiently accounts for their irascibility.

Boxes for Hives (*B.*).—Your boxes, 16 inches in diameter and 7 inches deep, are not too large for stock hives, but a hard wood like ash being a good conductor of heat, will require extra protection in winter. As the hives are likely to be sent to the moors, we should put sticks across the interior in order to support the combs. We prefer side slits to a central aperture for supering.

Wooden-topped Straw Hives (*A. K. H., Westhorpe*).—John Hockins, Esq., of Bathampton, Bath, would be glad to communicate with you on the above subject.

Birds for an Aviary (*R. G.*).—About twenty-six birds might be conveniently kept in an aviary 12 feet long, 9 feet wide, and 7 feet high. Those requiring the same mixture of food are the following:—One pair of Undulated Paraquets, one pair of Red-faced Love Birds, one pair of Whydah Birds, two pairs of Grenadier Buntings, two pairs of Waxbills, one pair of Cardinals, one pair of Red-headed Cardinals, one pair of Virginian Nightingales, one pair of Glossy Thrushes, and two pairs of Weaver Birds. This time of the year is best to purchase them, as they will be in good condition by the summer. For food give canary seed, millet, hemp, a few crumbs of bread, a little chopped meat, mealworms, and other insects, green food, such as chickweed, watercress, and lettuce; water and gravel of course.

Gold Fish—Pairing Canaries (*W. H. H.*).—The white fungus on gold fish is a parasitic disease to which they are subject when confined in small ponds, and which is difficult to cure. Wash them over with a weak mixture of common salt and water (4 ozs. to a gallon of water). We have known several instances where that has proved successful. The best time for pairing Canaries for breeding is about the middle or end of March, according to the mildness of the season. Separate breeding cages are far preferable to a room; the young birds become much stronger and more healthy.

POULTRY MARKET.—February 13.

Our Game season is over, and we may now soon look for a larger consumption of poultry. Judging from our own experience, we expect a poor supply of young poultry for a time, and consequent high prices. We believe the stock of young chickens to be unusually small. The Game season has been an average one as regards Pheasants. Partridges were very scarce till the snow came; that is their time of danger, and thousands were killed. Hares have been scarce throughout. Grouse and Woodcocks have been sent up in numbers far exceeding any other year.

WEEKLY CALENDAR.

From observations taken near London during the last forty years, the average day temperature of the week is 47.0°; and its night temperature 32.5°. The greatest heat was 58°, on the 21st, 1845 and 1859; and the lowest cold 13°, on the 24th, 1850. The greatest fall of rain was 0.92 inch. N.B.—The Calendar contains the names of plants flowering in the greenhouse.

VERBENA CULTURE.

FOR repotting and preparing the store plants of Verbenas for propagation the present is a favourable time. One of the most important points to be attended to in increasing a stock of Verbenas, and that most likely to insure success, is to have the plants in a good healthy state of growth before taking the cuttings from them. If a sickly cutting is employed for propagation there is every probability that the plant produced from it will be sickly, unless it is grown under favourable circumstances; even then it will not assume a healthy character like a plant that has been propagated from a healthy stock, and it is more liable to the attacks of several kinds of insects. If the cutting is taken from a plant in perfect health it will strike in half the time that is generally necessary to strike one that has been taken from an unhealthy plant.

My stock plants are always struck and kept through the winter in small 60-sized pots. The cuttings are put in early in September in a cold frame, and plunged in cocoa-nut refuse; a two-light box is generally used for this purpose, and the tops of the cuttings, when the pots are plunged, are within an inch or two of the glass. When there is no wind or sun the lights are taken off; also at night, if there is a probability of a heavy dew occurring, and no wind is apprehended. If there is a gentle shower during the day the lights are also removed, the object being to keep the cuttings from flagging. If they are carefully treated in this way few will fail in striking. I generally put eight cuttings in each pot. As soon as the cuttings are rooted they will begin to grow, when their tops should be immediately pinched out, and when they have well filled the pots with roots, they should be removed to another frame, and more room should be given to prevent their drawing up weakly. They must still be kept as near the glass as possible, and on no account must they be allowed to suffer from want of water. On the first appearance of green fly no time must be lost in fumigating, and as soon as each shoot has made three pairs of leaves it should be stopped. This treatment should be carried out all through the winter months, and a fine stock of handsome bushy plants will be the reward for the extra care.

The best place to keep the plants through the winter is a front shelf in a cool greenhouse, where they can have the benefit of light and air; they must be kept as cool as possible from October to February, when they should be repotted and placed in heat, where they will soon produce large numbers of shoots in the very best condition for propagating.

Having described in as few words as possible the proper winter treatment for the Verbena, I will now state the care the plants and cuttings receive from this time till they are planted out in May or June.

The soil most suitable is a good turfy loam mixed with a small portion of sand and leaf soil; it should be in a good healthy state, neither too wet nor too dry, and instead of rubbing it through a sieve it is better to pull the sod to pieces with the hand. The plants should also be in a nice state at the time, neither too wet nor too dry; if the old soil in which the plants have been growing through the winter and the new soil to be used now are as nearly as possible in the same condition as regards moisture, there will be no necessity for watering the plants soon after potting; if they be slightly sprinkled overhead with the syringe once or twice during the day it will be sufficient to keep them from flagging. This treatment will cause the roots to strike into the new soil much more quickly. I consider it a very bad practice to deluge a plant of any kind with water directly after potting, and for this reason—the soil often becomes sour in consequence, and the plant will not so readily strike root into it; but, on the other hand, if both soils are in a proper state of moisture at the time of potting, root-action will immediately commence, and by the time the plant will actually want water at the roots these will have reached the sides of the pot, when it may be copiously supplied with water if the weather should be bright or the temperature high. The pots I use at this time are 48's; these should be well drained. After turning the plants out of the small 60-pots the first proceeding should be to scrape the drainage away from the roots; then squeeze the ball gently in the hand to loosen the soil from the roots. If the ball is then shaken a little some of the small particles of worn-out soil will easily fall away. The ball should next be gradually opened out; this is done by making a hole through the centre of it, and gently pulling it out from the centre with the fingers. A portion of the new soil can by this means be placed in the centre of the old mass of roots and soil. This offers fresh food to the roots on every side, and there is no fear of the old ball becoming dry owing to the water passing through the loose soil at the sides, which is often the case where the roots are very much matted together, and when the precaution is not taken to properly disentangle them. Before pressing the soil firmly about the roots the pot should be tapped several times on the bench; this will settle the soil well about them. The operation may then be completed by firmly pressing the soil round the sides of the pot, and also in the centre of the ball.

After the plants have been potted, they should be placed in a temperature of 65° or 70°, and as near the glass as possible, to prevent their drawing up weakly. Here they will produce abundance of fine healthy shoots for cuttings; two or three crops may be taken from them weekly if proper care be exercised in taking the cuttings. A good sharp pair of scissors is the best instrument for this purpose; with such you may cut the shoot out just above the next pair of leaves. The space from the base of the cutting to its first pair of leaves will be long enough to insert in the soil, and in putting in the cuttings these leaves should not be covered

with the sand, for the eye at the base of the leaf is often injured when this is the case, and the loss of two good shoots is the consequence. The eye next to that part whence the cutting was taken will be the first to break. In taking the next crop of cuttings off care should be taken not to cut them off close to the stem, but to leave one pair of leaves below the cut. By this means the plant is extended in its growth, and the number of cuttings very much increased. The plant also matures the leaves that are left on it; these prevent its suffering injury by the constant cropping of its young shoots, and regulate the reciprocal action of root and branch, which enables the plant to produce a vast number of cuttings without suffering any ill effects.

As soon as the plants have well filled their pots with roots they may be watered with liquid manure three or four times every week; this will cause them to produce fine healthy cuttings. The same plants may be worked at this rate from February to May, and will not show any signs of exhaustion if they are liberally supplied with liquid manure; this, however, should be applied in a clear state. Guano I find the most suitable for them.

It will be seen by the above that it is not necessary to keep a large number of plants of each kind of Verbena through the winter. Six good plants of a kind will be enough to work a stock of two thousand plants from. It is a good plan to strike in May a small cutting-potful of any choice kind that will not strike readily in the autumn. If the plants are potted off in small pots, plunged in some place partially shaded from the sun, kept pinched in rather closely, and then shaken out and potted in large 60-pots towards the end of July, they will make fine stock plants, and may be easily kept through the winter. This is, perhaps, the safest way, for sometimes it is difficult to obtain good cuttings in the autumn.—J. Wills.

VINE AND OTHER WALL-TREE BORDERS.

Having read the different articles, by Mr. Wills and others, which have appeared lately on making Vine borders, I have been induced to offer a few remarks on the subject, and on fruit-tree borders generally.

I must confess I was somewhat surprised when I read Mr. Wills's article, and found him advocating borders 5 feet deep (that depth being so much greater than has been recommended by some of our best Grape-growers, Mr. Thomson and others), and at a time when there has been so much said in favour of shallow borders for fruit trees generally. Now, I do not assert that Mr. Wills is wrong, for I am one of those who believe that good Grapes can be grown in many ways; but I cannot see clearly the great use of supplying roots with food 5 feet from the surface. I am in favour of borders of a medium depth, say 2½ or 3 feet for Vines, and 2 feet for most other wall trees. I quite agree with "Vitis" as regards top-dressings; I have adopted them for many years, and I think they cannot be too highly recommended. To attract roots to the surface by feeding them cannot fail to produce the most favourable results, and there will be but little danger of their going down into bad soil. I am no great advocate for concrete at the bottom of Vine or other borders; there may be some cases where it would be necessary, but I have never used it. I think if there is water below it should be carried off by deep draining; but in all cases I would use drainage for Vine borders, whether inside or outside.

The drainage I use for Vines is formed as follows:—7 or 8 inches of broken brick or other rubble, 1 inch of fine gravel, with the dust taken out, and about 1½ inch of coal ashes made smooth and firm; then the compost, consisting of such materials as often recommended—namely, good turfy loam, farmyard manure, lime rubbish, bones, and charcoal.

I will now make a few remarks about stratified borders. I think Mr. Wills's two-inch layers of bones, &c., likely to be useful. I once made some borders on the stratified system, not for Vines, but wall-fruit trees of all kinds excepting Pears. In the year 1848 I took charge of a garden where the walls had to be refurnished as soon as possible. The soil of the garden was very unfavourable to fruit trees generally, and having a limited quantity of good loam at command I adopted a system once recommended by Mr. Errington. Stations, 8 feet square, were marked out for the trees, and the soil excavated to the depth of 30 inches; then the drainage, the same as described for Vines, was put in, and the station filled in to within 6 inches of the top with loam and fresh stable-litter in alternate layers, three of each. The tree was then put in its position, a layer of leaf mould 5 or 6 inches deep placed over the roots, and over this a little loam. These stations were kept covered with stable-litter during the summer, and received a surface-dressing of old hotbed manure or rotten leaves annually, or when it was thought necessary, and in the case of very dry weather a little water was given. The trees grew very fast, and as the roots were continually cut on the outside of the 8 feet, they soon became very fruitful.

I attribute a great part of the success to the quantity of rotten leaves put in with the trees and to the surface-dressings. The object in using the stable-litter in layers with the loam was to keep the latter a little more open, as nearly all the fibre was decomposed, it having been cut from a pasture some years previously.

In the autumn of 1861 all these fine trees had to be removed to a new garden, and when taken up their roots were in a most healthy condition, and only in a few instances did we find any roots through the drainage, but the great bulk of them was near the surface. When spread out on the new border their appearance was excellent, especially in the case of the Cherries, for we could lay them in almost as regularly as the branches.

The site of the new garden was an old pasture, and the borders were formed as follows:—The sods were cut about 6 inches thick, and taken at once to form that portion of the border intended to be entirely devoted to the trees, which was 6 feet wide and 2 feet deep, without artificial drainage, excepting for Peaches, the subsoil being chalk. The sods were built up to the height of 18 inches or a little more; the last layer chopped and made smooth; it was then ready for the trees, which were planted with rotten leaves as before. I used one cartload to each tree. In this way I planted about eighty trees by the 20th of December; then the whole of the six-feet border was covered to the depth of 8 or 10 inches with stable-litter. In the following season the greater part of the trees set plenty of fruit; I thinned them out to about half a crop, and they were very fine, and of excellent flavour. The Peaches were the finest I ever grew out of doors.—W. R.

JUNIPERUS RECURVA.

I observe in the Journal of the 25th of December, page 480, that Mr. J. Sharp wishes for information respecting Juniperus recurva.

In cool soils it is not liable to the attacks of the red spider, and there it is a very graceful and beautiful drooping plant; but it becomes so rusty and unhealthy in dry, warm soils, as to be useless. For this I know of no remedy, as both it and Juniperus recurva densa require a cool, shady situation, owing to their liability to red spider. I would replace it with Juniperus virginiana, virginiana pendula viridis, or with Juniperus phœnicea.—F. Flitton.

HARDINESS OF FARFUGIUM GRANDE.

I have long entertained the belief that this plant is perfectly hardy.

On the 23rd of February, 1857, a young plant of it was planted in a south border in a garden in Warwickshire, in which I was then engaged. There was some sharp weather afterwards, but the plant was not injured. In 1865, having a specimen under my charge that was growing rather too large for the conservatory, I decided on placing it out of doors to test its hardiness. The position assigned to it was an angle formed by the end of the stove and a wall dividing the frame-ground from the kitchen garden, the aspect of which was south. The plant, in a pot 18 inches deep and 21 inches in diameter, was placed in this position, and remained there until last week. The winter of 1865-6, was very mild here; the lowest point registered was 23°, until the 1st of March, when the thermometer stood at 11°, yet the Farfugium was uninjured although quite exposed; and in the summer of last year it was a fine specimen both in size and colour, being nearly 5 feet in diameter and beautifully blotched.

This year we were destined to experience a more severe winter. The year opened with the thermometer at 11°. This was followed by two days of similar intensity, one at 12° and one at 9°. The Farfugium all this time was perfectly exposed without covering of any kind, and must have been frozen quite through the ball. I thought this more than enough, and that more unkindness would be wilful murder, so after a slight

thaw I had some litter thrown over it. After this the frost was as sharp as ever. Last week I turned the plant out of its pot, and after deciding to use it for a sub-tropical border this summer, I divided it into sixty good solid crowns, all of which are showing life, and I have no doubt will make fine plants by next June.

In the Farfugium, then, we have a variegated-foliaged plant of no mean merit and quite hardy, therefore of much value to the gardener; for who amongst us does not feel the want of plants which will prove effective in the summer and yet not occupy our valuable space in the spring? One remark about culture. Use fresh-cut loam with plenty of sand. Rich soils and manure water turn the foliage green.—Geo. Boyes, *Barley Thorpe Gardens, Rutland.*

VISITS TO GARDENS PUBLIC AND PRIVATE

The Denbies, Dorking, the Seat of Mrs. Cubitt.

In visiting many fine places one has the feeling oftentimes that everything has been sacrificed to show, and that the wishes of the proprietor have given way to the exigencies of appearance—that the gardens are show places, but nothing more, and that the owner has very little enjoyment in them. Certainly this is not the case at the Denbies, for one would at once say, The owner of this place loves flowers and plants, and, what is more than that, has taken every means for the enjoyment of that love in the most agreeable way possible; and although my visit was a very hurried one, quite insufficient to do justice to the admirable manner in which every department of the garden is carried on under the able management of Mr. Drewett, I yet saw enough to convince me that in few places is there more real enjoyment for the owner than here.

The valley of the Mole, in which Dorking is situated, affords to the lover of genuine English scenery a charming sample of it, and that in the immediate neighbourhood of our great metropolis. An hour from London brings you into the heart of it, and there Nature and Art combined have done their best to gratify all lovers of rich, rural scenery. Dorking itself is a classic name to the English horticulturist, for Mr. Ivery, of that place, by the zeal and skill with which he and his foreman Mr. Appleby have carried on the cultivation and production of Azaleas and British Ferns, has made it so. When I paid my visit there in August the time for both was well-nigh over. Azaleas were of course out of doors, and Ferns were past their prime. However, I saw many of the newer varieties, such as Polystichum angulare parvissimum, which bears the same relation to the species that Lastrea Filix-mas crispa does to Lastrea Filix-mas. Then Polystichum angulare Wakeleyanum and P. aculeatum acrocladon were very interesting, the latter being the only one of this species which is tasselled. Of the Lady Ferns, Elworthii, Vernoniæ, Victoriæ, Iveryanum, and Frizelliæ nanum were all beautiful; but, in truth, the variations of these Ferns are endless, and one must only allude to them in the hope that the gratification that all lovers of Ferns can have at Dorking may be more sought after. There is always something new there, and what is not new is very admirable, the manner in which these Ferns are grown; their verdure and beauty exciting quite as much interest as if they were covered with brilliant flowers.

Having strolled through Messrs. Ivery's grounds, I then made my way up the hill on the opposite side of the valley, under the guidance of Mr. Appleby, to the Denbies, a place of which I had often heard, and which I had long been anxious to see. I need hardly say, what every one knows too well, that last season was about as bad a one as the lovers of gardening have ever had to contend with; nevertheless there was very much to see and admire. The situation of the house is charming—on the very summit of the hill, commanding a lovely view of both sides of the valley; on the one side enabling you to see far into Kent, and on the other away over Guildford, &c. It is also beautifully surrounded by fine trees, and in one part of the grounds there is the most lovely fernery that I have for a long while seen, the plants growing in the greatest luxuriance in the most natural way possible, and comprising some of the best of the many beautiful varieties of British Ferns, which are now so well known. Round the house—and this I look upon as the distinguishing feature of the place—runs a glass arcade 400 yards in length. You can enter into it through the conservatory from the dwelling-house, and not only enjoy an extended promenade in all weathers, in that which is truly a winter garden, but from it various plant-houses branch off, so that you can, without having to go out of doors, revel in all the beauties so liberally provided here. This arcade is literally covered with charming creepers of all kinds; Lapageria rosea, Escallonia rubra, Abelia floribunda, Plantago capensis, Banksian Roses, Habrothamnus fasciculatus, Cobæa scandens variegata, Gloire de Dijon Rose, the lovely Tacsonia Van-Volxemii, Bougainvillæa speciosa, Fuchsias, and a host of other plants covering the walls and roof. The Bougainvillæa is planted in a large slate box resting on the flues that warm one of the stoves; it is then brought out into an intermediate-house, which forms part of the arcade, and there produces its lovely bracts in great abundance. The Tacsonia deserves all the praise it has received, and nothing can be more lovely than those crimson parachutes suspended from the roof of the house. This is, doubtless, the way to see it in perfection, and from the manner of its growth here there does not seem to be any difficulty in its cultivation. In one of the houses branching off from the arcade there was a nice collection of fine-foliaged plants, and, which one does not often see in a private establishment, a very good collection of the plants of commerce, deeply interesting and instructive. The conservatory close to the house was, of course, very gay, Tacsonias covering a large portion of the roof; while on the walls at various heights were placed iron baskets with flowering plants.

Mr. Drewett is well known for the skill with which he cultivates Grapes, and his bunches, especially those of Muscats, have carried off many a prize. These were very fine, and I noticed that he had an air-chamber underneath the roots; but of Grape-growing it is hardly necessary for me to make remarks, so much has of late appeared on the subject in the pages of this Journal.

As I have already remarked, the season was most unfavourable for bedding-out plants; but there was evidence enough to show me that the Nosegay Pelargoniums do not endure the wet any better than the Zonale varieties, and that two bedding plants, about which there has been much dispute, do really deserve, in certain situations at least, all that can be said in their praise: one is Iresine Herbstii, the other Viola cornuta. The former, I dare say, is doubtful on wet soil and damp situations; but in dry places, such as the Denbies, it is beautiful, especially in the latter part of the season. Amaranthus is there "done for," Coleus shabby, but the Iresine charming. As to Viola cornuta, for a greyish blue border—an edging, for instance, for a bed of Mrs. Pollock, nothing can be more chaste; it continues, too, in flower for so long a period, some of it planted here having been successively in bloom until May. Amongst hints obtained was one of filling in a bed of Bijou, which is apt to be somewhat "leggy," with Cerastium tomentosum. In front of the greenhouses a capital border had been made of Dahlia Zelinda, Alba Multiflora, and Crystal Palace Scarlet; and in a season like the last the Dahlia, which seems to defy wet, was especially valuable.

Brief as the notice of my very hurried visit is, I feel it must not be closed without a reference to the exceeding care and attention bestowed by the owner, and seconded ably and heartily by Mr. Drewett, on the young men employed in the garden. A more comfortable arrangement than that provided for them cannot be imagined. Airy dormitories; good, clean, comfortable beds; places for their clothes; a library for them to read in, and means for cooking their food,—all these are as liberally provided for them as if they were the inmates of the house. Of what immense moral benefit this is none can better tell than those who, like myself, know what the young gardener often has to put up with—an untidy room in a house with a large family, where there is no quiet, and his only resource the public house and the demoralising influences of pot companions. All honour to those, then, who, like Mrs. Cubitt, believe that our influence for good or evil is sure to tell. Happy they who feel a pleasure in making it tell for good, and like mercy itself,

> "It is twice blessed—
> It blesseth him that gives and him that takes."

And I feel sure that in the interest which those employed feel in their employer such outlay is amply repaid. May many more follow the example.—D., *Deal.*

Edging for Garden Walks.—Let me recommend for this purpose paving-stones put down lengthwise. I tried this plan in Devonshire, and here in Warwickshire. Such an edging

looks well, is most durable, keeps its place, and is very inexpensive.—B. W. Stannus.

POTATOES.

I always read the Potato articles of "Upwards and Onwards" with great pleasure. Still, if I were to purchase all the Potatoes which he commends, I should have no room for Rosea.

I do not hold the doctrine of finality, or complete Potato perfection; still, as I am never without most excellent Potatoes "all the year round," I discard and introduce warily. I do not like turning off a servant whose faults I know for one whose faults I have yet to learn. I think we cry up and cry down commodities too hastily. Excellent Potatoes in certain years, and under certain circumstances, turn out occasionally bad. In the year 1865 nothing could be more close and ill-flavoured than the old Ashleaf; and in 1866 the excellent Royal Ashleaf sent out by Mr. Rivers, though good, was not equal to itself in the year 1865. For this reason it is well to grow more sorts than may be wanted.

As regards freedom from disease, it completely depends on circumstances. Some years ago the Rev. T. Case, the vicar of Horton, sent me the Red Ashleaf, warranted to defy disease. Alas! the tubers were complete pulp. The Grammars (a rough deep-eyed Fortyfold), very good this year, were given me by a blind parishioner under the name of "Rough Reds." Being a late variety I planted them very late, and they escaped the disease from which other Potatoes suffered much. The next year I planted them in a clover ley, on high, chalky ground, where no Potato had been planted for eleven years, and they were pulp. I must here ask "Upwards and Onwards" to tell me whether the blotches in the leaf are cause or effect. I fancy they are the effect of disease. Except electricity (not an idea of my own; I detest plagiarism unowned), I do not know what could in the year 1846 have affected the Potatoes over the whole world so instantaneously and synchronously. I have never yet been able to discover whether the attack in the first place was in the haulm, or roots and tubers. My present theory is (and I must admit that my theories hitherto have been fallacious), is that the visitation of 1846 weakened the cellular tissue, and that Potatoes have not yet recovered from it. Hence seedlings newly raised are frequently advertised as exempt from disease. When the disease broke out I was living at Critchill, and had an acre and half of Early Dugdale in a field which I rented of my late much-esteemed friend, Mr. Sturt, and I sold the crop, about half a crop—*i.e.*, a quarter of a sack a-perch, to him. They were supposed to have been one of the best crops in the neighbourhood—a good poor man's Potato. From that time to this I have been as much perplexed with the Potato disease as about fate. My "rule absolute" about the Potato disease has long been disowned by the chancery of facts, or the fortuitous concurrence of atoms. This being so, as I am but a "grasshopper" in the presence of "Upwards and Onwards," I wish he would tell me whether the ulcer on the leaf, the visible precursor of misery (for the cause may be beneath), is cause or effect. As soon as a medical man knows the disease and its seat, he may apply a proper remedy. Napoleon, at St. Helena, encouraged his doctor thus —"We are a machine made to live for a given time. You work in the dark, and thrust your crooked instruments into us, and for once that you relieve us you kill us a hundred times."

Now, I confess that I have been working in the dark, and I have this year thrust in a crooked instrument. I have planted, beginning February 12th, under grass, in stony land, 5 inches deep, dressed with dissolved vitriol, Grammars, Red Robins, Scotch Downs, or Rocks, and Salmon Kidneys, the best of all Potatoes. The vitriol may be useful if the disease is fungoid, for there is no better match for fungi of all kinds; or it may fail, the disease being of another nature, such as imperfect cellular tissue, or loss of starch, the grand component of a Potato. Still it is good as a revealer of bad Potatoes. My servant's testimony is, "You can tell the diseased tubers even where you can see no disease: they turn blackish within half an hour after application." He showed me one. I could see no disease; I cut the Potato open, and in the heart of the Potato there was the disease. It is also good to keep off centipedes, and other insects that live on and exhaust the tubers. I mean to keep this lot on the flat. I remember forty-five years ago my father had a grassed orchard dug up and planted with Potatoes. They were flat-hoed, but not earthed-up. The crop was larger than I have ever seen since.

I will now end with Stephen's testimony. "Steeve" is my servant, good and trusty, and this is his testimony — that round white Potatoes produce more than kidneys of any colour, that skulkers left in the ground all winter produce healthy Potatoes free from disease, that large tubers produce more than small Potatoes, that Potatoes about the size of a hen's egg will weigh 20 lbs. heavier per sack than large Potatoes, that early planting is best, that kidney Potatoes should not be cut or planted till the eye starts; that digging Potatoes before ripe is a double folly, it does not stop disease, and spoils what would, if ripened, be good; that Grammars will give a heavier crop with little or no manure than any other sort; and that though for years his Grammars were far sounder than any other, yet this year, out of three sacks stored away, he has not more than one bushel of good ones. The mystery of the Potato disease is, as yet, the great mystery of the natural world.

The kidney Potatoes, of the Ashleaf race, I shall plant in broken ground, and shall water them early in June.—W. F. Radclyffe, *Okeford Fitzpaine*.

HAS A FOREMAN ANY VOICE IN THE MANAGEMENT OF HIS FIRES?

I am living in a nobleman's large garden establishment as foreman. The 4th of February was a very wet day, but cleared off towards evening, and, the wind shifting, the stars gave a very bright appearance. Thinking it likely that a frost would occur, I had the fires in the greenhouses lighted.

I went to the glass houses about half an hour afterwards, found the thermometer standing at 39°, and I ordered the fire to be slackened. At the same time I had a vinery that had been started about three weeks, and in which the Vines had shoots about an inch long. This house was shut up in the afternoon at a temperature of 65°; on entering it at 8 P.M., I found the thermometer standing at 62°, with a little heat in the pipes. I banked my fire for the temperature to fall to about 55° by morning. My master coming out at the time altered all my doings for the night, and by his orders the stove fire was again set burning. The consequence was, on entering the vinery in the morning, a strong fiery heat was felt, and instead of finding the thermometer at 55°, it was then standing at 72°. The gardener coming in and finding the temperature so high, ordered air to be given very freely, and in an hour the house was standing at 62°. Do any of your readers think this was correctly treating an early vinery? I have lived in three other establishments as foreman, and never have seen a vinery treated in this manner before. From a garden boy I was always taught never to put air on for lowering the temperature, but to give it slowly as it was required, and to let the warmest time be in the middle of the day.—A Subscriber, H. M.

[The subject is not devoid of importance, but it is one always unpleasant to meddle with, as no general rule can be advanced as to the relative positions to be occupied by a gardener and his foreman and assistants, but each establishment must be left to form rules and regulations for itself. I have no hesitation, however, in submitting the following observations suggested by your case, looking upon it, however, as a one-sided statement:—

1. Whatever the abilities, the intelligence, and the attention of a foreman or an under gardener, so long as he remains in these positions it is his duty to carry out the wishes and commands of the head gardener, as he is the chief responsible party; just as it is the duty of the head gardener to serve his employer in the way he peculiarly wishes to be served, giving up so far any partialities of his own, to attend chiefly to that which an employer mostly values.

2. In large places matters will not go on well unless there is a reciprocal feeling between the head gardener and his assistants, and a general wish to make the most of the circumstances. I have no faith in the old dictum, addressed by a master to a man, "What business have you to think?" On the other hand, an assistant is valuable just in proportion as it is perceptible that he does think—that he acts from thought, and not from mere routine. I have faith also in the old statement that two or more are better than one, and in setting about a job the workman may propose a better mode than that at first pointed out by the master; and in such a case, if wise, the master will adopt the plan of the workman, because thus he will secure a thorough coadjutor, instead of a mere working, looking-to-the-clock man, and because, again, a man feels an interest in making his own plan appear the best by the less

time that it takes to carry it out. In all such cases, however, it should never be forgotten that the decision at last rests with the master, and when that decision is given an honest assistant will carefully carry it out, though it be not what he thinks the best under the circumstances.

3. The whole account of the management of the furnaces does you credit. Your examining the appearances of the sky, your noticing the outside thermometer and the changes since the last visit, your reading the thermometer inside the forcing-houses, and satisfying yourself as to the heat in the pipes or heating medium, are all very simple matters; but such it is very difficult to get young men to look upon as of much importance, and without attending to them the management of fires is a mere matter of chance. You showed also the necessary attention in lighting the greenhouse fires, and in such a case of overheating as that to which you refer, I would have preferred giving a very little air, damping the path and floor, and allowing the house to cool gradually.

4. While approving of your attention and consideration, I cannot for a moment give up the right and duty of the master to come to a different conclusion, and to express his wishes accordingly, so as to have some more heat in the pipes before banking the fires up; and I fear it must be added that he would have too much right to feel dissatisfied and annoyed, when, instead of the little more heat in such a changeable night as the 4th of February, there should be such a fiery heat in the house in the morning, and the thermometer about 17° higher than was deemed necessary. Such a result gives too much reason for the suspicion that, not thoroughly knowing your place as a servant, you were annoyed that your arrangements were in the least interfered with, and since heat was wanted, heat should be given, and in a pet you piled on the fuel careless of consequences. If I am right in this conclusion, then I would impress on you in all kindliness, that such outbursts of spleen and impatience of control will more than counterbalance your other good qualities—intelligence, diligence, and attention.—R. F.]

THE ROYAL HORTICULTURAL SOCIETY,

AND THE EXECUTIVE COMMITTEE OF THE INTERNATIONAL HORTICULTURAL EXHIBITION.

We are informed that at a meeting of the Executive Committee of the International Horticultural Exhibition, held on Thursday the 14th inst., the motion which was placed on the minutes at the meeting of the 20th of November last, was carried unanimously. Resolved—

"That a communication be made to the Commissioners of the Exhibition of 1851, informing them that the Committee of the International Horticultural Exhibition have now remaining a balance of eighteen hundred pounds (£1800), which sum they are willing to invest in the purchase of the Lindley library and other books, to form the foundation of a Botanical and Horticultural Library, to be attached to the Royal Horticultural Society, provided Her Majesty's Commissioners, who are interested in the advancement of the South Kensington estate, are willing to provide a suitable reading-room, with glass cases, for the reception of such library. The room and books to be for the use of Fellows of the Royal Horticultural Society, members of other societies, and gardeners generally, under such rules as may be agreed on. The Horticultural Society to nominate one of its officers or a clerk to look after the same. The room and library to be invested in the names of seven Trustees—two appointed by the Commissioners, two by the Royal Horticultural Society, two by the International Committee, and one by the six above named."

The above is the best reply that could be given to the conversation that took place at the annual meeting of the Royal Horticultural Society, a report of which appeared in our last number. It is now apparent that the proposal for the munificent donation which the International Committee have placed at the service of the Royal Horticultural Society has been on the minutes ever since the 20th of November last; and we were not wrong when we stated in our last that some misunderstanding must have existed on the subject, for we believe that on an interview having taken place between Sir Wentworth Dilke and Mr. Wilson Saunders, a perfect understanding was at once come to. It is much to be regretted that Mr. Edgar Bowring, who, as a member of the Expenses Committee, evidently came prepared to raise the question at the meeting, did not signify his intention to Sir Wentworth Dilke, who would no doubt have been in his place to make a full explanation, both on behalf of himself and of the Executive Committee, and thereby have prevented an impression going abroad that the International Committee did not intend doing anything for the Society with the surplus fund derived from the Exhibition.

It was perfectly natural that on such a subject the Fellows of the Society should desire to have some information, and we are not surprised that the question should have been raised, so that they might know the relation in which the Society stood to the International Committee.

And what was that relation? Looking at the correspondence and the documents that were published in our last, we gather that there was an understanding of a vague and indefinite character that the Committee were to do "something." To this both parties seem to assent, and in the correspondence both admit the principle. The minute of the Council says, "Should there be any surplus in the takings of the Committee, the liberality of the Royal Horticultural Society will be duly acknowledged." Sir Wentworth Dilke says, "In conversation something was said about doing something." Mr. Wilson Saunders says, "That Sir Wentworth Dilke, on the part of the Committee, acknowledged the principle, that in case of any surplus accruing to the International Horticultural Exhibition the Royal Horticultural Society should have a claim therein." Now, on the part of the International Committee the principle was accepted and acted upon so long ago as the 20th of November last, when the motion which was carried at the meeting on the 14th inst. was placed on the minutes. We cannot, therefore, but regard the action taken by Mr. Bowring as precipitate, particularly as allusion was made to the purchase of the Lindley library in the report of the Council, thereby indicating that the International Committee did intend to do "something."

ROYAL HORTICULTURAL SOCIETY.

February 19th.

Floral Committee.—This was a deeply interesting meeting from the number of the Orchids exhibited, among which were several of great beauty and rarity. A group of cut Orchids, from Mr. Anderson, of Meadow Bank, contained some species that are exceedingly rare, such as Batemannia Beaumontii, Epidendrum Cooperianum, Vanda gigantea, a beautiful Oncidium of great value, and Lælia superbiens; the latter having a magnificent bunch of flowers was awarded a special certificate. Mr. Rucker also exhibited a cut specimen of the last species, but in size and depth of colour it was far exceeded by Mr. Anderson's flower. Cut blooms of some Lycaste Skinneri were shown by Mr. C. Penny, gardener to H. H. Gibbs, Esq., of St. Dunstan's, Regent's Park, and were described by Mr. Bateman, as "the finest ever seen." They were of unusual size and beautifully marked, and were awarded a special certificate. Messrs. Veitch & Sons received a special certificate for a large and beautiful collection of Lycaste Skinneri, shown in honour of the memory of the late Mr. G. U. Skinner. It was remarkable how freely many of these had bloomed. Mr. Wilson, gardener to W. Marshall, Esq., of Clay Hill, Enfield, had a large group of Cattleya Warscewiczii, in varieties, some of them of great beauty, to which a special certificate was also awarded. The same award was made to Messrs. Low & Co., for collections of Lycaste Skinneri and Oncidiums, the latter containing some varieties of great interest. Dr. Pattison, of St. John's Wood, also received a special certificate for a collection of Orchids, among which was Odontoglossum species, a supposed variety of O. Warnerianum, and resembling O. Cervantesii. The same award was made to Messrs. E. G. Henderson & Son, for a group of Cyclamens, comprising varieties of C. persicum, coum, and Atkinsii. The former contained some marvellous flowers, of great depth of colour and large size. They were one-year-old seedling plants, and literally masses of bloom.

First-class certificates were awarded to Oncidium species, from Mexico, shown by Messrs. Low & Co., a new variety, having a great resemblance to O. pelicanum, without the brownish lines. The habit was very close and compact; to the same for Odontoglossum maculatum superbum, considered to be a very distinct variety, the dark colour being much deeper in this than in any other, the petals also being thick and broad, and to Messrs. James Garaway & Co., Durdham Down, Bristol, for the following varieties of seedling Amaryllis, a magnificent lot of which were produced by them, apparently seedlings from A. aulica and vittata—viz., Olivia, rich scarlet and crimson shaded, pure light throat; Cleopatra, bright orange scarlet, shaded and veined with glossy crimson, the colour reaching to the base of the segments; H. Gibbs, carmine crimson, the spine of the segments pure white and feathered with the same; and Helena, orange scarlet, with slight shading of crimson, dwarf habit, and of fine form. A second-class certificate was awarded for Juliet, bright orange scarlet, shaded with purplish crimson, and clear throat; and a special certificate to six plants of A. Ackermanni pulcherrima, also very rich.

Second-class certificates were awarded to a variety of Asplenium differme, from New Holland, shown by Messrs. Veitch—it was considered by the Committee to be a good basket Fern for a hardy greenhouse—and to Griffinia Blumaria, from Messrs. E. G. Henderson and Son. The small lanceolate foliage resembles that of Eucharis ama-

zonica. It is a shy bloomer, flowering only once in three or four years. A like award was made to Bryonopsis laciniosa, from Mr. W. Earley, of Digswell, having fragrant white blossoms with a curious thready fringe, resembling somewhat the flowers of the Snake Cucumber. It is said to produce berries, but will require crossing, as there did not appear to be any female flowers on the plant. It is an evergreen hothouse climber, and will be valuable for bouquets. Also to Oncidium species, from New Granada, in the way of O. sphacelatum, from Messrs. Low and Co. It has a good habit, and the flowers are very showy.

Special certificates were awarded the following:—To Mr. Sherratt, gardener to James Bateman, Esq., of Knypersley, for cut specimens, with fruit, of Citrus japonica, or Japanese Citron, from a warm greenhouse. The fruit is highly ornamental, and was said by Mr. Fortune to succeed better in the northern districts of China than in the southern. It was also thought that it might be cultivated out of doors in the warmer portions of the south and west of England. This Citron was originally sent to the Royal Horticultural Society in 1854. To a magnificent truss of Rhododendron argentea, from Mr. Squibbs, gardener to Mrs. Turner, Rook's Nest, Godstone, said to be of a purer colour than R. Falconeri, and to be the same as R. macrantha, from Bhotan, sent out by M. Van Houtte, of Ghent, a few years ago. To a splendid and well-grown specimen of Dendrobium speciosum, from Mr. Wilson, gardener to W. Marshall, Esq., Enfield, with four immense spikes of bloom. To Messrs. Veitch & Sons for a half-standard Aucuba japonica vera, in a tub, the plant being very symmetrical, and well covered with berries. The diameter of the specimen was about 2½ feet.

Other subjects of interest but which did not receive awards, were a species of Dendrobium, named by Mr. Bateman D. Bullerianum, resembling D. Devonianum without the fringe; it was considered doubtful whether it was a cross or a species; it came from W. W. Buller, Esq., of Strete Raleigh, Exeter, and was not in good condition: Odontoglosssum nebulosum var., from J. Day, Esq., of Edmonton, considered a good variety, but too far advanced to judge accurately of its merits; Begonia Earleysii, a supposed seedling from B. phyllomaniaca, larger than B. digswelliensis, but showing too much of the large green seed-pods, which detract from the attractiveness of the flowers; a large plant of Camellia Mathotinna, from Messrs. Veitch & Sons, the flowers of which were paler in colour than is usually seen; cut flowers of the old Canarina campanula, from Mr. Davis, gardener to W. Stride, Esq., Redbridge, Southampton; some plants of Fuchsia Cloth of Silver, a sport of a creamy-green colour, but too young to judge of its merits; Iresine Herbstii splendida, a well-coloured specimen of I. Herbstii, not distinct enough to be classed as a variety; and I. Herbstii aureo-reticulata, pale-green leaves veined with creamy yellow.

Fruit Committee.—Several collections of Apples were exhibited, among which one from Mr. Whiting, of the Deepdene, Dorking, obtained a special certificate; it comprised fine examples of Adams' Pearmain, Blenheim Pippin, and Alfriston. Mr. Parsons, gardener to W. J. Blake, Esq., Danesbury, had a similar award for numerous dishes in excellent condition, and among them Blenheim Pippin was especially fine, both in size and colour. Mr. Earley, Digswell contributed Sam Young, Cockle Pippin, Fearn's Pippin, and Dredge's Fame, as well as a very good dish of Ashmead's Kernel from Gloucestershire. T. Laxton, Esq., of Stamford, sent two seedling Apples, named respectively Stamford Pippin and Welland Pippin, neither of which, however, was considered of such merit as to deserve a certificate; and from Mr. T. Short, gardener to Viscount Eversley, Heckfield, Hants, came Melon Apple, a showy American variety of excellent quality, ripened on a half standard in an orchard. Mr. Sherratt, gardener to J. Bateman, Esq., Knypersley, exhibited the Kumquat (Citrus japonica), as produced on the plant, and received a special certificate; accompanying it were some of the preserved fruits as sold in the shops. Further reference to this small-fruited member of the Orange family will be made in the proceedings of the fortnightly meeting.

In the Vegetable department Mr. Earley exhibited excellent Shallots, and a good and rather numerous collection of Potatoes, the best of which appeared to be Hardcash, Queen's Own, Mona's Pride, Royal Ashleaf, and Myatt's Ashleaf Kidneys, and of Round varieties Giant King, Soden's Early Oxford, and Victoria. From Mr. Dean, seedsman, Ealing, came Fearnought Cabbage, from a garden in the south of Hampshire, where Broccoli and Kales were much injured by the severity of the late frost, whilst the Fearnought was scarcely touched. It is described as being the result of a cross between the Dwarf and the Hearting Kale. It is also stated to be a delicious table vegetable. M. Ernst Benary, of Erfurt, contributed large examples of Celeriac, which is much used in Germany; but they were pithy, and not good either raw, in salads, or boiled.

Fortnightly Meeting.—Mr. Bateman, in proposing that Mr. Wilson Saunders should take the chair, said that whilst all must regret the resignation of Earl Grosvenor as a member of Council, they could not but rejoice to learn that in accordance with the rules of the Society the Council had that day unanimously elected Mr. Wilson Saunders to fill the vacancy. Mr. Wilson Saunders having returned thanks the proceedings commenced with the election of twenty-four new members and the admission into union of six Societies—namely, the Chertsey and District Floral and Horticultural Society, East Neuk of Fife Horticultural Society, Elvetham, Eversley, Bramshill, Yateley, and Minley Horticultural Society; Largo Field Naturalists' Society; Neston, Burton, and Heswall Floral and Horticultural Society; and the Royal Jersey Agricultural and Horticultural Society.

The awards of the Floral and Fruit Committees having been reported, the Rev. M. J. Berkeley offered remarks on some of the plants exhibited and other subjects. Allusion was first made to a variety of Weeping Ash, which had the peculiarity of not producing seeds, but only polleniferous flowers, and then to the magnificent Saccolabium shown by Messrs. Veitch at the December meeting, and which was imported under the name of S. giganteum, but which had been considered almost identical with S. violaceum. This, however, was not the case, for in S. violaceum the lip is strap-shaped, whilst in S. giganteum it is orbicular, besides which several other structural differences were pointed out. The identity of Thuja gigantea with T. Lobbiana, and of the Thuja gigantea of gardens with Libocedrus decurrens, both of which facts are referred to in another page, was then stated, as well as Mr. Bause's success in propagating Chimonanthus grandiflorus. Messrs. Garaway's fine Amaryllises, and some plants from Mr. Wilson Saunders were then specially noticed; of some species of Sonchus from the latter gentleman, it was remarked that nothing could be more ornamental for table decoration. Of the Bryonopsis, shown by Mr. Earley, it was stated that the plant would afford a dozen fresh flowers every day, and was therefore valuable for bouquets, besides which, it was said to have showy crimson fruit, and was probably allied to the Bryonopsis erythrocarpa, which was so beautiful in the conservatory last year. The charming varieties of Cyclamens from Messrs. Henderson next occupied attention, and it was stated that raising such was a mere matter of chance, for out of a thousand seedlings not one, perhaps, would prove good; Mr. Berkeley also added that many of those exhibited had been raised from seed not two years ago. In connection with some Mushrooms which had been brought before the Fruit Committee, it was mentioned that they were not all Agaricus campestris, some appearing to belong to A. arvensis, and the importance of growers collecting spawn from places where Mushrooms are naturally finest, was urged, and in this way, too, there was every probability of an improvement being effected in the strain. The sad effects of the late frost were next touched upon, and no part of the country, Mr. Berkeley said, appeared to have suffered so much as the valley of the Thames, where extremely low temperatures were recorded. At Chiswick, for instance, the thermometer indicated — 11, at Slough — 8, and at Kew — 4; but there might be some doubt as to the perfect correctness of some of these indications. The damage done to vegetation had been very great. At Kew a large tree of Cupressus macrocarpa had become a wreck, Araucarias had suffered, and at Chiswick the largest Deodar had suffered severely, whilst the variety robusta was scarcely injured. It was noticed both at Kew and Chiswick, that where plants were covered with snow they were safe, and that the tips of branches bent down under the snow were unhurt, whilst the exposed parts were browned. Mr. Berkeley also stated that in some parts of the country trees were still suffering from the effects of the frost in the winter of 1860-61, having been injured in the stem. It would be interesting to obtain particulars as to what forest trees had been severely injured during the past frost.

Mr. Wilson Saunders considered that a great lesson was to be gained from the effects of the late frost, and particularly in respect to the great preservative action of snow. He then exhibited to the Meeting specimens of Deodars, Garrya elliptica, and other shrubs, showing how they had been affected where exposed, and that they were little, if at all, injured where covered with snow; and he remarked that many plants which will live in a very cold climate will be killed in this country because they have not the same snow covering. Variegated plants, too, will not stand cold so well as the original species; thus, he had specimens of the Irish Ivy, showing that to be uninjured, whilst the variegated Common Ivy was killed; the Common Periwinkle was hardy, but its variegated form would not stand cold, and the same with many other plants. It was also worthy of remark that plants of the same kind are not equally hardy in the same situation: hence in selecting plants it is very necessary to choose those having a good constitution.

Mr. Berkeley, in answer to a question put by Mr. Wilson Saunders, as to why the Deodar should suffer here, said that though the tree was subjected to an extreme degree of cold in its native country, yet before the frost set in there were cold rains, and growth was brought to a standstill; but in the valley of the Thames the trees before the last frost were full of sap.

Major Trevor Clarke desired to state that the late severe frost had enabled him to prove the entire hardiness of Disa grandiflora, a most interesting and beautiful African plant. He had had it out of doors for three winters on trial, and only needed such a test as the present year afforded. It would now become a most useful addition to our hardy plants.

Mr. Bateman said his duties with respect to the Orchids would be onerous, for there was quite an inundation of beautiful specimens of that order. Among Cattleyas the palm must be awarded to the variety from Mr. Barnett, of Blackheath. Mr. Anderson, gardener to T. Dawson, Esq., of Meadow Bank, near Glasgow, came next with a large number of rare and interesting kinds, many of them exhibited for the first time. Among them was Oncidium nubigenum, which, though it might appear insignificant, was not the less remarkable, for it had been found at an elevation greater than any other—namely, 14,000 feet

above the level of the sea. Then there was Batemannia Beaumontii, one of a genus named after him by Dr. Lindley; and he (Mr. Bateman), felt much gratified at the honour when the first species, B. Colleyi, was named; but unfortunately it had an unsavoury odour, and B. Beaumontii was worse still. Mr. Anderson also sent a splendid spike of Lælia superbiens, one of the grandest discoveries of his (Mr. Bateman's), lamented friend Mr. Skinner, who, when he found it, said it could be seen nearly a mile off in the clear atmosphere of its native country. The spike shown, he was happy to say, would be presented to Her Royal Highness the Duchess of Cambridge. Another specimen of the same Lælia, though not so fine, came from Mr. Rucker. A very fine specimen of Dendrobium speciosum, a plant which any one might grow, was sent by Mr. Wentworth Buller; also an interesting new Dendrobium, which he (Mr. Bateman), had ventured to call Dendrobium Bullerianum. There was also a new Odontoglossum from Messrs. Low, which would be figured in the "Botanical Magazine;" and from Mr. Wilson, gardener to W. Marshall, Esq., came some of the finest Cattleyas he had ever seen. He wished, however, to impress on those present that Cattleya pallida, Trianæi, quadricolor, Warscewiczii, and Wagneri were all varieties of one and the same species.

With regard to the Kumquat, Mr. Bateman said it had a peculiarly ornamental appearance where growing on the back of one of his stoves, or rather a warm greenhouse. On referring to an old number of THE COTTAGE GARDENER, he found that Mr. Beaton spoke of it thus:—"From the Garden of the Society came fruit of the Japan Citron (Citrus japonica); this is not the Mandarine Orange, or the Otaheite Orange, of which they make such pretty little standards, but the fruit is as small as that of any in the tribe, and of the shape of a small Ashleaf Kidney Potato; the rind is most fragrant, and the whole fruit is highly prized by the Chinese; when preserved in sugar they call it the Cum Quat." Mr. Fortune had sent him the following information:—

"I am well acquainted with the Kumquat, and have little doubt your plant was one of those, sent home by me to the Horticultural Society during my first visit to China (1843 to 1846). It is, I believe, the Citrus japonica, and is largely cultivated both in China and Japan. In China it attains a greater degree of perfection in the central provinces than it does in the more southern, and ought to be hardy, or nearly hardy in the south of England. Perhaps, however, a higher degree of summer heat may be necessary in order to have it in perfection with us. Of one thing you may be quite certain, it is much hardier than the Common Orange. The common China Orange is to be had in perfection in the south of China only, and is not cultivated in the district farther north, where the Kumquat grows so well. The bushes, 3 or 4 feet in height, are very beautiful in November and December when loaded with fruit, which ripens at this season of the year. All winter long the fruit is very plentiful in the markets. If you have tasted the fruit you will remark that the rind is sweet and of an aromatic flavour, while the pulp is very acrid. As a preserve it is much esteemed and largely used. It is exported in considerable quantity to Europe and America. I daresay you have frequently eaten it amongst those Chinese preserves sold by Fortnum, Mason & Co., and others."

The plant has this peculiarity—it cannot be propagated by cuttings, but must be grafted on another tree of the same kind—Limonia trifoliata; and, Mr. Bateman added, cuttings would be distributed.

This offer of cuttings called to his mind one made on a much more extended scale by a Mr. Hullett, who, in a paragraph in the *Times* headed "New Food," directed attention to the Chinese Sugar Grass, stated that it would produce five times as much as Wheat, that the stems could be used as cattle food, &c., and with unprecedented liberality offered a few grains to those who would send a stamped and directed envelope. Mr. Bateman had sent for some, but not in his own name, and received seeds along with a printed memorandum, one paragraph of which explains the whole of his object, and which is as follows:—"Seeds can be supplied in packets at 1*s.* or 5*s.* each." Now it was stated in the *Times* by Mr. Hullett that he had 9,000 applications, and in *Bell's Weekly Messenger* the number was given at 20,000; but as the seeds were nothing more than those of Sorghum saccharatum, or Holcus saccharatus, the whole quantity required to supply all the applicants could be had for about a shilling. One seedsman offered him (Mr. Bateman) 10,000 seeds wholesale for 4*d.* As to the Sorghum it had been tried in this country, and it was found that the summers are not warm enough to ripen its seed, and even Messrs. Sutton in the fine climate of Reading could not get it to succeed. For agricultural purposes it was found nearly valueless.

Mr. Bateman said that he now came to what to him was an exceedingly painful subject, the death of his friend Mr. Skinner, whose bright genial countenance was seldom absent from the Tuesday meetings. Mr. Bateman then gave a sketch of Mr. Skinner's life, the leading particulars of which have already appeared in these columns. It seems that Mr. Skinner in early life was desirous of entering the navy, but in deference to the wishes of his friends he took a situation in Messrs. Barclay's Bank. He afterwards was in business at Leeds, but finding an opening in the then little known republic of Guatemala, he went there, and soon entered into partnership with Mr. Klee, the Prussian Chargé d'Affaires. There he directed his attention chiefly to birds and insects before he took to gathering plants; but in consequence of some birds which he sent to the Museum at Manchester, Mr. Bateman ventured to send him some sketches of plants, and directions as to the mode of packing such for transmission to this country. Soon a box came, and along with many other new plants was Barkeria Skinneri. Other plants sent home by Mr Skinner were Lælia superbiens before alluded to, Odontoglossum pulchellum; but his crowning work was Lycaste Skinneri. "Happy, indeed, am I, far more happy than he would be," said Mr. Bateman, "that his name will live in it." It flowers in the coldest months of the year, and no plant is more useful or lasts better. Mr. Bateman next referred to the many specimens of birds which Mr. Skinner had sent home, and of which there were numerous examples with gorgeous plumage on the table. Mr. Bateman then gave an account of Mr. Skinner's death on the Isthmus of Panama from yellow fever, caught, it is believed in a fever-tainted ship, and said that Mr. Skinner had long been a widower, but had left two daughters and an aged mother to bewail his loss, and with whom he intended to have passed the evening of his days under the roof of his brother, the Rev. J. Skinner. His last letter was to Mr. Veitch, who had set aside a room, and was putting up a house for Mr. Skinner's collections.

Mr. Wilson Saunders proposed a vote of thanks to Mr. Bateman, which was unanimously accorded by one of the most crowded Tuesday meetings which have ever been held.

Among the visitors in the early part of the afternoon were their Royal Highnesses the Duchess of Cambridge and the Princess Mary.

A DEVOURER OF THE RED SPIDER.

HAVING frequently seen in THE JOURNAL OF HORTICULTURE inquiries as to the means of destroying the red spider and other insects, I beg to offer one which I discovered last summer. I had a favourite bird called the "Indigo Bird." My astonishment was great when I let him out of the cage, having for two years fed him on canary seed, to see him devouring insects of every description. The consequence was, I had no red spider, &c., on my Vines or in my greenhouse afterwards, for I frequently let the bird out of his cage to do his gardening work.

The bird is a beautiful blue in summer, but in the winter brown like a sparrow. The outside of my windows has wires, so that no bird can escape.—ST. LEONARDS.

BIRMINGHAM PRIZE POTATO.

ALL who know this excellent Potato are aware that it produces both round and kidney-shaped tubers, and my object in writing is to ask whether it cannot be shown at our exhibition of fruits, flowers, &c., in both classes of round and kidney-shaped?

It was so exhibited at our autumn show of last year, and carried off the prize in both classes. This gave rise to a paper war between two clever gardeners in the district, Mr. Simpson, of Stutton Rectory, and Mr. Sheppard, of Woolverstone. Mr. Simpson declared the Potato in question could not be shown, and carry off the prize in both classes, while Mr. Sheppard affirmed it could. Which of the two was right in the matter?—W. C., *Ipswich*.

[We think it could be shown in both classes. We cannot see any justice in excluding first-rate round Potatoes because the plant which produced them also produced first-rate kidney-shaped Potatoes, and *vice versâ*. The prizes are offered for round and kidney-shaped Potatoes respectively, without any such restriction as that they should not be grown on the same plants; nor is there any just reason why there should be such a restriction. It is desirable rather than otherwise, that a plant should produce tubers of various shapes, and if it produced the best round, kidney, and Lapstone-shaped tubers, we see no reason why its produce should not take a prize in each of the three classes.—EDS.]

THE INTENSE COLD AND ITS CONSEQUENCES.

HADDINGTON.—The snow having for some time disappeared and mild weather having intervened, I have been enabled to inspect my garden more minutely than when I last wrote to you. As I said before, we have not had such severe frost since the winter of 1860-61, and the damage to gardens has consequently been great. Much difference in the effects of the frost is apparent in localities at very short distances from each other, plants on elevated ground escaping with less injury, while those in low-lying places in the neighbourhood of a river or stream have suffered most severely. My garden is under the latter influence, and it is injured accordingly. Except where the spurs are in direct contact with the wall, all the flower-buds of Apricots are destroyed. Some Pear trees appear to have suffered in a similar manner, a good many of the buds being deprived of all vitality. A large proportion seem sound and well expanded, but whether the embryo fruit is destroyed re-

mains yet to be seen. Roses are severely cut down, Noisettes and Tea-scented in general to the snow-line. The universal favourite, Gloire de Dijon, looks as if it had more life in it than others, but appearances so early are often deceptive. Laurustinus and Bays above the snow, are, in general, altogether, and Berberis aquifolium partially browned; tree Pæonies are killed to the roots; and even the tops of Leeks, not covered with snow, are whiteued.—John Ferme.

Gillingham, Norfolk.—The thermometer used here is one of Messrs. Negretti & Zambra's, placed 4 feet from the ground, and facing the north. We are situated about fourteen miles from Great Yarmouth, and twelve from Lowestoft. The greatest cold was during the night of the 4th of January, it then fell to 2°, or 30° below freezing. I may mention a few things which have suffered from the effects—viz., a large quarter of Cabbages is entirely killed, also about two hundred of Backhouse's Winter Broccoli standing on a south border; other kinds of Broccoli have not suffered much. Monthly Roses are killed to the snow-mark. Sweet Bay, Laurustinus, common Laurels, Rhododendron Smithii, Garrya elliptica, Elæagnus argentea, and Ilex maderensis have all been much scorched. Of Roses, Lord Raglan, Celine Forestier, General Washington, and a few others are much blackened. — John Batters, *Gardener to Admiral Henry Eden.*

Stakehill, near Manchester.—From a thermometer carefully tested for correctness and hung with the bulb 2 feet from the ground, the lowest reading was 5°, 27° below freezing. From 10° to 12° was the reading on most eveninga. Except in the case of slight drifts, the snow was from 2 to 3 inches deep. The situation is bleak and much exposed on all sides, especially on the W. and S.W. The following plants have suffered:—Common Laurels, Portugal Laurels, Sweet Bays, Aucuba japonica, Cotoneaster, Cedrus deodara, and Picea lasiocarpa, leaves mostly brown and scorched in appearance; Japanese Privet, lost all its leaves; Golden Hollies, Berberis Darwinii, Berberis aquifolium, Wellingtonias, and Pinus excelsa, much injured in the foliage, but not so much as those before named; Cedar of Lebanon, Thujopsis borealis, Red and White Cedars, Irish Yews, Garrya elliptica, Araucaria imbricata, Kalmia latifolia, Pernettyas, and some named Rhododendrons, injured more slightly. The following are perfectly hardy and uninjured:—Andromeda floribunda, Cupressus Lawsoniana, Skimmia japonica, Berberis Bealii, Retinospora obtusa, Cedrus atlantica, Picea Nordmanniana, P. pinsapo, P. nobilis; Thuja tatarica, T. Lobbi, T. gigantea; Abies Menziesii, A. Douglasii, A. canadensis; Pinus cembra, P. Bungeana, P. austriaca; Spruce, common and black, English Yew, Silver-leaved Holly, common Holly, Rhododendron ponticum, R. hybridum, and most named varieties; Juniper, Savin, Box, and Mistletoe.

I have had no time as yet to look over my deciduous shrubs. My Roses were protected by a mulching of stable-litter, not yet removed, and though many, I see, will require well cutting-in, yet they are not nearly so severely injured as they were in 1860, when all my Hybrid Perpetual Roses were killed to the ground. On standards, short and tall, every bud was then killed. Of those which I grew on their own roots, about three-fourths threw up shoots and in time became fine plants, the remainder were completely killed. I have for the last twelve years grown my Roses principally upon their own roots as soon as I could get them so. When I receive plants, principally new varieties worked upon short stocks, I plant them almost horizontally, not allowing the roots to be covered above 4 inches deep, and pegging down the plants at the junction of the stock and the head, this part is covered 2 or 3 inches deep with soil. In this manner I succeed in having them upon their own roots, mostly during the first season. Since 1860 I have invariably treated my new plants in this manner, and I have now a good collection of five or six hundred plants on their own roots.

These notes on evergreens are worthy of the attention of any one about to plant, especially in Lancashire. Had I three or four years since possessed the knowledge I now have, it would have saved me some money and much of the vexation which I now feel in looking upon so much withered, brown, and blackened foliage in the borders.—S. B. S.

WHAT SHRUBS AND TREES ARE NOT INJURED BY GAME?

Would any of your contributors be good enough to give a list of the shrubs and trees, decidnous and evergreen, which neither rabbits nor hares meddle with, for the information of those who, like myself, contemplate planting where these animals are extensively preserved? Perhaps some one whose grounds are much overrun with game would state what trees and shrubs have escaped injury from these depredators. In the little experience which I have had in such matters, I have generally found that newly-planted trees or shrubs, even when distasteful, are sure to attract either hares or rabbits, or both, and to suffer accordingly, unless planted on a large scale; and where a plantation consists of one species only, even if that is the reverse of a favourite with these animals, where they have a choice, it is, nevertheless, sure to suffer where there is nothing else.—E. F. G.

NOTES AND GLEANINGS.

It will be gratifying to our readers to know that at a meeting of Council of the Royal Horticultural Society, held on Tuesday, Mr. Wilson Saunders was re-elected to a seat on the Council on the resignation of Earl Grosvenor, and also to the office of Vice-President. This is not only a graceful compliment to one who has served the Society so well, but it is to the interest of the Society to secure the services of such as Mr. Saunders, who can render such signal benefit to its prosperity.

—— Mr. Bause, the clever propagator of the Royal Horticultural Society, has performed the great propagation feat of raising plants of Chimonanthus grandiflorus from cuttings. This, we believe, has hitherto baffled the skill of all cultivators, and the late Dr. Lindley offered a sovereign to the then propagator of the Society for every plant that was so raised. The method adopted by Mr. Bause was to put in the cuttings of the young wood of the current year, just after it was "set" in July last, and furnished with leaves. The pot was placed on the surface of the bed of the cooler end of the propagating-pit, and there allowed to remain till the end of November or beginning of December. On examination, Mr. Bause, finding they had calloused but not rooted, repotted them, somewhat disheartened, and with little expectation of success. They were placed in the same position; and on Tuesday last, when he turned them out with the intention of throwing them away, to his astonishment he found the pot filled with a mass of strong branching roots.

—— The Rev. M. J. Berkeley, who has been investigating the characters of the trees known in nursery collections as Thuja gigantea and Thuja Lobbiana, has discovered that what is known by the former name is not Thuja gigantea but Libocedrus decurrens, and that Thuja Lobbiana is the true Thuja gigantea. These facts Mr. Berkeley has ascertained by an examination of Lobb's specimens in the herbarium at Kew.

WORK FOR THE WEEK.

KITCHEN GARDEN.

As soon as the state of the ground will permit sow Walcheren *Broccoli* or Cauliflower; in hot summers it forms large heads when Cauliflowers only produce "buttons." *Cabbage*, sow Early York and a few of the fine Dark Red, also the Yellow Savoy and some of the Large Green Savoy, to precede the principal sowing of next month. *Celery*, sow a little White and Red. Sow the seeds either in a pan or box, and place it in a hotbed. About the middle of March prepare a slight hotbed, upon which a one, two, or three-light frame is placed, so as to be in readiness for pricking out the plants, which will require to be done during the last week in March; the surface of the bed is to be covered with slates or large pieces of turf, grassy side undermost, and upon the slates or turf place a layer 3 inches thick of well-rotted dung from an old hotbed, which requires a good beating with the back of a spade, after which add a layer of good soil 1 inch in thickness, and the bed is then ready for the reception of the plants. *Kidney Beans*, sow Early Dwarf Dutch where it can be sheltered, and in pans in very gentle heat. *Lettuce*, sow Paris Cos; and a portion of those Lettuce plants in frames may be planted out if frosty nights are not likely to occur. *Onions*, if the Portugal or White Spanish be sown on a good warm border, and afterwards transplanted, the size will be greatly increased. *Peas*, sow; Cormack's Prince Albert, which is somewhat earlier than the Early Charlton, Knight's Dwarf Marrow, and the Auvergne are varieties of Peas proper to be sown at this time. *Spinach*, sow the Round, also *Radishes*, between the rows of Peas and Beans. Prick out *Cauliflower* plants. Plant *Potatoes*, *Horseradish*, *Jerusalem*

Artichokes, *Garlic*, and *Shallots*; the Long-keeping Shallot is the best. Sow *Basil* and *Sweet Marjoram* in pots in gentle heat.

FRUIT GARDEN.

Preparations ought to be made for protecting the blossom of Apricots. Thin canvas screens are, of course, the preferable means, but where this material cannot be afforded Spruce branches or Fern may be employed. Under a broad coping the blossoms of Peaches, Nectarines, and Apricots, are rarely injured, unless on an east aspect, where they are apt to suffer from exposure to cold cutting winds so prevalent from that quarter. Bring up all arrears forthwith. Make sure of thorough draining. Plant high both at bottom and top. Finish nailing, and provide against insects.

FLOWER GARDEN.

Attend well to thorough cleanliness; hoe through or otherwise dress all margins or beds where Crocuses, Anemones, Snowdrops, Primroses, and other spring flowers are peeping up. Plant out Hollyhocks directly. This noble flower is well deserving of general cultivation. Its bold and pointed form stands out in fine relief in masses of flat-headed shrubs. Walks may be turned, raked, and rolled down in order to prepare them for receiving a thin coat of gravel. It occasionally happens from disease and other causes that a Tulip does not make its appearance above ground with the rest; a careful examination should take place, removing the soil till you come to the top of the bulb, when it may be found that the outer sheath or leaf is wholly decayed or rotten. In this case, after removing the diseased parts, do not return the soil, but allow the bulb to have free exposure to the air, covering from rain or frost with a hand-glass. The weather is now favourable for planting the Ranunculus, which should be proceeded with as speedily as possible. Auriculas, if not previously top-dressed, should be attended to immediately. As seedling Polyanthuses come into bloom, remove all that are inferior in shape, lacing, and colour. Should any fine-formed flower with other good properties come pin-eyed, it would be worth while to fertilise it, as all its progeny will not necessarily be pin-eyed, and occasionally some very promising flowers spring from one of this description.

GREENHOUSE AND CONSERVATORY.

Dispense with fires in the conservatory as much as possible, a temperature of 55° by day, and 44° by night will be sufficient for general purposes. Do not allow the heat to increase much by sunshine. There is as much skill displayed in retarding certain flowers as in hastening their flowering in the first instance, and to this end a canvas screen of a thin character should always be at hand to throw on the roof during the middny hours of very bright days. The seed of the Chinese Primrose may be sown in pans filled with light soil, and as soon as the plants are sufficiently large let them be potted off into three-inch pots, which should be well drained and filled with about equal parts of loam, sandy peat, and well-rotted manure or vegetable mould. The plants should never be watered overhead, and great care must be taken that they are not overwatered at the root, or they soon become sickly and die. Be sure to sow a little Cineraria seed as soon as you can. This, with another good sowing of Chinese Primroses and Cinerarias in April, will furnish a supply throughout the next autumn and winter, if high cultivation be carried out. As we are now upon the eve of a general shifting season, place some loam and peat soil in an open shed. Leaf mould should always be kept dry. Have all the pots clean, and, in fact, see that everything is ready for coming operations. This is a good time to sow all kinds of exotic seeds, either home-saved or imported. Place them in heat and they will soon germinate; prick off into other pots as soon as the cotyledons expand, and you will have plants established in a very short time. Attend to your ornamental trellis plants, they should always be in high order, and to accomplish this frequent attention is necessary. Forced bulbs, as Hyacinths, Narcissus, &c., should, after blooming, have the leaves tied up, and should be transferred to a cold frame, and when the most severe weather has passed away they should be turned out of their pots to feed in prepared beds.

STOVE.

Continue repotting such Orchids as need that operation. Stanhopeas, Acroperas, Dendrobiums, &c., suspended in baskets or on blocks, will now either require syringing occasionally or watering by some means. Many of these will have received little water since the end of October, and will have become excessively dry. Blocks may occasionally be soaked for a few minutes overhead in tepid water; also, baskets if very dry. If syringing is resorted to, choose a bright sunny day for the purpose, and syringe them well early in the morning. On such occasions keep up a brisk fire, and give air freely until the afternoon for fear of the moisture lodging on the expanding buds, which in some cases would prove fatal. Some of the winter-flowering stove plants, as Geissomerias, Eranthemums, Plumbagos, and Justicias, now exhausted, should be cut back a little and left to break, when they may be disrooted and placed in smaller pots. They will make large and early specimens for next autumn, whilst cuttings from them struck immediately they break, will furnish succession plants of a smaller size for dressing front shelves. The temperature should now be allowed to rise freely on bright days in the early part of the afternoon, remembering that a rise by means of solar heat alone can do no harm for a few hours even at this period, provided it do not exceed 80°.

FORCING-PIT.

Continue to increase atmospheric heat and moisture at fitting periods. Attend to subjects for succession. Watch the worm in the bud of Moss Roses, fumigate for thrips, &c., and see that the plants are duly watered with tepid liquid manure.

PITS AND FRAMES.

Prepare a gentle hotbed to receive fresh-potted plants, and to nurse such as are required to be excited for affording cuttings. Sow tender annuals for early blooming. Give air and water, and repot plants that require it. Pot off all rooted Calceolarias that were put in in the autumn, to make room for more tender plants. Continue to put in cuttings of all kinds of plants that are wanted to decorate the flower garden.—W. Keane.

DOINGS OF THE LAST WEEK.

KITCHEN GARDEN.

Cabbages.—Earthed up some Coleworts planted late in autumn, and which, contrary to general results, have stood the winter well as yet, thanks to the snow, which kept the most severe frost from touching them. These will come in useful as our earliest cutting or gathering in spring, for our spring Cabbages will be a little later than usual. We have previously stated that in our plantation, though surrounded by a common net, there was not a single plant left, the rabbits, &c., making holes in the netting, or finding their way under it. To make amends, we turned out some hundreds of nice stubby Cabbage plants from pots which had been placed in the orchard-house and under glass frames, where the plants could have a little heat at the roots, and the tops be kept stubby and cool. In such positions they grew rapidly; and as the pots became filled with roots we turned the plants out on the 15th on a bank sloping to the south, being in expectation of the rain that followed on that evening and the next day. Such plants will grow right on without any check, and where no four-footed devourers of consequence will be able to attack them. These will now be little later than those planted out in September, but then, of course, the labour has been considerably increased—a matter of much importance when the market value comes to be closely looked at. Such schemes must be resorted to at times when we would not have crops later than usual. Many will make allowance for failures, accidents, and depredations, when the causes are seen to be beyond the manager's control, but will forget all about these causes when there is the slightest stint in the supply. This shows the necessity of constant watchfulness; and when an accident happens now and then from forgetfulness or inattention, the fine weather that succeeds seems to upbraid us every hour. It is bad enough when sowings and plantings are rendered next to nugatory through no remissness of our own, but from depredators that nothing but destroying them or guarding by wire netting can protect us from; but there is at least the freedom from self-accusation, the worst of all to endure. Even in such cases much labour is often required to bring up our leeway. Last season our early Cauliflowers, independently of trapping and poisoning, were so injured by rats, that, not to be behind, we had to hurry on a score or two under some old sashes in a pit. Singularly enough, we have not seen a Cauliflower plant touched as yet this winter. Last season nothing seemed to come amiss to the rats, and though many were trapped the numbers of the depredators were but little diminished.

Peas.—Sowed more in semicircular drain-tiles, but chiefly in pieces of turf 9 inches long, 4 inches wide, and from 2 to 3 inches in thickness, the turf reversed, a groove scooped out

in the centre, the Peas sown, and then covered with leaf mould. These were placed under some old frames, with just a little heat below them. We like tiles better than turf if we have enough of them. In filling them with rich earth we place a lump of rotten dung or leaves in each end. The Peas seem to grow more freely when transferred from such tiles, or even from boxes, than from turf, as, if the turf is firm, it seems to bind the young stems of the Peas too firmly, and so prevent their free expansion. Our ground is yet too wet to do much in this way out of doors, even if we could do so with safety. Last year about this time we thought we might sow with comparative safety, as we had not seen a pheasant about the garden for weeks, but before they were sown three days our winged enemies knew all about it; repeated sowings were just repeated feedings to them, and even tarring the ground would not keep them away; wire netting, or even common netting, would have baffled them, if small enough in the mesh—from ¾ to 1 inch, for if the openings were from 1½ to 2 inches there was every chance of many birds hanging themselves in the netting. The pheasant will cunningly shove his head through netting barely large enough to admit it, but he has little idea of extricating it.

In the last page of advertisements but one in the number for the 14th of February is a representation of *wire guards* in yard lengths at 1s. per yard, which would make a secure protection for Peas and other crops sown in rows, and which, besides answering many purposes of protection, would last a long time when taken care of. If this meet the eye of the advertiser, it would be well if he would state the width and height of the guard, the size of the small openings, and whether the wire is plain, japanned, or galvanised. These matters would be of importance to many, especially amateurs, who have been making inquiries on this subject, and to some of these we had recommended mere makeshift and cheaper plans, such as strips of wood placed on each side of the row, and a piece of fine netting fastened on the top. Two boards three-quarters of an inch thick, or even half an inch thick, with cross pieces to keep them together, 5 inches apart at the bottom, and three-quarters of an inch apart at the top, would keep Peas from the larger birds, but we question if such modes would be so economical in the end as these neat wire guards, with their iron feet to go into the ground, and at any rate they would not be so useful for general purposes, or for giving protection to rather tender plants when first turned out. When the Peas are 2 or 3 inches above the ground pheasants and other birds will trouble them but little. They are most ravenous at them just when the radicle is extended and the plumule peeping up, for then the seedlings are as sweet as young Peas. We should not mind sowing under cover the earliest crops, even with the ground so wet as it is now, and altering it to bring it into a nice, dry, friable condition before the plants are turned out, and then staking them as we go, for in that case the ground is left in such a healthy condition that the Peas generally thrive much better than those which have been longer in the ground. It is a serious matter, however, to do this with the general crops, as we did with most of them last season. Even the matter of watering them becomes serious, and there is a difficulty then in securing the usual luxuriance, and altogether the additional labour involved would soon equal in cost many yards of wire guards.

Treat garden Beans much in the same way as Peas.

Dwarf Kidney Beans must make room for a succeeding crop, the last just showing bloom, and the one before that bearing, and we have nice plants just ready to turn out. Now is the greatest strife of the season under glass—the great contest, resolving itself into whether such and such space shall be given to the useful or the ornamental.

Sowed more Celery on a slight hotbed covered with glass, and scattered over the bed a thin sowing of Cauliflower and Lettuces, which will be transplanted, or rather pricked out, before the Celery shows much.

Planted out strong plants of *Cucumbers* from six-inch pots, and singly, and used nothing but turfy loamy soil, well aired, with a little two-year-old cowdung. We examined the soil for fungus spawn, and rejected all in which there was a trace. On removing the soil lately from an old Cucumber-bed that did not quite please us, we found that there had been spawn in the little leaf mould used, and it had spread considerably in the soil. We have never found Cucumbers thrive well with such fungus matter in the soil. Wherever it is suspected a little quicklime should be added and frequently turned with it, but the whole should remain exposed until the lime has become quite mild. We have traced some of the ills that Cucumbers "are heir to" to the fungus matter in the soil, at least we think so, and only wish we could be more certain. We have advocated fermenting tree leaves for many purposes; but though it involves a little waste, it is safest to use them after they have been well heated, as the heat helps to send all crawling intruders to a distance, and to destroy the most of the fungus spawn. Even with that care we have found nasty spawn spreading through the leaves, and taking hold of and running thread-like through the soil; and then in some cases we have found the leaves of Cucumbers flag, fade, and rot, without any apparent cause; the stems would become soft and cankered, or split and gutter, and the smaller fibres would be soft and spongy, and rot with mildew. Instead of the old nostrums of many ingredients in a compost, we shall have to resort to simplicity more and more in soils, and many things besides. Though leaf mould is one of our most useful materials in a garden, we feel sure that if not decomposed and sweetened, and free from fungus, it often, especially in the last case, does great injury. For particular purposes, such as when used by the amateur for his favourite pot plants, it is a good plan to heat it well at a fireplace, or in or about an oven, and then place it in a dry, airy situation, and turn it frequently until it is thoroughly sweetened. All soils for in-door work will be much improved by this airing and sweetening.

All forced vegetables much the same as in former week's notices. Earthed down the fourth piece in the Mushroom-house. The first piece is still doing fairly, the second is in full bearing, from the third we shall not expect the Mushrooms to show for some weeks. The heat given off by these shallow succession-beds has been sufficient for the house, except when we had the severe frost, and we gave extra heat then chiefly because we wanted extra produce. We have often done this when we wanted a good supply for a certain time, though well knowing we should rather injure the continuous bearing of the bed. We were somewhat afraid we had thus put a sudden stop to the producing powers of the first bed; but after sweeping it all over, giving a little manure water, and a slight covering of hay, it has produced abundantly after a ten-days rest.

FRUIT GARDEN.

Besides pruning, nailing, &c., out of doors, and planting what should have been done in autumn, our chief work has been regulating and finding room for *Strawberry plants*. In our lean-to Peach-house, where the bloom is rejoicing in the snatches of sunshine, which house is about 11 feet wide, we have now four rows of Strawberries far apart from each other, and the shade of which will do little harm to the trees for some time. The highest suspended shelf has the pots set on turf reversed, and the grass from the edges of the turf has been twice clipped off, as otherwise from its hanging down it would give nearly as much shade as the pots. Besides, once or twice we have noticed this grass, from the extra stimulus to growth become very weak, and then it would be attacked by insects, and these would not stay on the grass. This does not often happen, but it is almost the only objection against using turf for this purpose, so far as its utility is concerned. Moss, too, is also very good, more especially if soaked some hours previously in hot lime water. Of course, we mean moss mostly fresh-collected, as, if it has been long stored up and dry, such precautions will not be needed. In its fresh-gathered state it is almost sure to have lots of slugs and snails, which though next to invisible to the eye, will soon show themselves when indulged with the higher temperature of hothouses or pits. Hence the propriety of soaking it in hot lime water. A little precaution often saves much trouble and expense.

ORNAMENTAL DEPARTMENT.

In addition to the general routine alluded to last week, the chief additional work has been inserting cuttings, potting Scarlet Pelargoniums in large pots for standing in verandahs in summer, giving them a little bottom heat after potting, and turning out and repotting a lot of *Caladiums*, placing them in small pots in the meantime, and where they will have a little bottom heat. We would have delayed this until the rhizomes had begun to push, but we wanted the room in which the large pots stood, and the pots, too, for other things. We have seen Caladiums do well where they were scarcely ever entirely at rest, such as when planted out on banks or rockeries, in plant-stoves. When grown in pots and allowed to go to rest as the leaves show signs of decay, two precautions are necessary for their safety: First, that the soil in which they are kept in the pots should neither be very wet nor yet dust dry, but in such a position as would be secured by the pots standing on a damp-

ish floor, and a little covering of moss over the pots, in which position the soil will remain in a kindly condition without any aid from the watering-pot, and the moss will also do much to maintain an equilibrium of moisture and of temperature; and, secondly, the temperature even with all this care should not be too low—it should seldom be below 55°, and should range between that and 60°. If kept dampish and in a lower temperature the rhizomes will be almost sure to become like a mass of soap. We have several times found them much shrivelled when kept hot and dry.—R. F.

COVENT GARDEN MARKET.—FEBRUARY 20.

THE Market remains steady, but there has been no improvement in the demand for any description of produce, consequently prices remain as last week, and we have no new feature to report. Arrivals of Potatoes are ample to meet the daily sales, both here and at the water side.

TRADE CATALOGUES RECEIVED.

William Rollisson & Sons, Tooting, London.—*Catalogue of Floricultural and Culinary Seeds.*

Mrs. Dixon, 48A, Moorgate Street, London, E.C.—*Select List of Kitchen Garden, Farm, and Flower Seeds.*

Sutton & Sons, Reading.—*Sutton's Farm Seed List.*

TO CORRESPONDENTS.

*** We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed *solely* to *The Editors of the Journal of Horticulture, &c.*, 171, *Fleet Street, London, E.C.*

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

N.B.—Many questions must remain unanswered until next week.

POTATO ROSS'S EARLY (*G. A.*) — Messrs. Lawson, nurserymen, Edinburgh, could tell you where it is purchasable.

CAMELLIA GRAFTING (*Dickson*).—April is a good time for the operation.

TRANSFORMATION OF PLANTS (*W. L. C. G.*).—Such changes as petals into calices, and these into leaves, with many other such transformations, constitute what has been dignified with the name of morphology. The changes arise from various causes; but, why is not easily explained. Twenty-eight postage stamps will entitle you to a copy, free by post, of "The Horticultural Directory for 1867."

SUCCULENTS (*C. J.*). — We cannot recommend florists or any other tradesman. If one cannot supply you, you must write to some other.

DRIP FROM ROOF OF STOVE (*S. E. H*).—The house must be kept excessively moist for moisture to drip from the rafters. You may safely discontinue the syringing at this season, and, indeed, at any time syringing fine-foliaged plants is not good for them, as the water hanging from the points and edges of the leaves is apt to cause brownness and decay. The only defect we are able to point out in the construction of your house consists in the lights or ventilators not fitting well, and letting in the rain, and as water drips from several parts of the glazing, we conclude that part of the house has been badly constructed. Perhaps the putty was bad and the laps of the panes of glass insufficient. No internal moisture, unless it arise from excessive sprinkling and syringing, will injure or destroy the foliage of the plants further than may be prevented by the careful admission of air, and reducing the amount of moisture within the house. The roof should be seen to, and the ventilators made more secure against rain.

RIVER BANK PLANTING (*T. W. R.*).—We know of nothing that would serve you except Cornus sanguinea and the different kinds of Willows.

PIGEON MANURE (*Idem*).—Pigeon-dung is an excellent manure, and may be used with advantage to all vegetables. It is very stimulating, and may therefore be of greater value to such as are of quick growth. We have used it with advantage for early Potatoes.

MISTLETOE SEED SOWING (*A Young Gardener*).—Directions are given at page 93 of our present Volume—the Number published on January 31st. It grows most readily on the Apple, but it succeeds also on the Pear, Hawthorn, Hazel, Maple, Lime, Elm, and Willow. It rarely is established on the Oak.

GREEN TURF FOR CAMELLIAS.—*H. E.* would be obliged by Mr. Fleming stating how it is that the grass in the fresh-cut turf does not grow in the pots.

LIQUID MANURE IN A STOVE (*H. M. G.*).—The ammoniacal vapours arising from guano water applied to the stages (2 ozs. to the gallon) would not injure the foliage of Orchids.

PELARGONIUMS (*A. & M.*).—*Castlemilk* is a silver-edged variety, the white edging broad and softly clouding far into the green disk. This is very peculiar, and so is the form of the leaf, if the specimens we have seen were of their usual form, for they were perfect cups, the under side of the leaf being the inner side of the cup.

BOILER HEATED BY KITCHEN FIRE (*E. B. B.*).—The common boiler at the back of a kitchen range will suit your purpose. Of course the more it is exposed to the fire the better. If your boiler is open you are aware that your pipes should neither be above nor below the boiler. One-inch-and-a-half pipes will be quite sufficient to convey the water from the boiler to the four-inch pipes in the house to be heated, which is 18 feet from the boiler; but in that case these small pipes must be encased in sawdust, &c., or means must be taken to prevent their losing heat in that 18 feet, as the smaller the pipe the more would it be cooled if exposed. See answer to "F. F."

HEATING A PROPAGATING-HOUSE (*R. B. N.*).—As your fine has to go 10 feet before entering the house, we think the fine passing below the bed will bear the heat, though not knowing of what the piping is, we are not so sure of its doing so as if it were made of brick in the usual way. If you were to have a small trough for water for the pipes below your bed, and openings from that into the atmosphere of the house, to be regulated by plugs, then we think you might dispense with the culvert "A," which would be much in the way. The other arrangements seem correct, except that you should have openings from the chamber below the front platform to let heat into the atmosphere of the house as needed.

FORCING ROSES, LILACS, DEUTZIAS, &C. (*E. Newton*).— In the house heated by hot water you may have in bloom a great variety of plants by keeping it at a temperature of from 50° to 55° at night, with a rise of 10° in dull days, and of 5° or 10° more during clear days. The plants should be syringed in the morning and evening, and a moderate amount of ventilation must be afforded. If your house is devoted to greenhouse plants you will do well to confine yourself to them; and by growing plenty of Chrysanthemums, which will continue in flower from October until January, and Primulas, with Camellias, Epacrises, Correas, Cyclamens, Monochætum ensiferum, and Coronilla glauca, which will succeed the Chrysanthemums, it may be kept gay. Also have bulbs, such as Crocuses, Tulips, Hyacinths, and Narcissus; Lilies of the Valley, Dielytra spectabilis, Deutzia gracilis, Weigela rosea, Lilacs, Philadelphus, and Roses, which from their strength and ripeness of wood are calculated to bloom early in January, assigning them a light and airy situation. The above, with the other plants that will be in flower, will keep the house gay, especially when Azaleas come in. Pyrus japonica in a pot does well gently forced, and nothing is finer than Rhododendrons.

PROTECTIVE NETTING FOR PEACH TREES (*B. W. Stannus*).—The netting you enclosed is a good protection for the blossoms of your Peach trees, but should be doubled, or in readiness to be doubled, in case of severe frost. It should be kept at the distance of a foot from the wall by poles placed with one end under the coping of the wall, and the other in the ground at 1 foot 6 inches from the wall. The netting need not reach so far as the bottom of the poles by 1 foot. The poles may be 3 or 4 feet apart, and the netting secured to them at top under the coping, and at bottom fastened to the stakes or poles, which need not be more than 2 inches square.

VINE BORDER (*Idem*).—It is not usual to have the borders shallower in front than where planted; so to construct them is decidedly wrong.

CHARCOAL FOR VINE BORDER (*E. G. D.*).—The charcoal you propose using in the formation of a Vine border may be employed with advantage in pieces from the size of a hen's egg to that of a walnut, or even of a pea. It is, as you say, very useful to keep the border sweet. The lumps are better than the dust.

HYACINTHS DONE BLOOMING (*Inquirer*).—After blooming they should be hardened off or kept beyond the reach of frost in an airy light situation. When all danger of frost is past they may be planted in the open ground, covering the crowns of the bulbs with 2 to 3 inches of soil. Those grown in water are of little or no value after blooming, and those forced in pots are not worth forcing a second time.

IVY FOR FERNERY (*Idem*).—The smaller varieties of Ivy do well in glass ferneries; indeed most kinds answer, and are very pretty climbing over rockwork.

Pampas Grass Frosted (*Hanley*).—The Pampas Grass, killed to the ground by the late severe frosts, should not be cut down until the end of April or beginning of May, when the withered and dead foliage may be removed. The plant should have a mulching all round it, which may be neatly pointed in when the old foliage is cut away. Copious waterings with liquid manure are advantageous during dry hot weather.

Early-flowering Rhododendrons (*Beta, a Subscriber*).—The kinds which bloom at this early season are practically worthless, being in most seasons injured by frost to a greater or less extent; but they are good for conservatory culture, or where protection is afforded. We know of no means of retarding their flowering. Pinching off the flower-buds would prevent their flowering in the following year.

Annuals for Bedding (*Idem*).—Annuals would have a good effect and assist you to fill your beds—for instance, you may have Perilla nankinensis in the centre of a bed, your pale yellow Calceolaria round it, and Lobelia erinus speciosa as an edging. If your beds are narrow we should plant them in match beds or pairs, as follows:—In the two outside beds a line of Cineraria maritima in the centre, with a band of Tom Thumb Scarlet Pelargonium on each side, edged with Cerastium tomentosum; the next two beds from the opposite sides inwards, Heliotrope, edged with Saponaria calabrica; the next two yellow Calceolaria, edged with Perilla nankinensis, pegged down and pinched, or Lobelia speciosa; the next two Pelargonium Cerise Unique, edged with Cerastium tomentosum or Saponaria calabrica alba; and the two adjoining beds Tagetes signata pumila, edged with Oxalis tropæoloides (corniculata rubra). Some of these are perennials, but sown early they bloom or have effective foliage in the first year. All, with the exception of the Saponaria, which should be sown where it is to remain, require the treatment of half-hardy annuals. If you do not like the above arrangement, or have not plants of the Heliotropes, Pelargoniums, and Calceolarias, you may have as half-hardy annuals the following:—Stocks New Large-flowering Ten-Week, interspersed with the autumnal-flowering, which flower late, or either separately. The Dwarf German Ten-Week Stocks are good; one or two beds of Stocks are fine. The Victoria Aster will furnish materials for a pair of beds. Viola cornuta will have a good effect as an edging; it is a perennial. Also Amaranthus melancholicus ruber for its foliage, Calceolaria scabiosæfolia, Phlox Drummondi, Petunia; and of hardy annuals double Sanvitalia procumbens, double Jacobæa, Tropæolum Tom Thumb Scarlet, yellow and crimson Beauty, Coreopsis marmorata nana, and C. nigra speciosa nana.

Caladium Culture (*A Novice*).—The compost may consist of equal parts of turfy loam and peat, one-third leaf mould, and one-sixth silver sand, and one-sixth pieces of charcoal about the size of a hazel nut, all well incorporated. It is desirable to afford a temperature of 65° at night, and from 75° to 85° by day, with air. The watering should be very moderate at first, but when in full growth the plants require very copious supplies of water, and they luxuriate in liquid manure. The rhizomes should be buried about an inch.

Lapageria rosea Seed Sowing (*W. H. M.*).—Sow the seeds in pots or pans in a compost of turfy peat two-thirds and loam one-third, with a free admixture of sand. The pot should be well drained. The surface being levelled, sow the seed, and cover with its own thickness of fine soil. Place the pots in a hotbed of 70°, and keep the soil moist. When the young plants are large enough to handle, pot them off, and grow them on in the hotbed for a time, or until established, then harden them off, and place them in a warm greenhouse. For training a plant in a pan the best form of trellis is that of an umbrella, but nearly flat like a table.

Sweet Alyssum for an Edging (*Inquirer*).—If the seeds be sown in the second week of April in a flat-bottomed shallow drill the plant will make a pretty edging, lasting until late in autumn. Unless the soil is light it is one of the latest of flowering annuals. In heavy soils the seed should not be sown later than the second week of April. Sow moderately thickly, and when the plants are an inch in height thin them out to an inch or an inch and a half apart. For a line 50 yards long we should think 2 ozs. of seed sufficient.

Burnen Turf (*Calcaria*).—The turf that has been burnt if not reduced to ashes but only charred, will form one of the best of composts for Pelargoniums, Fuchsias, and Cinerarias, if used in the proportion of two-thirds to one-third leaf mould; but if the turf was hard burned, then the roots would not run well in it, and accordingly it should not form the staple of the compost. We may state that we have used the charred sods which had covered a heap of charcoal in the proportion of one-third of the compost, and it answered admirably. We should give it a trial.

Preventing Heat Radiating from Hot-water Pipes (*F. F.*).—How do you manage to have the heat in your hot-water pipes up to 216°? The whitening of the pipes exposed will arrest radiation. If done with quicklime it will stand for a considerable time; but we would prefer doing it with white or light-coloured paint. No colour, however, will prevent the radiation of the heat, though it will lessen it. In addition, wrapping the pipes in bands of wool or flannel will help you much; but even that will be much inferior to placing boxes of wood—say 5½ inches square inside measure round the pipes, and packing them lightly with sawdust. We have seen pipes exposed to the open air used for heating premises at the distance of 40 feet thus encased in wood, but without thick sawdust, and an opening left from the funnel into the house to be heated, and thus the heat given off by the connecting piping was carried along into the premises to be heated.

Queensland (*Old Colonist*).—We shall be very much obliged by your proffered communication. We always keep in mind the wants of our colonists, and publish anything connected with the culture of the soil that we think will be useful to them. If any colonist will write to us for information we will spare no efforts to obtain it for him. The sprig you enclosed is usually called the Cape Gooseberry, Physalis pubescens. The following is our note on Schizostylis coccinea (Crimson Schizostylis:—"*Nat. ord.*, Iridaceæ. *Linn.*, Triandria Monogynia. Native of watery places in British Caffraria. Flowers crimson, blooming late in autumn." A drawing of it is in the "Botanical Magazine" for 1864, t. 5422.

Primulas Diseased (*W.*).—They are indeed in a miserable plight. The roots must be nearly destroyed, either by vermin, or over-watering, or unsuitable soil. As we have no information on which to found an opinion we cannot suggest a remedy.

Name of Fruit (*Brassica*).—Your Apple No. 2 is Hoary Morning.

Names of Plants (*G. B.*).—Hardenbergia Comptoniana. (*Sophia*).—Polystichum angulare, not uncommon in the south and west of England. (*J. H. C.*).—1, Asplenium flaccidum; 2, A. umbrosum; 3, Adiantum tenerum; 4, A. hispidulum; 5, Acacia undulata; 6, Cypripedium insigne. (*G. M.*).—It is impossible to identify plants from sprigs of leaves. (*Dickson*).—Cephalotaxus Fortuni.

METEOROLOGICAL OBSERVATIONS in the Suburbs of London for the Week ending February 19th.

Date.	Barometer.		Thermometer. Air.		Thermometer. Earth.		Wind.	Rain in inches.	General Remarks.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

ROYAL AGRICULTURAL SOCIETY'S POULTRY SHOW.

We have great pleasure in calling the attention of our readers to the liberal prize list offered by the Royal Agricultural Society of England, at their meeting in July at Bury St. Edmunds. We trust it will be responded to by the amateurs of the United Kingdom. We know that if such be the case, the Show will be gladly continued by the Council; but if the poultry world be but badly represented, it cannot be expected that a Society such as this should be content with a small display. The list of prizes amounts to £206. They are chiefly offered to the breeds most kept by, or most likely to be profitable to, those engaged in agriculture. For the first time a separate class is offered for Houdans, and numerous prizes for Turkeys and Geese. We hope Norfolk, Suffolk, and Cambridgeshire will respond to the call, and that numerous entries will justify the amounts offered. The rules are assimilated as nearly as possible to those of any other show, and sales are recognised and encouraged.

The only objection that can be raised is, that the time of year is unfavourable; but we do not think it by any means great, much less insuperable. We do not look for the brilliant plumage of March in July, but we have never seen the time when we could not pick out good pens in condition to exhibit. Forward chickens are also fit to show; and although there are no separate classes for them, yet it is stated in the printed instructions, that wherever chickens are shown the Judges will be requested to take especial note of them, allowing for age. There are sufficient prizes for all ages to share in the awards, and the entries do not close till the 1st of June.

We cannot help thinking this is a step in the right direction, and we heartily wish it full success. None can shut their eyes to the importance of poultry in the present day. It ceases to be an article of mere luxury, and is part of the food of the country. Four hundred millions of eggs are imported every year; France, Belgium, and Holland are ransacked for food. It is true Rabbits do not enter into the category of farm produce, but it is not less a fact that they are imported into Eng-

land by the "ton," and are sold by the stone at a price that averages no more than that of mutton. They are sent over skinned, denuded of ears and feet; these are turned to account as fur and as manure, the latter used for growing the food on which they are fed. This has become a large trade. All the country from Calais to Abbeville is scoured for poultry—fowls, Pigeons, and Turkeys. This has existed for years, and a man who some time since commenced dealing on a small scale, died a short time ago a wealthy man, and at the period of his death was turning £200,000 per year. It may be the large farmer of England will not take to poultry again, but it is very sure that there are many who can, and will if their attention be drawn to it. Cherbourg is giving its name to Geese that come over by many thousands, and wherever the trade has penetrated the supply of the English market is the aim and end of poultry-keeping. The inhabitants of those parts can only speak of the cheap days of poultry as a thing of the past. It should be remembered that the poultry imported is not of the highest quality, and not that which supplies the tables of our aristocracy and the wealthy. It is consumed by the middle and even the working classes. The importance of poultry is becoming appreciated by Ireland, and it is not an unusual thing for several tons of it to arrive in one day at market.

Hitherto all attempts have been wrongly taken; breeding on a very large scale is a mistake, if by the term we mean keeping thousands of hens on a few acres; enough cannot be had to make it a profit, but many of the thousands paid to foreigners for eggs, Pigeons, Fowls, Geese, and Turkeys might be kept at home, and help to meet rent-day or to eke out a scanty income. The supply that comes from abroad is not the produce of a few large establishments, but it is the collected stock of many homesteads. The same is done in our poultry counties, Surrey, Sussex, and Kent. The higgler goes round and collects. In the neighbourhood of commons many Geese are bred, but thousands more may be bred, and there is a sale for them as soon as they are fit to move. Poultry, like everything else, has increased in price, and those who have had good Turkeys for sale have sold them well. Hundreds who have neither the time nor the convenience for breeding chickens and fattening them can keep egg-producing fowls that never sit. The Royal Agricultural Society has made three classes for the new French breeds that belong to layers only. We are sure it has conferred a boon on the country, on agriculturists, and all who keep or consume poultry, and we hope it will find so many entries to compete for its prizes, that it will meet the success and reward it deserves.

BREEDING GAME FOWLS.

(*Continued from page* 76.)

Some breeders assert that in crossing, colour and form, or shape, are derived chiefly from the cock, and that size, vigour, and constitution come from the hen. I would not, however, give much for any breed cock that did not impart all qualities to his progeny in excess of the hens. The best breeders for the cock-pit always considered the cock as the "fountain head" of all the qualities. The best breeders think so still, I believe.

Game fowls being very hardy will thrive in the smallest runs and spaces. I have seen them in small yards 10 or 12 feet square, and in rooms and cellars only 8 or 10 feet square, and yet healthy. These were the Brown Reds, Dark Greys, and white-legged, wheaten-coloured, Black-breasted Reds. A good country grass run would, of course, have suited them much better. Manufacturing workmen and artisans in the large towns often keep them in these small spaces. This shows them to be of stronger constitution than any other poultry, and less subject to diseases than any.

As to crossing and mixing the different colours, I think that Piles and Red Duns cross best of all the different colours, both being of a light red colour. Reds will always spoil the colour of Greys, giving them a tinge of red and brown, but Greys do not spoil the Reds. The best coloured Duckwings are bred from the Dark Grey cross, though this spoils Dark Greys. It is well known to all good breeders, that crossing colours is very injudicious as a rule, all the best breeders liking each sort to be exactly alike both in shape and feather and in blood, and disliking all mongrel mixed colours and crosses.

Slates I have noticed make a very bad roofing for poultry-houses, for they admit both heat and cold too much, heating very quickly in the sun. Wooden sides to poultry-houses are also bad, admitting cold too much. The best poultry-houses are built of brick with the roof always of good thick tiles.

No other poultry should be allowed to roost with Game fowls; and 7 feet is not too high for perches for them, though any higher would be bad.—Newmarket.

CROSS-BRED FOWLS—MANGOLD WURTZEL FOR POULTRY.

I have been much surprised to find the cross between a sitting and a non-sitting breed objected to. Now, I have kept fowls for years, and have tried different breeds, and from experience I can safely say that such a cross is the very best for those who want plenty of eggs, and not much sitting. The cross I prefer (if I can manage it), is one between Spanish and Cochin-China; the pullets, crossed again with Golden-spangled Hamburgh, produce the very best layers possible.

I have eight pullets from these crosses. During the severe weather I had plenty of eggs, although not quite so many as were laid before the frost set in. I have not a good run for the fowls; they are confined to a yard into which not a gleam of sunshine enters from the middle of October to the middle of February. The eggs are large and very rich; the hens large, hardy, and tame.

Have any of your correspondents ever tried globe mangolds for their fowls during the winter months? I have them boiled soft and chopped with their meal. In the summer the hens have chicken rice boiled and mixed with meal and bran. I always use bran, and although many disapprove of it, I believe it helps to keep my hens in the excellent health they enjoy. As my hens are entirely dependant on me for their food, I could not afford to give them meal alone. They have during the day two feeds of oats scattered amongst the grass with which I supply them.—J. L.

NORTHERN POULTRY CLUB SHOW.

(*From a Correspondent.*)

The first annual Exhibition of Poultry, Pigeons, and Canaries, under the auspices of the Northern Poultry Club, was held on the 7th and 8th inst. in the Mechanics' Hall, Aberdeen, and must have been most gratifying to the Association. Its first Show cannot be pronounced other than a remarkably successful one, both as to the number of the birds exhibited and their quality, there being 244 pens of poultry, 57 of Pigeons, and 82 of Canaries, in all 383 entries, and in quality far surpassing any previously shown at Aberdeen.

The *Spanish* classes, which came first, were very superior, there being scarcely a pen that could be called at all inferior. Mr. Gray's birds were especially fine, as also the second-prize cock belonging to Mr. Macaulay. Of *Dorkings* there was a very excellent show, especially the hens, which were almost without an exception remarkably good. The cock belonging to Mr. Anderson, of Ruthven House, Meigle, a splendid bird, obtained the cup for the best cock in the Show. *Cochins* were a good class, but I think the judgment in this and the next class—*Brahmas*, was faulty, the first prizes for cocks being awarded to large, coarse, and rough-feathered birds in preference to birds much more handsome, better-shaped, and more even in colour. The second-prize Cochin cock was really a very fine bird, and should have been first. In the class for Brahma cocks (nineteen entries), there was a better show than I have seen for a long time; but I think the Judges committed a great mistake in passing over Mr. Jopp's splendid bird, and giving the first prize to a heavy, coarse-looking bird, very flat in the breast. In pairs of hens Mr. Jopp was first with magnificent birds, both as to colour and size, and well feathered. The *Game* birds were a large and very excellent class. Among cocks, John H. Wilson, Esq., St. Bees, took the first prize with a splendid Black Red, as fine a specimen of this kind as there has ever been shown in Aberdeen. Mr. Anderson was first for pairs of hens with a magnificent pen, and second with one little inferior. Pencilled *Hamburghs* were an admirable class; but in Spangled Hamburghs the cocks, with the exception of the first-prize one, were rather inferior, this being in fact the only inferior class in the Exhibition. The hens in the same class were highly meritorious, the first-prize pen being as fine a one as I have ever seen shown. Amongst *Houdans*, &c., B. C. Urquhart, Esq., of Meldrum, was first and second with really magnificent pens. Some other very good birds had no chance of a prize from want of condition. *Bantams* were a very good class, Mr. Anderson carrying off the principal prizes with exceedingly fine birds. The Aylesbury *Ducks* were a splendid show (twelve entries), not a bad one being amongst them.

There was an excellent show of *Pigeons*, and if I mention the names of Mr. R. Fulton, of London, E. E. M. Royds, Esq., and Joshua Fielding, jun., Esq., Rochdale, and Mr. Grant, of Edinburgh, as being prize-winners, the quality of the birds exhibited may be judged.

Canaries were an excellent show, all from local exhibitors, a Buff

Belgian cock belonging to J. D. S. Bennett, Esq., being the finest specimen seen for a long time.

Amongst other attractions, one of Mr. F. Schroder's Patent Incubators was exhibited, and received high commendation from many connoisseurs, as being the most perfect apparatus for hatching they had yet seen. The arrangements for the Show were admirable, and admirably carried out under the superintendence of the President, Mr. Jopp, Vice-President, Dr. White, and the Secretaries, Messrs. Hendry and Gray. All the birds were dispatched to their owners by the first trains on the morning after the Show.

The following are the principal awards:—

Silver cup for the greatest number of Prizes, J. Anderson, Meigle.

Spanish.—First and Third, F. W. G. Gray, Aberdeen. Second, J. Macaulay, Exchequer Office, Edinburgh. Highly Commended, J. Kerr, New Scone, Perth. Commended, Mrs. Stronach, Sunnybank, Aberdeen. *Hens.*—First, P. Brow, Perth. Second, F. W. G. Gray. Third, R. Macgregor, Sunnybower, Perth. Highly Commended, J. Macaulay.

Dorking (Any colour).—*Cock.*—First and Cup for best Cock shown, J. Anderson. Second, Mrs. King. Third, J. Wilson, M.D., Oldmeldrum. Highly Commended, J. Rae, Woodside, Craibstone; R. M'Gregor. Commended, W. M'Ritchie, Glasluw, New Pitsligo. *Hens.*—First, J. Gordon, Manar. Second, A. Smith, Bellelvie. Third, J. Anderson. Very Highly Commended, J. Allan, Crieff. Highly Commended, J. Gordon.

Cochin-China (Any colour).—*Cock.*—First, F. W. G. Gray. Second, W. Hendry, Aberdeen. Third, G. Edward. Highly Commended, B. C. Urquhart, Meldrum. Commended, Mrs. Carnegie, Redhall. *Hens.*—First, Mrs. Oswald, Dunnikier, Fife. Second, Mrs. Carnegie. Third, F. W. G. Gray. Highly Commended, Mrs. Blair, Aberdeen. Commended, F. W. G. Gray.

Brahma Pootra (Any colour).—*Cock.*—First, F. W. G. Gray. Second, K. Jopp. Third, J. Anderson. Highly Commended, J. Chalmers, Westburn. Commended, Mrs. Carnegie. *Hens.*—First and Third, K. Jopp. Second, F. W. G. Gray. Highly Commended, Mrs. Blair; K. Jopp.

Game (Any colour).—*Cock.*—First, J. H. Wilson, St. Bees, Cumberland. Second, J. M'Gregor. Third, T. Wright, Perth. Highly Commended, J. Anderson; J. Barrow, jun., Bradley Field, Kendal. *Hens.*—First and Second, J. Anderson. Third, T. Ogilvie, Aberdeen. Highly Commended, W. Hendry, Aberdeen. Commended, T. Ogilvie.

Hamburgh (Pencilled).—*Cock.*—First, J. Hay, jun., Aberdeen. Second, R. M'Gregor. Third, J. Anderson, Marischal College. Commended, J. Ness, St. Clartown, Fifeshire. *Hens.*—First, R. M'Gregor. Second, T. J. Harrison, Singleton Park, Kendal. Third, J. Still, Spital.

Hamburgh (Spangled).—*Cock.*—First, W. France, jun., Crieff. Second, J. Robertson, Kintore. Third, A. Copland, Kintore. Highly Commended, Mrs. Brown, Abercairney, Creiff. *Hens.*—First, W. France, jun. Second, Mrs. Brown. Third, A. Copland. Highly Commended, J. Robertson, Kintore. Commended, J. F. Loversidge, Newark, Notts.

Polands (Any colour).—First, W. M'Intosh, Nigg. Second, J. Robertson. Third, G. Edward.

Houdan, La Flèche or Crève Cœur.—First and Second, B. C. Urquhart. Third, W. R. Park, Abbot's Meadow, Melrose.

Any other Variety.—Prize, W. M'Intosh.

Game Bantams.—*Cock.*—First, J. Anderson. Second, R. M'Gregor. Third, W. Mabon, Castlegate, Jedburgh. Commended, W. Bearpark, Ainderby Steeple, Northallerton.

Game Bantams.—First, J. Anderson. Second, J. Hay, Aberdeen. Third, R. M'Gregor. Highly Commended, W. H. Butcher, Preston; Master W. H. Pople, Perth.

Bantams (Any other variety) —First, J. D. Skene, Aberdeen. Second, Master W. H. Pople. Third, J. Clark, Fochabers.

Ducks (Aylesbury).—First, A. Haggart, Leslie, Fifeshire. Second, J. Allan. Third, Mrs. Carnegie. Highly Commended, A. Farquhar, Elsick, Stonehaven. Commended, J. Robertson, Kintore.

Ducks (Any other variety).—First and Third, J. Anderson. Second, A. Farquhar. Highly Commended, A. Farquhar.

Turkeys.—First and Second, Mrs. Carnegie. Third, B. C. Urquhart.

Geese.—First, G. Edward. Second and Third, W. M'Intosh.

PIGEONS.

Silver Medal for the best single Pigeon.—E. E. M. Royds, Greenhill, Rochdale.

Silver Medal for the best pair of Pigeons.—R. Fulton, Deptford, London.

Extra Silver Medal.—E. E. M. Royds, for First Prize pair of Jacobins, as the best pair in the Show.

Pouters.—First, J. Grant, Edinburgh. Second, R. Fulton.

Carriers.—First and Second, E. E. M. Royds.

Tumblers (Almond).—First, J. Baillie, Bellevue, Aberdeen. Second, Thomsen, Kendal.

Tumblers (Any other colour).—First, J. Baillie. Second, R. Fulton.

Fantails.—First, J. Grant, Edinburgh. Second, J. Rae, Guestrow, Aberdeen.

Jacobins.—First, E. E. M. Royds. Second, R. Fulton.

Turbits and Owls.—First, R. Thomson. Second, J. Grant.

Any other Variety.—First, R. Thomson. Second, J. Rae.

CANARIES.

A handsome subscription Silver medal for the best Belgian Canary.—J. D. S. Bennett, Aberdeen.

A Bronze medal, for the best Don Scotch, presented by Mr. M'Donald, Lodge Walk.—J. Ross, Gallowgate

A Subscription Bronze medal for the best bird of any other variety.—J. Hunter, Bellevue, Hardgate, Aberdeen.

1 Stone of Canary seed to the best Flecked Belgian, presented, by J. Roy, jun, Esq.,—J. Ross.

Belgian (Yellow).—*Cocks.*—Prize, A. Barnett. *Hens.*—Prize, J. Wishart.

Belgian (Buff).—*Cock.*—Prize, J. D. S. Bennet. *Hens.*—Prize, J. D. S. Bennet.

Belgian (Flecked).—*Cock.*—Prize, H. Mackie. *Hens.*—Prize, J. Ross.

Don Scotch Fancy.—*Cocks.*—Prize, J. Ross. *Hens.*—Prize, J. Ross.

Any other Variety.—*Cocks.*—Prize, Miss J. Allan. *Hens.*—Prize, Mrs. Browning.

Mules.—*Cocks*—Prize, J. Hunter.

Goldfinch or other British Bird.—*Cock.*—Prize, J. Wishart.

The Judges were—For *Poultry*, D. Brown, Esq., Perth, and Geo. Taylor, Esq., Inverness; for *Pigeons*, Mr. Brown and Mr. Cruickshank; and *Canaries*, Mr. Mitchell, of Perth.

NANTWICH POULTRY AND PIGEON SHOW.

The eighth annual Exhibition at Nantwich was held on the 8th and 9th inst., and a most excellent meeting it proved to be, particularly when the late period of the Show is taken into account, and the drawback to competition arising from the closely approaching breeding season. The Committee are a body of gentlemen of great self-denial, and unusually persevering, and in this alone, no doubt, resides the secret of their continued success. During the day merry peals were rung from the fine old church, vehicles of all kinds came laden with their fair occupants, and the attendance was exceedingly good. The Nantwich Town Hall is a most excellent place for a poultry show, and the arrangements for the comfort of the birds were really unexceptionable. A very uncommon but most useful feature was introduced into the catalogue—viz., a reference at the heading of the classes stating the part of the Exhibition-room devoted to each particular class. It saves much time, and really preserves much order among visitors, always anxious as speedily as possible to see particular favourites. This, we believe, was an original suggestion of the indefatigable Honorary Secretary, Mr. Edwin Rhodes.

Neither as to numbers nor quality were the *Spanish* fowls so good as on some former occasions; but the Grey *Dorkings* made most ample amends for this shortcoming. There were also some very capital White Dorkings, but in a general competition they rarely can succeed in taking prizes. The Aylesbury *Ducks* were remarkably good, but the Rouens were considerably below the generally accepted standard. In proof of the unusual excellence of the class for *Turkeys*, the first-prize pen took also the silver cup for the best pen of poultry exhibited. They weighed 40 lbs. the pair; and even a pen only so high in the scale as a high commendation turned the balance at 39 lbs., so great was the competition. The Buff *Cochins* were of unusual excellence. the Hon. Mrs. Sugden most liberally giving a silver cup for the best pen. In these classes not unfrequently a very light Silver Cinnamon hen was exhibited with a rich Buff cock. Such disparity of colour in the same pen is always inadmissible. The pair of Buff Cochin pullets, the cup-winners for Mr. Mapplebeck, of Birmingham, were far better than we usually meet with at any show. White Cochins were well shown. In the *Game* fowl classes, as usual at Nantwich, were to be found a long succession of rivals of the most extraordinary merit. We regretted, however, to find many adult birds entered as cockerels; and as to filing and glass-papering the spurs to make them appear like those of birds of the season, it might truly be said to be almost the order of the day. A few were thus treated very artistically; others were absolutely rasped off, until the core of the spur was entirely exposed; and one bird, at least two years old, had his spurs actually sawn clean off, as though for the cock-pit. Provision, we are told, will be made in future years against this disreputable attempt at imposition by the entire prohibition of the use of the file to the spurs of any cockerel, and very properly so. Brown Reds were, as usual in this district, the best variety of Game fowls shown; though in justice we must particularly allude to the first-prize pair of Game pullets—in one word, they were the best pair of Red Piles we have ever yet met with. Mr. Heath, of Nantwich, exhibited some extraordinary Silver-spangled *Polands*, a breed for which that gentleman's name has become famous.

The *Pigeons* were a very popular part of the Show, Carriers, Short-faced Tumblers, Fantails, Barbs, and Trumpeters constituting the cream of the collection.

This Show now seems fairly established, and it is most gratifying to record a favourable additional balance on the right side of the accounts from year to year. May this prosperity continue.

[We published the prize list last week.]

NEW PUBLICATION.

A Few Observations on the Breeding of Trumpeter Pigeons. By Thomas Rule. Durham: J. H. Veitch. Pp. 4.

An increasing minority of our readers are ladies and gentlemen who take delight in fancy Pigeons. Residents both in town and country have become gradually awake to the beauty, highly ornamental character, and very interesting nature of these birds; probably the better engravings which we see now-a-days of fancy Pigeons have something to do with this change in their favour, for had the poor birds been as ugly as the pictures in the old Pigeon books, and even in some modern ones, nobody would have cared to keep them; but the pencil of a Harrison Weir has at length done the fancy Pigeon full justice. At many a villa fowls cannot be kept; but Pigeons, never annoying a neighbour or injuring a garden, can always have a home, and a collection of true-bred birds, either hover-

ing in the air, sunning themselves on the house, or promenading the bright, clean gravel, is attractive even to those who do not understand them, for the eye is pleased by their variety of form and feather; while to the fancier the pairing the adult birds, the watching for beauties in the young, and marking the various properties in all, form unceasing sources of interest and amusement. As yet there have been few Pigeon writers, and the most accurate, Mr. Brent, must, alas! be spoken of as the late; but I do not doubt there will be plenty of writers on this subject now that many well-educated people have become Pigeon-fanciers.

I have been led to make these observations from the nature of the subject rather than from the bulk of the publication at the head of this paper, which contains but four pages, one of them being the title-page; but a writer who speaks in the following modest manner disarms criticism. "I have given," says Mr. Rule, "all the information I can on the present subject, and hope it will not be taken in a wrong light, for it is not with any arrogant feeling or presumptuous thoughts that I have dared to give these few expressions, but merely to give to the less-experienced what I have learnt by a few years of close and attentive observation." I will not say more critically than that the pamphlet is not very well expressed, and the price, marked in ink on the copy before me—viz., *2s. 6d.*, must surely be a mistake.

In regard to Trumpeter Pigeons, I had recently an opportunity of seeing some birds, brought from Egypt by a gentleman long resident there, and called by him Egyptian Pigeons; but they were to all intents and purposes White Trumpeters, though not quite equal to our best fancy birds. This fact confirms the late Mr. Brent's observation, that "Trumpeters are of Egyptian origin." It is a good plan, especially for those fanciers who have not much space, to devote themselves to one variety, and try to bring it to perfection, or at least to test its capabilities of improvement. Probably Mr. Rule has done this with the Trumpeter: hence his pamphlet. In the estimation of some fanciers the Trumpeter holds a high place. I have known, both formerly and in recent years, gentlemen who were life-long Trumpeter-fanciers, so that there must be much in the breed to repay such regard, pains, and attention. Indeed, the Trumpeter, if well-bred and kept clean in feather and feet (he is the very bird for the country), is a noble-looking fellow. His size and feather helmet, moustache, and jack boots mark him out as a cavalier. He has something to say also for antiquity of race, as he is mentioned by our oldest writers, and always ranked by them among the better Toys.

Mr. Rule has studied his birds well, and what he says in regard to breeding Mottles, which are perhaps the handsomest, appears likely to be correct. In his chapter "On Laying" the cure for apparently barren hens, which has been known at any rate since the days of Windus (1802), and has been copied by Eaton, Mr. Rule appears to have found correct. The non-advisability of allowing Trumpeters the free use of the bath is a good hint, and the "Notes on Food and Nesting" are worth remembering.

In conclusion, I would observe that if fanciers of special varieties of Pigeons would year by year note their failures and success in their pocket-books, and send their notes to this Journal, they would secure a greater number of readers than any one publishing a small pamphlet, and they would also serve better the cause of the fancy generally. Some varieties may yet be improved, the best fanciers may yet have something to learn, the beginner much. It seems pretty evident that we shall soon have a Pigeon show attached to every poultry show, and no birds are better suited to be ladies' pets than fancy Pigeons. I will not say more of Mr. Rule's pamphlet as I am not a Trumpeter!—Wiltshire Rector.

WELSH RABBITS.

In your notice of my "Instantaneous Reference Guide for Poultry, Pigeons, and Rabbits," you appear to doubt the existence of a breed of Rabbits stated in the Guide as Welsh. I beg to inform you and others in doubt that those Rabbits known as Welsh in my neighbourhood have long black coats, dark eyes, and are of much the same shape and size as the common tame Rabbit. It is certain they are a distinct breed, although some persons might think them Angoras from having long coats; but this is an error, for Angoras to be pure must be perfectly white, and have shorter ears. I do not consider them handsome, although they prove an agreeable contrast to the Angora, which is the prettiest of Rabbits.—David P. Gooding.

FOUL BROOD.

While making these remarks I have no desire to re-kindle the ashes of the once celebrated foul-brood controversy, but solely to contribute to the stock of general information, with the view of assisting such of your correspondents as the estimable "R. S.," who, instead of carping, methodically applies himself to the task of endeavouring to discover the cause and cure of a malady at once the most mysterious and destructive which can affect the well-being of our interesting little favourites—and his efforts in this direction are beyond all praise.

First of all I may relate a curious circumstance connected with this subject.

It is now some time since I chanced to receive a visit from a stranger bee-keeper, from a considerable distance, who had come, on the recommendation of a mutual friend, to inspect my apiary and have a second look at those "new foreign bees," as he styled the Italians. His wishes in this respect having been duly gratified, we adjourned to the house; and my new friend, although a plain man, I found shrewd and thoroughly intelligent, quite an enthusiast in bee-keeping, as his father had been before him, and, I subsequently learned, no mean authority in his own district, from his sound judgment and integrity, being by common consent the favourite judge at all honey shows far and near. On the first favourable opening of the somewhat lengthened but most interesting discussion which followed, I asked if ever he had met with foul brood. "Oh, yes, often enough," if it was "back gaun brood" I meant; and then, having been fairly started on the subject, there followed a long list of illustrations, brought to a stand I imagined by my putting the rather pertinent question, What was its cause? Oh, for the graphic pen of our worthy chaplain, "Wiltshire Rector," to depict, in solemn conclave met, the numerous band of correspondents and readers of the bee corner of "our Journal" to discuss the origin of this dire malady! the derisive shout that must have arisen from your talented contributor Mr. Lowe and his disciples the chillists, on hearing his ready reply, that instead of their pet theory of experimenting with subsequent chill, it altogether arose from "jist overheating!" How came he to this conclusion? was followed by an array of instances, terminating with, "Take the first time I saw these foreign bees of yours," and he proceeded to relate how he, along with a few friends and neighbours of a gentleman in his part of the country, had been invited to witness a first flight of Italians just arrived—not any small artificial swarm from the experimental apiary of our good friend "A Devonshire Bee-keeper," in some abominable compound bar-and-frame hive, but, on the contrary, direct from their native mountains, a teeming population in an orthodox common straw skep. The bees having been liberated, and the first few emerging and taking wing having been duly admired, the company proceeded to the house to share their host's hospitality, but my informant (I have not a doubt the most interested of the group), speedily stole back to the garden to feast his eyes on the glittering foreigners, and threw quite a gloom over the company by returning in a short time, and telling their owner his new bees would do him no good from "back gaun brood," as they were fairly overheated, streaming in masses over the board. And had his prophecy been verified? I asked—he was certain it would, but had never been there since.

It so happened last spring that I received a communication from a most experienced apiarian, and amongst the incidents of his apiary he narrated the loss of a very precious Italian queen, and to replace which he had taken a trip to try and purchase the queen of an imported colony badly infected with foul brood, but had arrived too late, as on examination he found that the queen as well as her entire subjects were numbered with the dead. Could it be possible? I at once wrote to my friend, and found that by one of those strange coincidences we sometimes meet with, this was the identical colony whose "welcome home" the honey judge had attended.

I was accidentally enabled to test the point for myself last summer as follows:—To prevent a swarm from a very populous and most healthy Italian colony, I transferred a few frames along with the queen to an empty hive, and dispatched it to the outlying apiary more than a mile away; and so rapidly had the population increased, that my man on carrying it home some weeks afterwards, thinking it unnecessary to take a

cheese-cloth with him, merely satisfied himself by wedging it up, but discovered his mistake on arrival, for he found the honey streaming over the board, and on raising the hive a pitiful sight presented itself, several hundreds of bees being suffocated and drowned on the board. A clean one was at once substituted, and with some anxiety I searched for and was pleased to find the queen uninjured, and while so employed did not fail to observe the immense masses of maturing brood and its perfectly healthy condition, not even one suspicious cell to be seen. This was most satisfactory, and I closed the hive, thinking a few days would repair the loss of bees, which could well be spared, and that it would soon be necessary to super and nadir to save swarming. Such were my cogitations, when there arose to my mind the stalwart form of my prophetic friend, pronouncing this clearly a case of overheating. The colony remained undisturbed for several weeks, without requiring additional room, and it was with fear and trembling I proceeded to examine it; but how woefully was the picture which previously presented itself now reversed! Here were perforated cell-covers in abundance, with the too familiar slimy decaying embryos—in short, unmistakably foul-brooded.

A subsequent examination towards the end of the season showed a manifest improvement in the stock, both as regards population and the clearing out of foul cells, a proceeding I never before witnessed, save in a straw square frame hive the preceding season, as recorded in No. 238, and I have now no doubt that that outbreak, like the above, originated solely from overheating. Some few foul cells still remaining, I thought it prudent to put the bees through the purgatorial process, and joined them to an adjoining stock, as I had done at the end of the preceding season those of the square straw hive above alluded to; only in that case, the population being still larger, I gave them the entire works of a vacated black colony, and they prospered exceedingly, throwing two fine swarms last summer, besides at its close outweighing any swarming stock I possessed. The other colony referred to in the above Number of the Journal was a particularly strong one, in a set of Stewarton boxes, the only one bred of an infected Devon stock which had escaped contamination, and although the population was enormous, and yielded me five beautiful octagon supers, the disease had made such rapid progress by the spring that I appropriated its contents, and saved the population in a clean hive, which subsequently prospered.

My experience forces on me the conviction that overheating rather than any amount of experimenting and chill, induces this most mysterious malady, and as confirmatory of this conviction, I quite agree with what your correspondent, "A Lanarkshire Bee-keeper," says as to its showing itself so much more readily in warm weather; still there is no doubt it can be communicated by infection at any time, in which case it assumes a much more virulent type. As to the harmlessness of chill, I had a good illustration in a large mahogany unicomb observatory hive, stocked late last season with the frames and population of a strong Italian hive. Cold nights soon setting in, the bees drew up off the brood, abandoning frame after frame, receding yet upwards till I removed them back to their original hive in the beginning of winter, making then a thorough scrutiny; and while there was plenty of chilled brood, I did not observe one foul cell.

A leading Ayrshire bee-keeper, long a severe sufferer from foul brood, wrote me lately, that by thoroughly ventilating his entire stock during the last summer, as recommended by the Rev. L. L. Langstroth for winter practice, he has seen less of his old enemy than for many a day.

The recent introduction of frame hives, instead of originating has rather been the means of calling attention to this disease, which exists in cottagers' hives kept exclusively on the swarming system, to an extent little imagined. My assistant was stung into the belief that the irascible Italians and their artificial propagation were the sole cause of this fell blight on our previously flourishing apiary, but had his faith thoroughly shaken on receiving leave of absence to visit his father, to whom, doubtless, he recounted many feats of apiarian valour. The old cottager agreed to submit a large stock to the driving process, otherwise doomed to the brimstone-pit. It had thrown two good swarms during the summer and had never been raised once from the board since it was set down a swarm, and yet on his return he told me this stock contained a mass of foul brood as compared to which our worst cases were but trifling.

Last autumn I had an opportunity of inspecting an apiary, with one exception the largest I had seen, kept altogether in common swarming hives, and while awaiting the coming of the party in charge, was not a little tickled at the mode of feeding, which fairly outrivalled the "*Times* Bee-master's" plan. On the landing-boards of about a score of hives were placed pieces of broken combs for the bees to clean out, and in every instance were present evidences of the certain existence of foul brood, doubtless weak stocks that had been broken up and their contents thus disposed of. The feeder on his arrival was in happy ignorance of either "foul" or "back-gaun brood." Not so, however, must have been their old master, then on his death-bed, otherwise his stock could not have multiplied to such an extent.—A Renfrewshire Bee-keeper.

OUR LETTER BOX.

Eggs Ill-flavoured (*Mitcham*).—The disagreeable flavour arises probably from some plant the fowls eat in your garden. If the "market sweepings" contain much of peas and beans, these and the buckwheat together would be very liable to impart a rank flavour to the eggs. Do not omit the calcined oyster-shells.

Golden-spangled Hamburgh Cockerels Dying (*T. H. R.*).—We have no doubt you may attribute the loss of your Hamburghs to the snow. We can only answer your question by another: How is it that in fine weather, and with everything in their favour, the deaths among Crève Cœurs and La Flèches are seven cocks to a hen? There are certain things more fatal to cocks than hens. In your case the birds wanted the best stimulant you could give. Ale, wine, or brandy and water would have saved them. Their combs were frosted, and would have perished away.

Fowls for Damp Yard (*Lady Barn*).—Brahma Pootra, Cochin, and Houdan are all adapted for you. When you have young chickens feed them well on bread steeped in ale; let them have ale to drink, and if that is not enough, let them have camphor enough in their water to make it into camphor julep. By adopting this plan you will rear your chickens; but remember that either naturally or artificially they must have dust to bask and bathe in.

Brahma Pootras (*J. R. B.*).—Our experience does not agree with yours We do not find Brahmas eat according to their bulk. It is easy to test their consumption if you have them in confinement. Weigh or measure all the food they consume, see what it amounts to in bulk and money. We know only three breeds that bear confinement as well as Brahmas —Cochin-Chinas, Spanish, and Houdans.

Sick Fowls (*Cottager's Wife*).—Your fowls have access to something that disagrees with them. If they are in confinement, give them their liberty. If they are not, clean out all their places thoroughly, remove the sickly birds, and feed only on bread or ground oats steeped in strong beer. Let them have little water only three times per day, and none by them. Feed in very small quantities five times per day, and let them have fresh mould and gravel.

Lame Ducks (*M. C. A.*).—Keep your Ducks away from all water till they are cured. Give them oats in a shallow vessel. Cover the bottom of it with a sod of grass, and put water enough to cover it all.

Eggs of Dorking Pullet (*J. C. B.*).—The first eggs are as likely to be fertile as those later laid.

Flooring for Poultry-House (*A. O., Finchley*).—The following extract from "The Poultry Book," which you can have free by post from our office for 7*s.* 10*d.*, will meet your case:—"Bricks or pavements of any kind we regard as the worst of all materials for the floor; they retain moisture, whether atmospheric or arising from insufficient drainage; and thus the temperature is kept low when warmth is most essential, and disease too often follows, especially rheumatic attacks of the feet and legs. The flooring of a poultry-house should be of dry gravel, and quite loose to the depth of 2 or 3 inches—nothing can then adhere to it; and it is neither necessary nor right to sweep the floor of a poultry-house. A long birch or heath broom may be drawn lightly over the surface. It will remove everything that offends, but if turned over with a spade twice or thrice weekly, the earth deodorises the dung and becomes a good fertiliser in the course of a few months, and has then to be removed and replaced by fresh earth. A mixture of gravel and coal ashes makes an excellent flooring, and in which the fowls delight to busk."

Canary with Inflamed Skin (*J. Bisset*).—Are you sure there are no insects on the bird? If there are, dust him with flowers of sulphur thoroughly down to the roots of the feathers. Give a little maw seed once a-day, and let him have a bath daily.

Dimensions of Entrance and Box for Fantail Pigeons (*J. G.*).—If the question refers to a box nailed outside a wall, the entrance must be no larger than ordinary, or the rain would enter. As to the inside, it should be 14 inches square, as the pair would probably sleep in it, as well as have their nest in it. If, as is more probable, the question refers to nesting-places inside a loft, we have them 10 inches square for Tumblers, but some specially made for Fantails a foot square, quite open in front, except a bar about 3 inches high, in order to keep the nest in. By this size and arrangement the tails of the birds are uninjured. For a separate box in a loft a tea-chest does well enough, having a square nest made in one corner by two bricks meeting the back and side of the box. If there be a close front the door should be wide enough to admit of ingress and egress without crushing the fine expanded tail.

Boxes for Hives (*Q.*).—Our reply to "B." in last week's Journal should have been qualified by the statement that the "boxes" referred to were circular in form. Square boxes of 16 inches diameter would in our opinion be too large for bee hives.

Feeding Bees in Spring (*W. D. A.*).—We have already commenced feeding such of our stocks as require it, selecting mild days for the purpose Honey rendered fluid by being warmed and diluted with a little water is perhaps the best food; but we find simple syrup made of lump sugar, in the proportions of three parts sugar to two of water, by weight, answer every purpose.

WEEKLY CALENDAR.

From observations taken near London during the last forty years, the average day temperature of the week is 49.1°; and its night temperature 32.9°. The greatest heat was 70°, on the 4th, 1860; and the lowest cold 14°, on the 3rd, 1862. The greatest fall of rain was 0.81 inch.

CULTURE OF ROSES IN POTS IN GREENHOUSES.

THE best Roses for greenhouse culture are the finer varieties of the China and Tea-scented, the latter, especially, on account of their peculiar and delightful fragrance; but the Bourbons and Hybrid Perpetuals must be included. The following varieties I have found good:—

China.—Madame Bréon, Mrs. Bosanquet, Triomphe de Gand, Prince Charles, Henri Cinq, La Séduisante, Infidélités de Lisette, Louis Philippe, Napoleon, Clara Sylvain (generally classed with the Tea-scented), and Fabvier.

Tea-scented.—Goubault, Homère, Devoniensis, Abricoté, Buret, Adam, Barillet-Deschamps, Comte de Paris, Elise Sauvage, Caroline, Le Caméléon, Lays, Madame Bravy, Madame Maurin, Madame J. Halphen, Safrano, Victoire, Souvenir d'un Ami, Niphetos, Madame William, Maréchal Niel, and the finest scented of all Teas, the original of this family, Rosa indica odorata.

Bourbons.—Souvenir de Malmaison, Baron Gonella, Acidalie, Queen of the Bourbons, Emotion, Marquis de Balbiano, Reveil, Vorace, Sonchet, Rev. H. Dombrain, Louise Margottin, and Catherine Guillot.

The *Hybrid Perpetuals*, not to be overlooked, are Lord Macaulay, Lord Clyde, John Hopper, Lord Palmerston, Duc de Cazes, Duc de Rohan, François Lacharme, Gloire de Santenay, Charles Lefebvre, Caroline de Sansal, Madame Furtado, Duchesse de Morny, Madame Alfred de Rougemont, Madame Boutin, Louise Magnan, Louis XIV., Senateur Vaisse, Pierre Notting, Monte Christo, Virginale, William Griffiths, Comte de Nanteuil, Maréchal Vaillant, Madame Vidot, Baronne Pelletan de Kinkelin, Alfred de Rougemont, and Prince Léon.

All the above are good Roses, and, for greenhouse culture, should be on their own roots. Most, if not all, of the kinds named are kept in stock by our principal nurserymen in 24's or six-inch pots, of a size fit for this mode of culture, the cultivator being thereby saved a year in the preparation of the plants. Those, however, who wish to prepare their own plants should procure them in spring, not later than May, and if in small pots, as they usually are, they may be at once placed in pots 6 inches in diameter, in a compost of loam and leaf mould in equal parts, with a free admixture of sharp sand amounting to about one-sixth of the whole. The pots should be drained to one-third their depth with crocks, and in potting the ball should be gently pressed to loosen it, which is desirable.

After potting, the plants should have a good watering, and be set on slates or a hard bottom in an open, warm, sunny situation. The intervals between the pots should be filled with ashes; in other words, the pots should be plunged to the rim. The plants should be frequently syringed, especially in the evenings of hot days, and well watered at the root, taking care not to saturate the soil or make it sour through repeated waterings when it is already wet, and dryness must be equally guarded against, extremes of either being injurious. All flower-buds as they show are to be pinched off between the nails of the finger and thumb, and any strong shoot stopped at the eighth leaf. The pots should be occasionally lifted to see that the roots are not coming through, and if they are rub them off before they make any great progress.

Towards November the pots should be lifted and plunged in coal ashes in a cold pit or frame; the watering, being discontinued after September, is not to be renewed on the removal of the plants to the pit, but they are to be kept dry, and to have air whenever the external atmosphere is mild, also protection from rain and frost. Where the frame or pit accommodation is limited the Perpetuals and Bourbons may remain out of doors in a sheltered sunny situation, affording them the protection of a mat or other covering during very severe frost. Tea-scented and China Roses, however, must either have the protection of a frame or be placed at once in the greenhouse, which is anything but desirable, as the space which they there fill can be much better occupied with Chrysanthemums and other plants. Should there be a light and airy cool house it would be well to place them all in it, and if the weather prove severe a little hay should be packed round the pots, and may be spread over the shoots, taking care to remove it after the severe weather.

Early in February the plants may be taken into the greenhouse, the pots having been previously washed clean, and the drainage made good if defective, as no plant will thrive in a badly-drained soil. The surface of the soil in the pots should also be stirred, and if green, replaced with fresh. The plants may then be pruned. The pruning of the China and Tea-scented kinds should consist in moderately cutting out the very weak shoots, and doing little more than shortening those of moderate growth, so as to form a compact bush. The Bourbons and Perpetuals should be cut in—the very strong shoots to four, the strong to three, and the moderately strong to two eyes, and the weak cut clean out, unless a shoot be wanted in a particular place, when a weak shoot may be cut back to one eye. If tall plants are wanted, any of the Tea-scented or China varieties that have made good growths may have a neat stick or stake placed in the centre of the pot, and the strongest of the shoots tied to it, the others being shortened to different heights, that tied to the stake to have merely its end taken off. The plants must be placed as near the glass as their growth allows, and between it and them no creepers or other plants must be tolerated. They cannot have too much light, it is easy to shade them when in bloom, and the position should be airy. The temperature need not be altered to suit them, as that of a greenhouse is admirably adapted to their requirements. Due regard must be paid to watering them, avoiding extremes either way, and yet it is as well to let the soil become rather dry, and then afford a

good supply, and not dribblets, which, if the soil is dry, do not reach the bottom of the pot, or, if it is wet, only serve to saturate it the more. At first moderate supplies of water will suffice, but when the foliage has become developed it will be required in abundance. Syringing should be practised morning and evening, except in cold and dull weather, when once a-day, and in the morning, will suffice, and it should be continued until the flower-buds show colour.

After blooming, which will be in June, the plants should be removed from the greenhouse, and must be carried to the potting-bench, and repotted forthwith. If the cultivator does not wish for large plants he will merely cut back the roots a little, so that the pot will hold a little fresh soil, the old pot being clean-washed and again used. Varieties of compact growth will, of course, be selected for this purpose—small plants that do not take up much room, and the best are the small-growing Tea and China Roses. The others may have pots 9 inches in diameter, which are large enough, and not too large for holding sufficient soil for a good and yet not ungainly specimen. The pots should be well drained by placing a good-sized crock over the hole, and about half a dozen of less size above it; then one-third fill the pot (including the space occupied by the crocks at bottom), with pieces of charcoal the size of a Hazel nut, the small dust being sifted out, which may be mixed with the soil, and turf cut thin and chopped into pieces from half an inch to an inch square. A drainage of this kind seldom clogs, and supplies food to the roots.

The soil I would advise for this and all the subsequent shifts of Roses in pots for the greenhouse, is turf from a pasture closely cropped by sheep, the soil of which is neither too heavy nor too light, but a good hazel loam; whilst for the Tea-scented and China varieties I would give the preference to the turf from a moor or common overlying a sandstone, which when burnt furnishes that which is known as silver sand. I do not mean a peat or bog turf, but one that is neither peat nor loam, and yet both, full of fine particles of white sand. The turf should not be cut of greater thickness than 1½ inch, and if it cannot be exposed grass side downwards to a temperature of 210° in an oven or on a hot iron plate for an hour, so as to destroy all insects, and kill the perennial-rooted weeds, I would use it fresh, chopping it in pieces half an inch square, and making it pretty firm. The old soil in potting should be removed, or at all events the ball gently pressed and loosened. If turf cannot be had, the compost may consist of equal parts of loam and well rotted manure and leaf mould, mixing with the whole a fourth part of pieces of charcoal from about the size of a pea up to that of a hazel nut, which will tend to keep the soil open. After potting give a good watering, and return the plants to the quarters assigned to them the previous year, treating them in the same manner, with the addition of a slight shade for a few days until they have recovered from the potting.

In the end of September, or early in October, the pots should be lifted, for doing so will keep them drier than if they were plunged, and will tend to promote the ripening of the wood, by checking a late growth. By the middle of October the surface soil and that around the sides of the pots should be removed quite down to the roots, but without injuring or destroying them. It should be replaced by the compost recommended for potting, but a year, or not less than six months old, after having been mixed with an equal quantity of one-year-old cowdung. It ought to be laid on level with the rim of the pot, and be made firm. A good watering should then be given, after which the plants may be placed in a cold pit, or cool, dry, well-ventilated house. No more water will be required. In November, or early in December, they may be pruned, which applies more particularly to the Perpetual and Bourbon sections; the Tea-scented and China varieties need not be pruned until introduced into the greenhouse.

To have a late bloom of the Tea-scented, China, Bourbon, and Perpetual Roses, small plants should be potted in six-inch pots in the end of May, or early in June, in the compost already mentioned, and instead of plunging them in the open ground prepare for them a hotbed of dung, 3 or 4 feet in height. This bed being made a week or ten days previous to potting will, by the end of that time, have parted with its rankness and burning heat; spread 2 or 3 inches of sifted tan over the surface, set the pots upon this, and fill up the intervals with tan or sawdust, so as to cover the rims of the pots and the soil which they contain to the depth of about an inch. A bed of tan, 4 or 4½ feet high, is preferable to one of dung, as it retains its heat much longer, and there is no necessity for a second hotbed being made. The plants should be well watered during dry weather, and by the end of July they will have grown amazingly, and the pots will be completely filled with roots. Another bed should be in readiness to receive the plants when the heat of the first, if made of dung, has declined; but whether a dung or a tan bed be employed, the plants are to have nine-inch pots if they have grown well and the varieties are of vigorous habit. Whichever they are, and whether repotted or not, plunge them at once in the new hotbed, or in the old one if it is a tan bed, and in a week shorten the strong shoots to eight leaves or joints, and the moderately strong to six, all flower-buds being pinched off. Water must be given daily in dry weather. I have omitted to mention that the situation should be open, under no circumstances shaded, for their vigour will in a great measure be due to full exposure combined with the bottom heat.

Towards the middle of September, or not later than the end of that month, the pots should be lifted, exposing them for a week half-way, or to one-third of their depth if the bed is still warm, and then withdrawing them fully from the hotbed. In another week remove them to the greenhouse, where the plants will bloom finely in autumn up to Christmas. Water being then withheld, the plants, pruned in February, will produce a fine show of bloom in May in a cool greenhouse. This is the best method that I have tried of growing Roses in pots for a late bloom. The plan is not by any means new; on the contrary, it is a rather old one, seldom, if ever practised, but it deserves to be more generally known. Mr. Rivers first propounded it in the fourth edition of "The Rose Amateur's Guide," published twenty years ago.

The culture of Roses in pots in subsequent years does not vary, for after blooming they may be repotted in pots of the same or of a larger size, and receive a top-dressing of rich compost in autumn. Liquid manure may be given at every alternate watering, from the time of the buds showing until the flowers expand.—G. Abbey.

EVERGREENS NOT GENERALLY KNOWN.

In the large public park belonging to this city (Bath), the endeavour is made to collect all shrubs that are hardy and fitted for the soil, and I have penned some short notices of those I know. The soil is naturally a very heavy blue lias clay, with drifts of oolitic gravel, without a trace of anything resembling peat, so that all plants rejoicing in heath mould or sandy soils cannot be expected to flourish, consequently the list of ornamental shrubs is more restricted than in many other districts.

Aucubas.—At Mr. Standish's first sale I bought a small plant of picta, which was planted out of doors at once, and has become a very pretty bush. It has grown freely, and has been quite untouched by the recent frost. Limbata, sent out by Messrs. Veitch, will be even more beautiful, the margins of the leaves being tinted, not the centre; picta will be handsomer when fully grown, as the central blotch in the young plants does not grow at the same rate as the harder outside green. This centre is often eaten by the snails, whereby young plants are disfigured. A. himalaica is as hardy as possible, and grows more rapidly than the true green Aucuba japonica, or even than the old mottled or the new male.

Of Osmanthus, also bought of Mr. Standish, both the green and variegated kinds are as hardy as need be, and promise to form very pleasing bushes. I have no idea to what family they belong, or to what size they may be expected to grow; looking like Holly, they are of much neater growth.

Euonymus.—The yellow-blotched grows as freely as the original E. japonicus, but quickly loses its yellow colour; whether this will return as the plants grow older is very doubtful, as the old white variegated kind has no marked character, being less effective than the green, and not sufficiently distinct when seen at a distance. All the plants have been pinched by the frost, their tops drooping for some distance. The only way to have the golden Euonymus effective is to be very careful to propagate only the yellow twigs. Euonymus radicans is quite hardy, not being in the least touched by frost. It will probably make a pleasing plant to fill corners, or to grow down walls, as its branches have fibrils resembling those of the Ivy. The branches that have lost their variegation will grow more rapidly than the parent plant. Last year I had from Messrs. Veitch a beautiful variety, Euonymus marginatus, which has grown very pretty, has retained its yellowish white variegation most correctly, and has proved out of doors as little affected as the ordinary sorts. It promises to be a very ornamental shrub.

Elæagnus reflexa is a shrub of very unusual outline, having reflexed branches 6 or 7 feet long, and the whole bush not exceeding 5 feet in height from the ground. The general effect of a large plant is very good, though the colour is dull all the year. In the spring the branches are laden with minute blooms of a very delicate fragrance. The varieties here are the yellow-blotched and marginata. The former, presented to our park by Mr. Godfrey, is as hardy as the parent, which will probably be the case with marginata. The latter, which we had from Mr. Paul, promises to be beautiful, the coloured margin is so clear and bright. Those who wish to plant it permanently must wait for struck not worked plants, otherwise the vigour of the parent will overpower the graft.

Olea ilicifolia is a very handsome compact evergreen, but of very slow growth, and has passed many winters unscathed.

Eurya japonica, a pretty low-growing shrub, is very easily propagated, and of about the same hardiness as the Euonymus, but will not prove of much decorative value, except near the edge of shrubberies. The broad-leaved variegated sort, if moderately hardy, will be more effective. I have had it against a wall for two winters, sheltered by an old window, so that its leaves were just scorched by the frost. These probably would enjoy a peaty border.

Skimmia japonica is perfectly hardy, and blooms and fruits freely, but is of very slow growth.

Quercus glabra will prove a very handsome plant, much resembling in its growth the old Magnolia when grown as a bush, but not so effective.

Photinia has proved hardy here, but the Eugenias require a peaty soil, so they have not succeeded; and Raphiolepis ovata has stood the weather as well as the Euonymus.

The Cabbage Palm of Australia had grown to the height of 3 feet; but all our plants have been killed with, perhaps, one exception. I fear that a large plant of New Zealand Flax, which has stood without any protection the last four or five winters, is also dead. Chamærops Fortuni has been out of doors two years. Each winter it was surrounded by a circle of stakes, over which a mat was stretched, open to the sky; it looked very healthy to-day. The Aralia Sieboldi is sheltered with Laurel branches every winter, but does not at present grow satisfactorily. The Lonicera aureo-reticulata, with its beautiful leaves, especially in the autumn, has proved quite hardy; when growing freely it is much inclined to lose its variegation.—John S. Bartrum, *Bath.*

NEW VARIEGATED BEDDING PLANTS.

I enclose for your inspection a piece of the new Golden Achyranthes, which, except in colour, is a counterpart of the well-known A. Verschaffelti, and will doubtless prove a most valuable plant for decorative and flower-gardening purposes; the contrast between the stem of the plant and the foliage is very striking and attractive. I also enclose a piece of a variegated Euonymus nearly hardy. This is another plant which cannot be too highly spoken of for bedding-purposes, and which is certainly the most beautiful plant of its colour, resembling Graptophyllum pictum in the markings of its foliage. I also send a specimen of Coleus Gibsoni, a plant which I shall use extensively during the present season. All the above will prove acquisitions.—Edwd. Bennett, *Gardener to G. S. Foljambe, Esq., Osberton Hall, Worksop.*

IRESINE HERBSTII IN NORTH AMERICA.

Neither in your Journal nor in other gardening periodicals have I seen any mention of Iresine Herbstii being in flower in England, and I therefore suppose that it has not flowered well with you, if at all. The enclosed flowering tip is from a fine plant in my greenhouse, and if it reach you in as good order as it is at the time of my sending it off it will doubtless prove interesting.

The whole head consists, as you will perceive, of a great many small flowers, each of which, when expanded, is no larger than the head of a common pin; so small indeed are they, that it requires a close examination to distinguish the open flowers from those yet unopened. In colour they are of a delicate straw colour, slightly tinted with green; and the contrast with the glowing foliage is exceedingly good. [The flowers are in spikes, or loose panicles, and have a metallic polished surface.—Eds.]

There was so much talk last spring with regard to the soil and position most suitable to the Iresine, that I put out a number of plants in different places with a view to test this question, and I found the only plants looking well all through the season were those in a northerly exposure, shaded from about ten o'clock in the morning until three o'clock in the afternoon. The very finest plant, now in the greenhouse, and from which the enclosed piece was taken, grew not only in this partially shaded position, but was fully exposed to northerly winds, sweeping over two or three miles of salt meadow, and the Raritan River, about a mile wide at this part. The soil is sandy, well enriched with old stable-manure, made into a compost with leaf mould from the neighbouring woods.

This plant of Iresine stands not less than 3 feet in height by 3½ feet in width; the stalks are thoroughly matured, being quite hard, and, towards the bottom, woody. The general colour of the foliage is a ruddy crimson inclining to maroon, lighted up with carmine and pink, the stems being not nearly so dark as the leaves. Imagine how effective is this beautifully rich foliage, surmounted by plumes of straw-coloured flowers, and with small clusters at nearly every joint.

I must say a word about Teleianthera ficoidea versicolor. Last summer I tried it in dry sandy soil, fully exposed to the sun in the hottest weather we ever had, the thermometer for several days registering more than 100° in the shade. The hotter the weather the more it seemed to thrive, the fine colours coming out with charming distinctness. I am hoping to get the Alternantheras for next summer's trial, and expect great things from them.—George Such, *South Amboy, New Jersey.*

EARLY PEAS.

Before replying to Messrs. Carter & Co. in reference to their note upon my statement, I considered myself bound to discover whether my seed was genuine. My seedsman sold it to me for Carter's First Early, and charged for it as genuine seed. With this house I have dealt for some time, and have always found them honest and upright; I have no right to doubt them now.

In my disappointment regarding Carter's First Early I am not alone; for during last week I met three friends, each a practical gardener, and from them I heard the same statement regarding this Pea as I made in your columns. My object is not to exalt or depreciate any man's pet Pea, but simply to give a fair and honest statement of my experience with new and vaunted seeds.—Ronnoc.

THE NEW KINDS OF VEGETABLES.

As I always read with interest any communication respecting the above I venture to give my own experience for the past few years, for I have tried all new vegetables from time to time as they have been introduced to the public, and have always given them a second chance, not liking to pass judgment for or against them without a fair trial.

I will begin with Peas. For the past three seasons I have tried all the early kinds treated exactly alike in every respect, but in each trial Dickson's First and Best has come off victorious over the following, both as regards earliness and productiveness—namely, Ringleader, First Crop, Dillistone's Early (these three are the same), and Carpenter's Express and Sangster's No. 1, which are identical. Laxton's Prolific I consider one of the very best second early Peas of recent introduction, and one which has not in the least been over-praised. Another, named Albert Edward, which I procured last year from Messrs. Lawson, is of the same class as Champion of England, but much superior to that good old variety, as I had them growing side by side.

As regards Potatoes I have tried all the new kinds that were recommended for garden culture, and find nothing to supersede the old Dwarf-top Ashleaf as a first early, and Handsworth, Daintree's Seedling, and Fortyfold for succession. These are the very best for a garden, as Broccoli, Brussels Sprouts, or any winter vegetable may be planted between every two rows, on account of the short haulm they produce.

I have found nothing remarkable among the Cabbageworts. Dalmeny Sprouts, Albert Sprouts, and Scrymger's Giant Brussels Sprouts are quite useless when compared with a really good strain of the old Brussels Sprouts, which can be had from October till the beginning of April. Of course, this season is an exception, as the frost has made a clean sweep of

everything here, including Cottager's Kale, which is about the hardiest Green we have.

Of Celery I have tried most kinds, but find nothing to equal one of my own, selected from some that stood very late one season without running, and which still maintains its character, as I can have it in good condition some weeks after all other varieties have run to seed. Williams's Matchless I consider the next best Celery in cultivation.

Nuncham Park Onion, I think, will be good, though I cannot speak with certainty till I have grown it another season, but I can say that it is quite distinct from Reading, Trebon, or White Spanish, with which it was said by some to be the same or nearly allied.

In the way of Lettuce, I find nothing so good as Wheeler's Imperial and Victoria for winter, and Neapolitan Cabbage and Paris White Cos for summer.

The Digswell Prize Endive is another valuable addition to our list of salads.—E. Welch, *Palace Gardens, Armagh.*

As the Fearnought Cabbage and hybrid varieties of Brussels Sprouts sent out by us are likely to be more appreciated in future than they have yet been, owing to their extreme hardiness, having stood the late severe frosts without the slightest injury, while many of the other Brassicas have been utterly destroyed, we would venture to throw out a hint which may prove advantageous to such of your readers as may wish to grow them. In many cases new vegetables are grown at great disadvantage, particularly the first year of their introduction, owing to the cultivator not being acquainted with the treatment they require, and are often discarded as being useless and unworthy of a place in the garden without further trial.

The Fearnought Cabbage if not sown early will produce heads as open as Coleworts, but if sown in the first or second week of March, and planted out in due time, it will have nice firm heads before the winter sets in, and will keep longer without bursting than any other of the Brassica tribe, remaining perfectly sound till the early summer Cabbage comes in. Although when growing its appearance is coarse, the flavour is much superior to that of the early dwarf Cabbages.

The Dalmeny Sprouts should also be sown as early as possible, or as soon as the ground will admit; if delayed too long they will not form the Cabbage heads on the top. The same treatment is also requisite for the successful cultivation of the Albert Sprouts and New Dwarf Sprouting Ulm Savoy.—Stuart and Mein, *Kelso, N.B.*

WHAT IS A GOOD CROP OF STRAWBERRIES?

This is the inquiry of your correspondent "S. E. T.," who then goes on to say that had I stated the distance between the rows and the plants my article would have been much more valuable. Now, if your correspondent will again read the article in question (Vol. X., p. 213), he will find there the required particulars. For the information, however, of those who may wish to know what room was occupied by the plants from which I gathered the 96 lbs. of fruit, I may state that they were planted on a piece of ground 17 yards long by 14 feet 6 inches wide, allowing a space of 1 foot 4½ inches outside all the plants, which could not be occupied by any other crop. This is the regular distance at which I plant all my main crops of Strawberries, and I find them succeed better in this way than in any other which I have tried, and I have tried several.

About eight years ago I was living in the neighbourhood of the great Strawberry district—Twickenham, Isleworth, and Brentford, in Middlesex. There I saw many modes of culture and many good crops, some of which, I think, had they been fairly weighed, would have averaged nearly as great a weight as that described.

"S. E. T." quotes my crop as a standard to test others by. This was far from my idea when I wrote, as I think that many of the Strawberry-beds in the country could be made to bear even a larger crop than that described if better modes of culture were adopted.

I should have stated that the land on which this crop grew was three years previously enclosed from an open field, and was afterwards very heavily manured every year for other crops up to the time of the Strawberries being planted. This, I have no doubt, greatly conduced to the production of a heavy crop.

"S. E. T." remarks that a degree of looseness of statement with respect to weights, &c., is prevalent, thereby making it appear that he is doubtful if my figures are correct. Let me assure "S. E. T." that the weights and scales by which the produce was weighed were corrected by the standard; and that I weighed all the fruit myself, in the presence of two other persons, in 14-lb. lots, giving quite half a pound over each time. This I was very careful about; and I should be extremely sorry to send anything to you for publication, no matter how trifling, without first correcting any statement I may have made from notes taken at the time.—John May, *Westfield.*

METEOROLOGICAL NOTES IN 1866 AT LINTON PARK, KENT.

The past year, unlike its successor, was deficient in the one extreme of temperature, which was heard of or felt by every one in the south of England. It was also in no way remarkable for attaining the other extreme; in fact, 1866 may be summed up as having had a mild winter, a rather late spring, a moist but not ungenial summer, and a very mild autumn. Considerably more than the average amount of rain fell; and following as it did the copious downfall of 1865, I find the total amount in the two years is 4½ inches more than in 1855, 1857, and 1858 collectively. The rainfall, however, in 1865 and 1866 having been better distributed than in 1860, these years have escaped being called wet, which the latter will be remembered as, although at this place more rain fell in 1865 than in 1860.

The following notes on 1866 will show some of its leading meteorological features:—

	Rainfall in inches.	No. of Rainy Days.	No. of Frosty Days.
January	3.83	21	7
February	4.55	20	13
March	2.27	17	13
April	2.09	16	2
May	0.81	8	5
June	3.40	9	..
July	2.70	10	..
August	2.15	16	..
September	4.25	23	..
October	1.38	11	4
November	1.89	13	12
December	1.47	15	10
Total 1866	30.79	179	66
„ 1865	35.18	172	80
„ 1864	21.25	156	96
„ 1863	22.75	169	64
„ 1862	26.93	195	67
„ 1861	24.01	168	85
„ 1860	33.66	216	93
„ 1859	29.55	151	93
„ 1858	16.33	116	93
„ 1857	24.33	137	..
„ 1856	27.79	169	89
„ 1855	20.84	160	114

From the above it will be perceived that the frosts here were fewer last year than in any preceding one in the table, with the exception of 1863. This, and probably the great amount of rainfall, are due to the prevalence of south, south-west, and west winds; for in noting the wind at noon each day, and regarding only the eight cardinal points, I find the wind from the above quarters on 214 days in 1866, but only on 122 days in 1855, whilst it blew from the north-east on 115 days against 31 last year. The wind is from the east on a less number of days than from any other direction; even in an unfavourable year thirty-four is the highest number I have recorded, last year the number of days was sixteen.

As an instance of the mildness of the autumn, I may state that on December 30th two conical pillars of Pelargoniums, 7 feet high or more, in quite an open space where there was no shelter so high as themselves within 100 feet, were almost as fresh as in October. Some rather sharp frosts in November had injured the plants, but they recovered, and were quite in a growing condition. Their elevation above the surface prevented damp injuring them so much as it did those elsewhere; and I need hardly say that Verbenas and similar plants were also uninjured.

By way of an appendix to the foregoing notes of 1866, it would be as well to report upon the changes which its successor has brought. The frost, commencing with the last day of 1866, has proved to be one of those special cases of severity which only after a cycle of years we are wont to look for, and as each visitation differs from its predecessor, so has that of 1867 had its peculiarities.

I do not rely on the readings of the thermometer alone as a proof of the cold, or rather of the difference of heat, but on the effects as regards vegetation, which here at least have been so singular as almost to deserve the term capricious; for while at one place Laurustinus and even common Laurels were all but killed, at others in about the same altitude no harm has been done, and yet the conditions in both cases were apparently alike. I may, however, add, that prior to the frost commencing on December 31st, we had had a long period of dull mild weather, with so very little frost that the two conical pillars of Pelargoniums before referred to were quite fresh and looked as well as two months before that date, the injury resulting from some sharp frosts in November having been repaired by the after-growth. Now, it is easy to conceive what effects might follow an intense frost suddenly falling on plants which had scarcely encountered autumn cold; but fortunately for low-growing plants, the first frost was speedily followed by snow, so that when the cold was most intense, a covering of 8 or 10 inches of snow effectually saved many from destruction. As an instance of this, I may mention that we obtained a considerable number of Verbena cuttings, from a bed fully exposed, on the 10th of January, after the first winter had passed away. Plants above the snow-line, however, fared much worse, and it is difficult to state how much damage has been done.

Before, however, I enter into this subject, I may mention that a minimum registering thermometer placed in a perfectly open place about 3 feet from the ground, and at an altitude of about 300 feet above the sea level, did not fall lower than 10°, or 22° of frost, and I have no reason to doubt its accuracy, as no particular injury was done to anything there beyond that which occurs in ordinary sharp frosts; while at less than 200 yards distance from the same spot, and about 40 feet lower down, several shrubs and trees have suffered severely, although in a place sheltered in all directions but the south and south-west. Only a very short distance from the latter spot, and in a situation much the same in every respect, the same sorts of trees and shrubs escaped altogether or nearly so. Now, why was this? Is it possible for a wave or volume of cold air to settle itself in one particular place, and not mix with other portions of the atmosphere less cold than itself? Certainly the stillness of the night would favour this idea, yet it is laid down by those acquainted with the laws of nature, that such an occurrence is not likely to take place in so circumscribed a space. The damage, however, in one particular place was so much greater than elsewhere, that there would appear to have been a difference in temperature similar to that which exists in hot days between the south and north sides of a wall, and which amounts to several degrees; at least, this is the only explanation which I can offer, but, perhaps, some of your readers may give a better reason. I may further add, that the place where the frost seems to have been most severe, was about 250 feet above the sea level, whilst at about 350 or 380 feet the decrease was scarcely perceptible, and it is remarkable that some common Laurels, Laurustinus, and other shrubs growing near a piece of water on cold clayey soil at not more than 150 feet of elevation, suffered less than those 100 feet higher up. Such results are perplexing.

With regard to the effects of the frost, and commencing with common shrubs, I may state that those which have suffered are most injured on the south-west side. Laurestines are in some places all but killed, Portugal Laurels not in the least hurt, common Laurels in places browned severely on the tops, and Garrya elliptica more injured against a south wall than in the open ground. Berberis Darwinii, Wallichii, and aquifolium escaped entirely, while B. japonica and Fortuni look ill. Griselinia littoralis has been much injured where not covered with snow, and still more so is Phygelius capensis; in fact, it is killed to the ground I believe, and the same is the case with some Fuchsias which have withstood four or five winters, and have stems 3 inches in diameter or more. Phillyreas have all escaped, except one singular kind, with long willow-shaped leaves. Colletia horrida is injured, but not so much so as C. bictonensis; the latter, I think, is killed. Sheltered by a wall, Desfontania spinosa seems unhurt, and the new Japanese evergreen Raphiolepis ovata shines as brightly as before the frost. I may add that this pretty little evergreen shrub bears berries most profusely, some plants not a foot high having nice clusters upon them; it seems, however, to be of slow growth, like Skimmia japonica. The latter seems on the whole to be improved by the cold, but it was well covered up with snow, and so were all the Pernettyas that I had planted.

Some plants of the old White Indian Azalea growing near a tree of Pinus insignis, much hurt, were not in the least injured, but the purple variety in some places was very much injured. Camellias planted out, though they have not escaped scathless, were less injured than most things, and Magnolias of some size against a wall were browned a little. Myrtles in some places were all but killed, and I believe Ceanothus papillosus to be quite destroyed; C. dentatus is injured, and I expect to lose some plants, but fear a greater loss in C. azureus. New Zealand Veronicas, both variegated and plain-leaved, are killed to the ground, as likewise is Clianthus puniceus, which has stood several winters with the protection of a mat against it in very cold weather. Euonymus japonicus of the old kind is destroyed where not protected by snow, but the newer Japan kinds, E. radicans and aureo-variegata, are as fresh as ever under the snow. Eugenia apiculata against a wall is injured, but not fatally; and Escallonia macrantha has lost its beauty, but not its life. A hardy Passion-Flower, whose blossoms still lingered with us up to the middle of December, has a very withered look now, but I think the main stems are alive, while a very humble plant with me, Illicium floridanum, is unscathed. Sweet Bays in some places have suffered much, in others scarcely at all. Benthamia fragifera is, I fear, all killed above the snow line. Osmanthus ilicifolius, a pretty Holly-looking plant from Japan, seems as hardy as our native favourite, and its half-namesake Olea ilicifolia suffered as little, but O. europæa was unhurt. Photinia serrulata, whose bursting buds and apparent continuous growth render it particularly susceptible to cold, has not suffered much, but a Nerium Oleander which stood last winter against a wall is, I expect, quite killed now. Arbutuses are scarcely in the least touched, and stand proudly amongst some other things much injured, and I believe all the Hollies are untouched.

Deciduous plants have mostly escaped. Weigela rosea seems fresh, and so does the Deutzia; but my experience in Roses is less important, as we mostly grow dwarf ones and on their own roots, and the snow helping to keep them from harm, the damage is confined to the China and other less hardy sorts. I also find that an edging plant which is not so much used as it deserves to be—namely, Santolina incana, is perfectly hardy. The Chinese Palm, Chamærops Fortuni, is still more so; its glossy green leaves appear to be improved rather than otherwise by the cold. The Pampas Grass has, I fear, suffered to an extent that will prove fatal to half the plants we have; and I am afraid the same may be said of Tritoma uvaria. It is a singular fact as exemplifying the mildness of the autumn, that when the frost set in, in four beds of this plant there were numerous spikes of flowers in excellent condition, and others of different heights rising up from the bottom. The large plants, however, I fear are entirely killed; but a day or two ago I noticed a small one, only a few inches high, in a fully exposed place, with two blooms on it, which were quite fresh and unhurt by the weather, the snow having protected them. I may also remark, in connection with the above fact, that Calceolaria cuttings in a cold pit, with no other covering than a glass light and snow, have not sustained much injury, C. amplexicaulis with one or two other tender varieties being the only sufferers. I must not omit to mention that a fine plant of Ligustrum japonicum, nearly 20 feet in height and more than that in diameter, which has annually furnished hundreds of spikes of bloom, is very severely injured, having been deprived of most of its leaves. The common Ligustrum, L. ovalifolium, has also had its beauty everywhere destroyed.

Of the larger plants, I am sorry to state that my opinion of the perfect hardiness of one or two of the most popular of the Pinus tribe is much shaken, as a fine P. insignis, upwards of 50 feet high and nearly as much in diameter, is slightly injured, and another, somewhat less, has suffered very much. P. excelsa growing in the same situation bears no marks whatever of the cold weather. Pinus Benthamiana and P. ponderosa seem equally hardy, and none of the Picea tribe appear affected, P. pinsapo, cephalonica, nobilis, and Nordmanniana being all as good in appearance as before. The same cannot be said of Abies morinda, as a plant or two growing in an exposed situation are injured on the south-west side, while several others in the grounds have not suffered in the least. I may also add that near to the Abies morinda referred to as being injured there are both Deodars and Cedars of Lebanon in like manner sufferers, the spot they occupy being that where the frost appears to have been most severe; both species are much injured; the trees are 20 or 30 feet high. It is gratifying to find that the more recently introduced Thujas and Thujopses show no signs of injury, although growing in the same situa-

tion, for Thuja Lobbii, gigantea, and Menziesii appear in the same garb as before; and the same may be said of Thujopsis borealis. I hardly know whether to include T. dolabrata in the same list or not, as the plants are small, and were much covered with snow. The new Retinosporas seem to be hardy enough, R. pisifera, which is 8 feet high, being quite uninjured; and the same is the case with R. obtusa, leptoclada, squarrosa, and, I think, ericoides, but I am not certain as to the last. The members of the genus Cupressus also seem to be generally hardy. C. Lawsoniana was not hurt; perhaps there was a shade of difference in the tint of C. macrocarpa as compared with that which it previously exhibited, but it is only a shade; and Taxodium sempervirens growing both in dry and damp situations seems capable of withstanding any amount of cold which is likely to occur in our climate, for I see no difference in its appearance now from that which it offers after mild winters; and the same is the case with Cryptomeria japonica and C. Lobbii. I have, however, to lament a sad accident that befel a specimen of Cryptomeria japonica: a high wind on the 8th of January broke off upwards of 14 feet from the top of our highest tree, which, before the accident, was about 40 feet high, as straight as an arrow, and tapering from only about 10 feet in diameter at bottom to the top. I am glad to say that I expect Cryptomeria elegans will prove hardy, as the shoots, though brown, are not killed, and the rich brown tint which it assumes in autumn before any cold sets in is, perhaps, an advantage rather than otherwise. Some other species of Abies, such as A. polita and microsperma, were too small to report upon. I may, however, remark that Picea lasiocarpa seems hardy.

As we are too apt to magnify present evils as exceeding former ones, it may, perhaps, be premature yet to compare this winter with others of a severe character in years gone by, until the full extent of the injury be known; but at this place the frost has certainly been more destructive than that of 1860–61. The cold in February, 1854, certainly exceeded that of the present year, and as far as I can remember its results were as disastrous, though not to Conifers. I may add that Wellingtonias in all situations have escaped unhurt, whilst other plants hitherto regarded as perfectly hardy have suffered; the mischief here has been chiefly confined to a particular part of the ground that had escaped in former years, and in such a manner as leads to the impression that an intensity of cold prevailed in a certain plot of a few acres in extent which did not exist in another situation of equal altitude but a short way off. This, however, is a subject I can only give an opinion of, but on a more extensive scale there is proof enough that it has been so, as witness the disparity of thermometric readings.

It remains only for me to remark that in the kitchen garden, which here is on a higher level than the dressed grounds, the loss is not so serious as on some occasions; but all tall Broccolis are either killed or much hurt, while dwarf varieties, being under the snow, escaped with more or less damage according to the protection which they had, the advantages of a snow covering being most apparent in a breadth of Spinach, which looks as well now as at Christmas. Of Lettuces and similar low crops the same remark holds good.—J. Robson.

FRIENDS IN CANADA.

"Great welcome makes a merry feast."

The perusal of "Wiltshire Rector's" prose Christmas Carol in the Christmas number of the "Journal" was a source of much pleasure to one English family living in exile in far-distant Canada.

We also, like your worthy contributor, are fond of Christmas carols, and more than one comfortless night have we spent in the keen frosty air in order to indulge in singing, under the window of our rector, the good old carol of "Helmore," as we devoutly shun any of the "Annie Laurie" type. Oh, that the Wiltshire robin had warbled for us! We would have wished him no "bone in his throat;" he would have been doubly welcome; for through the long dreary Canadian winter we have no songsters to enliven us, or disturb the dismal stillness—not even a crow. We, too, should consider ourselves happy to wish our friends a "Happy New Year" in an English temperature.

Fancy, you people in good old England, turning out on New Year's-day with the thermometer at 20° below zero, and a gale of wind blowing! The good old angel Christmas had need come with plenty of good cheer in such an inhospitable climate as we live in; but, although our winters are long and severe, our summers are warm, and all the hardy fruits are grown with much success. Peaches were formerly a certain crop; but of late years, owing to the extreme cold, the result has been very uncertain. Apples, Pears, Plums, Cherries, and the small fruits, with the exception of Gooseberries, all do remarkably well, but as a general rule are very deficient in flavour when compared with English fruit. The native Grapes are also widely cultivated, but the disagreeable aroma which distinguishes them makes them very unpalatable to an Englishman.

As "Wiltshire Rector" remarks, we readers of the "Journal" (our Journal I should have said), seem like brothers, as indeed we are. Nothing is looked forward to with more pleasure in this household than the arrival of our favourite. "Dear me! how late the Journal is this week!" is often heard; and when it does arrive, it is not long before its pages are well read. It seems like one of the connecting links that bind us to "our island home," and nothing in its pages imbues us with a more fraternal feeling than the contributions of "Wiltshire Rector." Long may he be spared to enliven with his genial style the columns of "our Journal;" indeed, we should be sorry to miss the well-known names of any of its regular writers; and until we again set foot on our native land, for I trust our exile draws near to a close, welcome, thrice welcome, to our fireside here will be our weekly friend. I trust that this response from beyond the seas to "Wiltshire Rector's" desire to know more of our fraternity, will prove to him and all connected with the Journal, that their efforts to do good and make life pleasanter have not been in vain.—W. T. Goldsmith, *St. Catharine's, Canada West.*

[The Editors kindly sent to me the manuscript of the above; and I speak truly when I say that no letter that the postman ever brought to me gave me greater pleasure. It reached me on a Sunday morning, while the church bells around were proclaiming the day of rest and blessing to man, and it warmed and cheered my heart; and when, a few hours after, I was leading the sacred service in my own Ivy-clad village church, my thoughts strayed to the kind writer and his family in far-distant Canada, who, perhaps, at the same time were joining in the same holy words. I thank our Canadian friend for his fraternal greeting. I thank him on behalf of "all the regular writers" in this periodical, for he includes all; first and foremost on behalf of the Editors, then on behalf of the rest whose words he frequently reads, and lastly on my own behalf. It is pleasant to know that the bread we have cast upon the waters has not only done a good work, but that we are thanked for it. It is pleasant to put thoughts on paper which have given us pleasure, and then to know that they have given pleasure to others. Our walk in literature is not a lofty one, but not the less useful; we inform the mind, we give hints of use to those who earn their daily bread, and better still, we at times, so it seems, reach the heart. We think we add to home comforts, and make the home circle draw closer, by drawing it around our Journal as a centre. I was aware this periodical was warmly welcomed in many an English home; but it was a new pleasure to find that we brought old England to the mind's eyes and hearts of our colonists, deadening for a while "that wasting pang—home-sickness." We in England join in wishing Mr. Goldsmith and his family well, and, in thought, stretch a warmly grasping hand to them in far-distant Canada. And may they continue to derive pleasure from our pages; and when reading of our English gardens and homes may they feel for a while (so fancy oft cheats man pleasingly), that they are looking at our bright flowers, and listening to our merry English birds. Wishing well, therefore, to all under Mr. Goldsmith's roof tree, and that they may soon walk in English fields and gardens, and be exiles no longer, I remain theirs fraternally—Wiltshire Rector.]

TRANSPLANTING LARGE FRUIT TREES.

On opening your Journal of February 14th I was not a little surprised to see a communication from "T. P. I." on the very trees I mentioned in my paper sent last week. As a commentary on his observations, I beg to state that only a few of the Peach trees had been planted previously to my taking charge of the garden at Oakley Hall. The Pears had been planted two years. The large Apricot mentioned must have been fully thirty years old, and one Pear much older.—Wm. Robins, *Oakley Park, Suffolk.*

West of England Rose Show.—This Show, to be held at Hereford, is postponed to July 9th, on account of the Show at South Kensington being on the day previously announced.

PORTRAITS OF PLANTS, FLOWERS, AND FRUITS.

Tapeinotes Carolinæ (Empress Charlotte's Tapeinotes).—*Nat. ord.*, Gesneraceæ. *Linn.*, Didynamia Angiospermia. Native of Brazil, and named after the Empress of Mexico. Introduced by Mr. Bull, Chelsea. Steve shrub. Flowers white. Leaves crimson beneath.—(*Bot. Mag.*, 5623.)

Angræcum citratum (Citron-yellow Angræcum).—*Nat. ord.* Orchidaceæ. *Linn.*, Gynandria Menandria. Native of Madagascar. Introduced by Messrs. Veitch. Flowers very pale citron colour.—(*Ibid.*, *t.* 5624.)

Impatiens latifolia (Broad-leaved Cingalese Balsam).—*Nat. ord.*, Balsamineæ. *Linn.*, Pentandria Monogynia. Native of Ceylon jungles. Flowers pale purple.—(*Ibid.*, *t.* 5625.)

Clavija fulgens (Brilliant-flowered Clavija).—*Nat. ord.*, Myrsineæ. *Linn.*, Pentandria Monogynia. Native probably of Lima. Flowers scarlet with yellow centres.—(*Ibid.*, *t.* 5626.)

Mesospinidium sanguineum (Rosy Mesospinidium).—*Nat. ord.*, Orchidaceæ. *Linn.*, Gynandria Menandria. Native of Peruvian and Quitensian Andes. Flowers pale rose-coloured.—(*Ibid.*, *t.* 5627.)

Barleria Gibsoni (Dr. Gibson's Barleria).—*Nat. ord.*, Acanthaceæ. *Linn.*, Diandria Monogynia. Native of Central India. Flowers dull pale purple.—(*Ibid.*, *t.* 5628.)

Lilium hæmatochroum (Blood-red Lily).—Very dark crimson, with stripes still darker. Flowers very large. Introduced from Japan by M. Verschaffelt.—(*L'Illustration Horticole*, *p.* 503.)

Gladioluses.—*Impératrice Eugénie.*—Large and beautiful; white streaked with rose, and the side segments entirely rose. *Reine Victoria.*—White streaked with crimson. *John Waterer.*—Scarlet streaked with white. Raised by M. Souchet, head gardener at the palace of Fontainbleau.—(*Ibid.*, *p.* 504.)

Rhododendron maroinate-punctatum.—Raised by M. Verschaffelt. Ivory white spotted with crimson.—(*Ibid.*, *p.* 505.)

Myosotis alpestris.—"Myosotis rupicola—or *alpestris*, for the two names are synonymous—is a dwarf perennial, found in a few elevated northern localities in England and Scotland, but always exceedingly rare. We are indebted to Messrs. Backhouse & Son. of York, who exhibited plants at South Kensington in 1865, for the opportunity of figuring so charming a group of it. Mr. J. Backhouse, jun., writing from Teesdale on the 15th of May in that year, observes, 'The wild Teesdale locality of our M. rupicola was buried in snow apparently a feet thick, extending 500 feet down the sides of the mountain (Micklefell), and extending for ten miles along the summit ridges, only two days ago!' and he adds that the M. alpicola of their catalogue of 1864 is a synonym, as also is the M. alpestris of Hooker and Babington; but he goes on to say, 'It is certainly not the continental alpestris, which I believe is only a mountain form of sylvatica.' The dwarf habit and large richly-coloured flowers of this plant render it most ornamental either for moist rockwork with a north aspect, or for the alpine frame, and in such situations it succeeds very well, the principal feature in its treatment being to prevent its becoming too rapidly excited by excess of heat. What it requires is a cold, moist situation, where it may remain at rest all the winter."—(*Florist and Pomologist*, vi., 21.)

ENTOMOLOGICAL SOCIETY.

The first meeting of this Society during the present month was held on the 4th inst., the chair being occupied by Professor Westwood. The minutes of the anniversary meeting held on the fourth Monday in the preceding month were confirmed, at which meeting Sir John Lubbock had been re-elected as President, and Mr. Dunning as Secretary, Dr. Sharp having also been elected as joint Secretary in the place of Mr. Edwin Shepherd resigned. The annual prize of five guineas offered by the Council for the best memoir on some beneficial or injurious species of insect, had been for the second time awarded to Dr. Wallace, of Colchester, for his memoir on the Oak-feeding Silkworm of Japan (Saturnia Yama-mai), and the President delivered his annual address, which was ordered to be published and distributed among the members at the present meeting. The President, by letter, nominated Professor Westwood, Mr. F. Smith, and Mr. Stainton, as Vice-Presidents for the ensuing year.

The Secretary announced that the Council had again renewed the offer of two prizes of five guineas each, for the best memoirs on the anatomy, economy, or habits of any insect or group of insects especially serviceable or obnoxious to mankind. The memoirs to be sent to the Secretary, indorsed with mottoes, on or before the 30th of November next, when they will be referred to a committee to decide upon their merits.

Mr. F. Bond exhibited four specimens of a Lasiocampa, reared by Mr. Mitford, from golden-coloured caterpillars taken on the Kentish coast, and which fed upon Clover and Grass. The perfect Moths differed so much from L. Trifolii, as to lead to the belief that they belonged to a distinct species. Also, a singular variety of Dianthœcia capsicola from York, and four curious monstrosities occurring in the genus Argynnis, the wings of these Fritillary Butterflies being unequally developed. He observed with reference to the habit of the Humming-bird Hawk Moth, of flying about sunny walls and cliffs, that the object was to find out some convenient crevice in which it could take its midday siesta, the insect having two periods of flight in a day. This statement was confirmed by Dr. Wallace, who had found the insect apparently asleep and inert at noon in a hollow shell, which it had selected for its retreat.

The Chairman exhibited a very small and curious variety of Mamestra Brassicæ, captured by Mr. Briggs, of St. John's College, Oxford; and Mr. Ianson, a collection of Coleoptera, collected in Vancouver's Island. Amongst the species were some interesting Beetles, especially a Longicorn, closely allied to the curious Australian genus Hesthesis.

Mr. G. S. Saunders exhibited the nest of a social caterpillar, formed among the leaves of a species of Zeyhera, from the province of Sun Paulo, Brazil. The nest was of a strong texture, and nearly a foot long.

Dr. Wallace mentioned that he had recently observed in Mr. Bree's collection, a specimen of Platypteryx sicula, believed to have been captured by the latter gentleman near Stowmarket. He also exhibited a cocoon of Saturnia Yama-mai, bred in England, together with a very remarkable series of cocoons and perfect insects of the Ailanthus Silk Moth, reared by himself, as well as specimens of the silk obtained by carding from the latter species, accompanied by a series of observations made during his experiments on that insect in 1866. Among the specimens exhibited were cocoons which had been spun up at the end of 1865, but from which the Moth had not yet emerged, having remained nearly a year and a half in the chrysalis state; also, double cocoons spun by two caterpillars conjointly. He had reared more than four thousand of the Moths during the past year, and had observed that the cocoons kept in the darkest places produced the brightest-coloured Moths. He was inclined to believe that S. Guerinii, and S. Ricini, were only local varieties of S. Cynthia. He also mentioned that the eggs of this Moth make a distinct, although slight, clicking sound often repeated.

Mr. Wormold exhibited a collection of insects sent from Shunghai by Mr. W. Pryer, most of which were almost identical with British species. It included, however, a new wild Silk Moth nearly akin to Bombyx Huttoni, Westw.

Mr. J. Gould exhibited Hylurgus piniperda, a small wood-boring Beetle, which was committing great ravages on Pinus insignis in Lord Falmouth's park, in Cornwall.

Mr. C. A. Wilson, of Adelaide, communicated a further series of notes on the Buprestidæ of South Australia, and on Cerapterus MacLeaii, and Calosoma Curtisii.

THE INTENSE COLD AND ITS CONSEQUENCES IN SHROPSHIRE AND CORNWALL.

Church Aston, Salop.—I send you the result of my observations on the degree of cold and its effect in this neighbourhood (Newport, Salop). Its greatest intensity was in the night of Thursday, January 4th, when my self-registering thermometer in the shade, against a wall 5 feet from the ground, indicated 6°, or 26° of frost; but I am inclined to think that the position of the instrument in the north-west angle, formed by a wall and building adjoining, caused it to register higher than it should have done. At Chetwynd Park, within two miles, I am told that the thermometer was at zero.

The frost commenced here with snow on the last day of the old year; it continued until the 6th of January without severity, except on the 3rd and 4th. The thaw continued from Sunday, 6th, to Thursday, 10th, the temperature during this interval rising as high as from 45° to 50°. Frost commenced again on the above date, and continued thirteen days—that is, to Wednesday, the 23rd. During this interval we had no cold so intense as in the first frost, the lowest degree of cold registered here being 15° in the night of the 14th; but during most of this time the thermometer ranged between 20° by night and 29° by day. I need scarcely say that the frost was accompanied with a considerable fall of snow in this, as, I suppose, in every other county. We had snow on December 31st and January 1st equivalent to about a quarter of an inch of rain, as registered by my rain-gauge. On the 10th, 11th, and 12th we had snow equivalent to about one-fifth of an inch of rainfall, and on the night of the 22nd that storm of sleet or snow and rain together, which seems to have been so general throughout the country.

As regards the effects of this frost, as far as we can judge at present they do not seem so disastrous as might have been

anticipated. Although I quite agree with your valuable correspondent Mr. Radclyffe, that it will not be until the spring that we can tell to what extent our Roses and other hardy trees and shrubs may have suffered; yet, as far as my observation has gone, the losses amongst Roses will not be considerable. I have noticed, and I should be glad to know if others of your correspondents have observed the same, that the old two-year-old wood of my Roses seems to have suffered to a greater extent than the newer, greener, less-ripened shoots. I cannot say that any of my Roses are killed, unless it be two or three plants of Triomphe de Rennes, but I fully expect many of those on the Manetti stock to die down to the snow line. Some of them present the singular appearance of having been crushed for an inch or two about this line, not by the bark or stem appearing to be bruised or wounded, but by its discoloration, while the upper part of the branch above this line appears at present quite fresh and uninjured. The only protection I afforded to the bulk of my Roses was to increase the thickness of Nature's best blanket by having more snow shovelled on to my dwarfs, whether on their own roots or on Manetti; and in the case of my newly-budded Manettis the application has been thoroughly successful, as even in the case of some Teas the buds look as green and fresh as the day they were put in.

One beneficial result, amongst others, of the severe frost will be to prove thoroughly the hardiness or otherwise of the new Roses of the last three or four years, and how far Roses on the Manetti are better able to resist the effect of such intense cold than those on their own roots or on the Briar, and it will be a great boon to amateur rosarians if, as the season advances, some of your readers will give lists of what Roses have been killed or suffered most from the effects of the late frost.

None of my hardy shrubs as yet show any sign of injury, though Broccoli and Celery seem to have suffered considerably.

I must not forget to mention, in passing, that so late as January 19th I had a good covering of straw put round some pillar Roses which I was anxious, if possible, to preserve from injury. These are trained to circular iron trainers, and straw was placed round them, to the extent of an inch in thickness, from the ground to a height of 4 or 5 feet, leaving still 2 or 3 feet of the top of the shoots exposed. If this had been put on previous to the severe frost it would no doubt have proved a protection against almost any degree of cold; but as it is, I hope it may still be of use, as I am convinced that plants suffer as much from sudden exposure to bright sun or drying winds after such weather as we have had, as from the effects of the intense cold.

I am surprised to find how little plants have suffered in cold frames in comparison with what I should have expected, for though protected with additional covering, and in the case of the first frost to some extent with straw, the intensity of the cold was such that I expected much more damage to have been done than has been. How is this? Did the late mild autumn cause the loss of ground temperature to be much less than is usual on the approach of winter? and when we came to cover up our cold frames closely, was there, therefore, much more of it than common at this time of year stored up to resist such frost as we have had lately? Unfortunately I had no self-registering thermometer in any of my cold frames, so that I have no means of telling with exactness what was the temperature; but I find the injury to my Calceolarias, Gazanias, Carnations, Tea Roses, and other occupants of my cold frames almost nothing. Verbenas, Humeas, &c., in the same frames have suffered more; but I might, without difficulty, have added such additional protection as would have saved these too.

No doubt the small injury done to vegetation compared with the severity of the past frost is to be attributed entirely to the beneficial protection of the snowfall, which was more or less abundant throughout the country.—Country Curate.

Penzance.—Frost commenced on December 31st, 1866, and continued till January 4th, 1867. The lowest temperature during these days, by Negretti & Zambra's self-registering thermometer, was 27°. In a garden near this place none of the plants enumerated below, excepting Sparmannia africana, then in flower, suffered. On January 11th frost set in again. On the 14th the snow was 5 inches in depth. On the 15th and 16th the minimum during the preceding nights was 15°, an excess of 7° of cold beyond what I have ever observed during the twenty-eight years of my residence in Cornwall.

I find this day (February 6th), that the following plants in the borders and unprotected have been killed:—Hakea acicularis, Sparmannia africana, Eutaxia myrtiflora, Serissa marginata, Acacia armata, Eriostemon pulchellum, Pelargoniums, including some of the Cape kinds which had survived many winters here and in the Scilly Islands; and Alona cœlestis.

Severely injured:—Veronicas (various shrubby kinds), Aster argophyllus, Polygala Dalmaisiana, Gazania splendens, Boronia tetrandra, Myrsine undulata, Centaurea ragusina and gymnocarpa, and Cineraria maritima. Cassia corymbosa has lost the wood of 1866.

Slightly injured—*i. e.*, extremities of shoots pinched:—Myrtles, Erica codonodes, Colletia spinosa, Witsenia corymbosa, Mitraria coccinea, Correa alba, and Hakea suaveolens. Several plants of Ghent Azaleas were unhurt, a young leaf or so at the extremities of the shoots only being destroyed. The same with Camellias, among which there was no damage except where the new growth had already begun.

Unhurt:—Gunnera scabra, Dracæna indivisa, Yuccas, Rhododendron arboreum, Abutilon vitifolium, Erica arborea, Colletia bictonensis, Olea ilicifolia, and Convolvulus cneorum.

No Roses whatever have been damaged; but Fuchsia fulgens, splendens, and serratifolia are killed to the ground.

So many of the plants above mentioned are usually only found under glass during winter, that the effect of the late frost upon them may be useful. The result that most surprises me concerns the Dracænas, of which I have three specimens, one 9 feet and the others 6 feet in height. That they should have survived a temperature so low as 15° was beyond my expectations, especially as, when frost set in after the snow on their leaves had been melted by the sun, the hearts of the plants were covered with a solid block of ice. I speak of these plants as D. indivisa, but some think that they are D. australis.

The Orange trees, Pelargoniums, and Calceolarias in a badly glazed lean-to greenhouse, without any heat but that of a paraffin lamp during the night, had only a leaf here and there touched, although on one night the minimum was 22°, and on three others 23°. In wooden frames matted over, and filled with Zonal and Variegated Pelargoniums, Heliotropes, and other bedding plants, nothing was injured beyond the tips of the Celsias and of the Ivy-leaved Pelargoniums in one corner.

Our district is one in which market-gardening is carried on to a large extent. At this season the main crop is Broccoli, of which acres are destroyed. The Potatoes, fortunately, were still in safety on their shelves, as the practice of November planting has been almost wholly given up in this neighbourhood.—W.

NOTES AND GLEANINGS.

One of the novelties for which we anticipate a large measure of success is a new Black Grape, raised by Mr. Standish, which we noticed in our pages two years ago under the name of Royal Black, but which he has since changed to Royal Ascot, as indicating more distinctly its origin. For some years Mr. Standish devoted his attention to the crossing of Grapes, and one of the crosses he attempted was to get a result partaking of the character of the Muscat of Alexandria and the Trovéren Frontignan; and for this purpose he used the Bowood, which at the time was considered an earlier form and generally a superior variety of the Muscat. To his astonishment, instead of a white Grape he obtained a black one, and instead of a Muscat a variety with a large oval berry, of a character very similar to the Black Hamburgh, and with a sensible though very faint trace of Frontignan flavour. Our object, however, in noticing this subject at present is to report what promises to be its great fertility and wonderful vigour. Mr. Standish has planted a whole house with it for market purposes, and the Vines, though only planted twelve months ago, show on each lateral as many as four large bunches, and on some of the rods we counted as many as forty in all. The fruit is earlier than the Black Hamburgh by a week, and it has the peculiarity of being of a jet black colour long before it is ripe, being in that respect like the Red Chasselas, which colours as soon as the berry is formed. Judging by what we saw of the fruit last year, the remarkably stout stalk, and the short, sturdy, warted berry-stalks, we believe that this will be equally valuable as a hanging Grape as it is for forcing and for its earliness.

—— There are, or shortly will be, one or two vacancies for students at Chiswick. Young men who are desirous of availing themselves of the advantages thus offered may receive particulars by applying to Mr. Barron, the Superintendent of the Garden.

—— Major R. Trevor Clarke asks us to correct an error in

our account of the Society's meeting on Tuesday, the 19th. It was *Dyckia rariflora* which he mentioned as having stood several winters, and not Disa grandiflora.

WORK FOR THE WEEK.

KITCHEN GARDEN.

Asparagus, give the beds a slight salting; this should be done after soiling; the rains will carry down the salt from time to time. Attend to the due preparation of the ground for the main crops of *Carrots* and *Parsnips*; endeavour to provide charred materials, half-burnt weeds, or leaves. *Onions* may be sown as soon as possible; choose a piece of ground that has been manured for a previous crop, and, adding no fresh manure, throw it into high beds, sow when dry, cover thinly, and roll as hard as possible. The last advice will, perhaps, not apply so well to clayey soils. *Sea-kale*, plant forthwith, salting and manuring heavily.

FRUIT GARDEN.

Vegetation having been so much checked by the late severe weather, the planting and pruning of fruit trees may be carried on with as much propriety as would have been the case in the beginning of February in forward seasons; but the rapid development which results from a week or two of fine weather at this period should be kept in mind, and every preparation ought to be made for the occurrence of frost. The utility of coping-boards for the protection of the blossom of Peaches and Apricots on walls was mentioned in a former calendar, and in reply to a question on the subject I would mention that only temporary copings were recommended. With the exception of the usual projection of 2 inches of stone or other material of a permanent nature for the protection of the wall, any greater projection is injurious to the trees in summer; but temporary coping-boards about 9 inches wide, afford the blossoms great protection from spring frosts, and when all danger of the latter is over they should be removed. They should be made to fit closely underneath the permanent coping, and should be supported by stays or brackets. If the ground is in good condition plantations of Strawberries may be made. Presuming that the runners of last season were planted out in nursery-beds, and the plants are now taken up with good balls by means of a hollow trowel, carefully planted, and well mulched, crops will be obtained nearly equal in the first season, and superior in the second, to those resulting from an autumn plantation. Bring pruning to a close immediately; root-prune overluxuriant trees, allowing about a foot to every inch of diameter at the base of the trunk—that is to say, for a tree of 4 inches in diameter, open a trench 4 feet off, and so on. Uncover Fig trees, but do not prune them until the buds begin to swell. Prune and nail Vines without delay, stopping the fresh cuts with a patch of white lead.

FLOWER GARDEN.

All grass lawns should now have a thorough rolling, and all turfing repairs must be completed forthwith. Where it is absolutely necessary to edge lines of walks let it be done now, and, as soon as accomplished, run the heavy roller several times up and down the edge to soften the cut line. All edgings should, if possible, have a slight inclination towards the walk, and they should only be fresh cut in consequence of irregularities in the line. High-kept lawns should have a single mowing immediately after rolling. During open weather, like the present, if there are any shrubs that are to be transplanted lose no time in completing the operation. All planting should be finished, if possible, before dry weather sets in. Prune shrubs, Roses, &c., in mild weather. Any ground which has not been dug should be left until it becomes somewhat dry and in a fit state for the operation. Examine rockwork, and dress up any plants that are showing for bloom. Fix any stones that may have become loose. Look over the beds of Pinks, and fasten any plants raised by the frost.

GREENHOUSE AND CONSERVATORY.

Poinsettias done flowering in the conservatory should be removed to other houses at work to make new wood, from which cuttings may be struck. Euphorbia jacquiniæflora may be removed to heat, but not pruned, for if cuttings be an object they will break better without pruning, being liable to bleed. The routine here will now be a constant exchange with the other houses or forcing-pit. Nothing should be allowed to remain unless in blossom or in fine health. Secure, if possible, a small amount of atmospheric moisture without drip. Young plants that are desired to form close, neat, and compact bushes, must have all the strongest shoots topped as soon as they grow 2 inches or so in length. This will cause them to throw out young shoots in all directions. To produce really compact and symmetrical plants it is highly necessary to be very assiduous in carrying out this point of management throughout the whole of the growing season. Some of the strongest-growing kinds, especially of Heaths, may be rendered very interesting specimens, having the form of an elongated narrow cone. This is done by encouraging a leading shoot and stopping-in closely all the lateral twigs. The leading shoot is obtained by pruning back the last year's growth about a third of its length, which induces young shoots, the strongest upper one of which is continued as the leader, and the rest are cut closely in. Plants so treated are very handsome and very appropriate in situations where everything is formal, as, for instance, when placed at regular distances by the side of the pathway in conservatories, or in summer by the side of terrace walks. Those who follow up the cultivation of Pelargoniums should have their plants duly attended to in regard to staking out, &c. They will bear shifting the moment the blossom-buds are formed in the terminal points. Water very moderately after shifting until the pot is half full of roots; those not yet shifted will now require watering freely. Tender annuals, as Balsams, Cockscombs, &c., should now be sown; they will come up better, however, in a frame with a slight heat.

STOVE.

Orchids will now be budding fast; beware of drip lodging in the young buds. Where suspicion exists as to danger in this respect, it is sometimes well to remove some of the old coating which surrounds the bud, by which a free circulation of air is established. The fires should be kept sufficiently lively in the early part of the day to allow of a free circulation of air; every leaf in the house should be dry for an hour or two at midday, after which period the air should be gradually withdrawn and atmospheric moisture removed. This treatment will be found to suit the majority of stove plants as well as Orchids. Many of the Justicias, Eranthemum pulchellum, and some of the Begonias raised from shoot cuttings now and kept growing near the glass in a cool part of the stove all the summer, will make good, dwarf, flowering plants by winter. The cuttings are to be rooted in moist heat. All the following plants will be found very ornamental in the winter months. Eranthemum pulchellum has fine blue flowers; those of Justicia flavicoma or calytricha are yellow; Begonia Martiana is deep rose pink, and the Euphorbia fulgens, Poinsettia pulcherrima, and Aphelandra cristata and aurantiaca are of various shades of red and scarlet. There is a variety of the Poinsettia in which the bracts are white. Here alone are materials enough for no mean display in the winter months.

PITS AND FRAMES.

Attend strictly to watering if the weather continue mild and sunny. Persevere in potting off, sowing seeds, and putting in cuttings of all such plants as are most wanted for bedding out. Give air early every morning, and shut up in the afternoon with a good sun heat if possible. Place in heat Fuchsias, Salvias, Pelargoniums, and Petunias that have not broken shoots since potting last autumn. Pot Ferrarias in light, sandy soil, keeping some for planting out in borders in spring.—W. Keane.

DOINGS OF THE LAST WEEK.

KITCHEN GARDEN.

The work out of doors has chiefly consisted of trenching, digging, and preparing for mending and regulating Box edgings, as, though the weather has been fine and warm, the absence of sun has prevented our heavy ground becoming sufficiently dry to permit of sowing or planting much with propriety. As soon as the state of the ground will permit, preparations will be made for sowing Parsnips, almost the only main crop as to which there need be any anxiety for a few weeks. If early Carrots and Radishes are sown on a warm border, the sowing had better be performed in beds, with ridges of long litter between them from which the droppings have been shaken, in order to cover the beds at night. We escape having to resort to much covering of this kind, by growing most of our earliest Radishes as temporary crops among other vegetables that require longer time, and protection, at least in the earlier period of their growth. Thus the bed from which we are now gathering Radishes was protected with glass during the winter. The next bed has Carrots for the main crop sown in rows, with

Radishes between the rows of Carrots, which will be pulled before the Carrots need the whole space. To succeed these, Radishes are sown between the rows of Potatoes in frames, to be followed by others sown between Potatoes in an earth pit, with a board back and front, on which to rest old sashes or hurdles, the latter thatched or with evergreen boughs drawn through them.

Bottom Heat.—For all such accelerating processes in spring, a little bottom heat is of great importance—that is, a heat ranging from 70° to 75°, and even to 80°, as more than that would be injurious rather than otherwise. This heat we speak of as from 9 to 12 inches below the surface. There is no difficulty in keeping the surface cool enough by the free admission of air. There is little difficulty in securing the requisite bottom heat where there is an abundance of tree leaves and fermenting material from the stables, duly wrought, prepared, and sweetened for the purpose. Where old beds from last season still remain, enough of bottom heat may be obtained for such purposes with but little addition of fresh material, and with little or no previous preparation. Some details respecting such work may be useful to those who are short of material, and wish to make the most of it.

First, as to the two frames filled with Potatoes and Radishes; the bed beneath them was formed of the clearings of the flower garden, Salvias, Ageratums, Calceolarias, &c., with the sweepings of the lawn, the leaves kept chiefly to the surface. These gave out a sweet, mild heat as they slowly decomposed, and the surface of the bed, covered with screenings from the furnaces, helped forward some bedding plants which were just late enough. When room could be found for these plants in the houses, the surface of the bed was stirred, some fresh ashes added; and as the heat was, though mild, too much for plunging Strawberry-pots in, the frames were filled with pots merely set on the surface, each pot being nicely cleaned, decayed and old leaves twisted off, some surface soil removed, and fresh rich compost added. This position gave the Strawberry plants a nice start, and when heat was applied to houses, as Peach-houses, &c., the Strawberry-pots were removed thither. Owing to the roughness of the material, the frames had sunk more at the back than was desirable at this early period; so they were taken off, the bed forked over to the depth of a foot or so, adding a few barrowloads of fresh leaves to give the bed a better slope, the frame put on, nice mellow soil put in, and Potatoes, previously started in pots, planted, and the Radishes sown between. We need not follow these frames further at present. Close to them were two frames set on old hotbeds, now empty, after having contained Lettuces, &c., during winter. We wanted to obtain a little heat beneath the glass of these frames, and could obtain nothing but a couple of loads or so of the litter and dung just as it came from the stables. The frames were lifted off, and all the very rotten material, which could be easily spitted from the outsides of the beds, removed, which left a good sized core, or centre, wet indeed, but not more than half decayed. This was thoroughly mixed with the long, littery, dry dung, the dry and the moist being just sufficient to cause and to keep for a long time a gentle heat from a slow fermentation, and the whole was surfaced with a layer of a few inches of the more than half-rotten material. The frames were replaced, and filled with turves sown with Peas, as noticed last week, and when these are removed the beds will be fit for Potatoes or Beans, or, with the addition of some prepared dung or leaves, for Cucumbers and Melons.

A long earth pit has just been treated much in the same way. Last year about this time, or earlier, that pit, with a board at back and front for sashes to be laid on, hurdles, &c., had about 18 inches of hot fermenting material, chiefly consisting of fresh leaves with a little dung, placed on the bottom, and then soil was put on for Potatoes; and when these were removed, Cucumbers, principally for pickling, were planted, also ridge Cucumbers for table use, Vegetable Marrows, &c. These were followed by late Kidney Beans, which with protection continued to produce till late in November, and then by Cauliflowers taken up from the quarters and put in thickly. The soil in front of the bed had become sodden and soured, so it was removed. A space was also cleared entirely of soil, and an opening made into the fermenting material, now a twelvemonth old. This, though damp, was far from being decayed, and only needed turning and mixing with some fresh material to afford all the heat necessary, the turning itself admitting air and its oxygen to carry on the process of slow combustion, or fermentation. A few loads of this long litter from the stables, and a few barrowloads of fresh leaves, just suited the purpose. As a piece was done and well trodden, mixing the old and the new, the soil from behind was thrown on the part finished, and then what was laid aside at first completed the last part. There is no danger from steam with such an earth covering, and there is the gentle heat beneath which is wanted. A little lime was thrown on the old soil, fresh light loam added, and all mixed together, and the place will be filled with Potatoes before this is in print, and will come in for many purposes afterwards.

We may mention, that in growing Potatoes and Radishes under frames, it is well not to have the soil more than from 6 to 9 inches from the glass at first. This keeps the Radishes short-topped, and as the Potatoes grow the frames can be raised at the four corners on blocks or bricks. In such an earth pit as last described, and of such materials, we may expect the bed to sink gradually about 9 inches before the plants come to maturity, and, therefore, the height at planting-time may be fully 6 inches more than it would be desirable it should be when the Potatoes are full-grown.

These details may help those who would like to have certain vegetables early and cannot afford quantities of sweetened fermenting material. In many cases the heat lost in sweetening might have been utilised, and often we have seen the remains of hotbeds wheeled away when if turned, mingled with fresh litter and dung, and covered over with a part of the old, they would have been quite sufficient for all such purposes as above referred to in winter and spring, and saved many an unavailing complaint about being unable to obtain fermenting material for this or that purpose, and, therefore, being under the necessity of waiting until the ground became warm by the heat of the sun. By such arrangements help can be obtained by heat beneath long before the sun will do much in a similar way.

FRUIT GARDEN.

Went on with pruning, nailing, watching birds, &c., the general work being much the same as in preceding weeks.

Orchard-houses.—As soon as possible we will have these fresh arranged, fresh surfaced, and Peas planted in them. The chief matter we are careful about now is to keep them as cool as possible, with all the air on in safe weather night and day. The longer the blooms are in opening the better we shall like it. The dull weather has also helped to retard the swelling buds. All fruit-buds seem to come earlier than usual this season, whether under glass or in the open air. If we have some bright days soon we shall be tempted, as respects orchard-houses, to dull the colour of the glass a little, by syringing it outside with water coloured by whitening. For the sake of convenience in re-arranging the orchard-houses, we have removed the *Strawberry plants* in pots from them; and what we could not find room for under frames to come on gently, we have plunged in a bed of litter out of doors, and if a severe frost come we can throw a little litter over them, or clean straw. Our plants in pots had too much wet last autumn, but after being dried in the orchard-houses they seem to be all right. Many complaints reach us of the havoc done by the frost in breaking pots, and killing all the outside roots. There is so much trouble in securing good plants in pots that the pots ought to be protected from frost by some means.

It is a long time since we have used fumigating for green fly on Strawberry plants, though we may soon find we are not quite secure, and much of the freedom from insects we attribute to air-giving and a comparatively cool temperature, especially before the fruit is swelling. After that the plants will bear a much higher temperature, but if the air is moist the flavour will be inferior. We should not forget that the plant blooms out of doors early, and the fruit sets when the temperature at night is comparatively low. Had we our will at all times with forced Strawberries, we would never care to have the plants in a higher temperature than from 50° to 55° until the flower-trusses appeared, and never higher when in bloom than 60°, sinking to 55° at night, and rising with sunshine and air to 75°, and a few degrees more if the sun was bright.

ORNAMENTAL DEPARTMENT.

The chief work has been digging, potting, putting in cuttings, and removing plants. Bulbs out of doors will want firming in the soil, and those under glass must be kept near the light to improve the colour. Azaleas, Deutzias, Rhododendrons, Lilacs, &c., will come on fast now if placed in Peach-houses or vineries at work, and just require a warm place in the greenhouse or conservatory when moved there at first. Next month is a good time for potting young plants of deciduous shrubs for forcing, plunging them in a bed during the summer, and mulching with litter until the spring frosts are over. The better such plants are established in the pots, and

the better the wood is ripened early in the autumn, the better will they force in winter and spring.

Securing a Regular Heat by Hot Water, and Making the Most of Fuel.—Of course the furnace-man must learn what every fireplace can do, and the best mode of managing it. The complaints that come to us are chiefly from those who have hot water for small houses, and who either have not enough of piping, not enough of expansion room, have too powerful a boiler, or do not regulate the consumption of fuel by banking up, or the right use of the damper. The complaints are much the same as those which have been partly met in answers to correspondents. A says he will have out his hot-water apparatus and go back to a flue for his little house, as the consumption of fuel is doubled, and his house is generally too hot or too cold, as the fire burns so quickly, and then when it is out the pipes cool quickly. There is B, whose supply-cistern is constantly running over, and to keep the pipes full there is constant water-carrying. Then there is C, who in a small pit has an air-pipe at the highest point of the water-pipes, and several times at night he has just escaped a scalding when walking on the pathway, 2 yards behind, as the boiling water was thrown out in jets, as if from a garden engine. Now most of these evils arise from a greater and a brisker fire than is necessary. It is right to learn from every quarter. A paragraph has been going the round of the papers, telling how Mr. Warren, the celebrated author of "Ten Thousand a-Year," saves fuel, and obtains more heat in his room, by simply placing an iron plate on the bottom bars of the fireplace, the chief use of that plate being to prevent air passing to the fuel directly from beneath. The peculiar advantage of that plate is, that it will become hot, and therefore help to thoroughly consume the fuel next to it. With the exception of the heat from the plate, the same saving of the fuel would be obtained by first allowing the ashes and cinders to accumulate at the bottom to the depth of an inch or so, so as not to permit of air passing up through the bottom bars, the ignition being kept up by the front bars only. We have long acted on this principle, and have gone farther, by placing a brick at the back of the fireplace, so as to keep the fuel more to the front bars, and so throw more heat into the room. Thus, the fire-place in the range in the room in which we are writing is 14 inches long by 9 inches wide, and that might be required at times; but during the coldest days of this winter the space for the fuel was screwed up to 9 inches in length, and a large brick was slipped down behind to throw the fuel more to the front, and, as a rule, the bottom bars were not cleaned out, except at lighting-time, and soon became filled up.

Now, just as in a fireplace it is desirable that no more fuel should be used than would heat the room, so it is desirable that no more firing should be used below a boiler than would give the heat required; and then there is the damper in the chimney to regulate the draught. In addition, however, to the damper and the shut, regulated ashpit-door, much may also be done by regulating the draught of air, if any, through the fire-bars. "D." has just told us that in one of the keen frosty nights he had his house right at 11 o'clock P.M. put on a good fire, as he expected a cold night, went out at 2 A.M., found his house far too hot, and then at 6 A.M. the pipes were cold. Now, by the use of the damper, ashpit-door, and the regulation of the fire-bars, there would be no difficulty when used to the furnace to keep something like a uniform heat in the pipes all night. It is necessary to clear these bars, remove clinkers, &c., on lighting, and this may be required once or twice before banking up for the night, if very coarse material, as breeze and ashy cinders, is used; but when a continuous uniform heat is wanted for the night, and there is already enough of heat in the pipes, flue, &c., then much may be done by patting the fuel down over the bars before adding more, instead of poking it up, and opening vents for letting more air in to supply rapid combustion. In the latter case the fire will speedily burn out, in the former case the fire will be all right in the morning, after giving out a continuous moderate heat all night. With such simple precautions there need be no overheating—no wasting and jetting of next-to-boiling water, however small the place to be heated, if by cistern or otherwise room is left for the natural expansion of water by heat.—R. F.

TRADE CATALOGUES RECEIVED.

F. & A. Dickson & Sons, 106, Eastgate Street, and Upton Nurseries, Chester.—*Catalogue of New and Select Agricultural Seeds, &c.*

J. Backhouse & Son, York.—*Catalogue of Alpine Plants and Hardy Perennials.*

COVENT GARDEN MARKET.—February 27.

Severe as the weather was in the early part of the year, the market gardens furnish us with plenty of the ordinary out-door vegetables. Those of a superior character are supplied in sufficient quantities to keep prices stationary, and consist of good Cornish Broccoli and a superior sort from the Channel Islands. Forced vegetables consist of Kidney Beans, Sea-kale, Asparagus, and Ash-leaved Kidney Potatoes. Pears comprise Ne Plus Meurie, Beurré de Rance, and Easter Beurré. The Potato trade is rather heavy.

TO CORRESPONDENTS.

Landscape Gardener—Storing Apples and Pears (*An Old Subscriber*).—We should not venture to recommend as "the best landscape gardener in Yorkshire," any one whom we happened to estimate so superlatively, but we know of none. If you refer to our No. 271, page 425, published on the 5th of last June, you will find a lengthy answer relative to storing Apples and Pears.

Brown Patches on a Vine (*Guillaume*).—Most probably it is one of the species of scale (Coccus). Paint the stem and branches with a creamy mixture of soft soap and flowers of sulphur, as often detailed in our columns. The spotting of the berries probably arises from the roots of the Vine having descended into an ungenial subsoil; if so, lifting the roots to near the surface, and keeping this well mulched and watered in summer, will be the best treatment.

Microscope (*A Young Botanist*).—The microscope referred to would answer all your purposes as a botanical microscope. The specimens to be examined need no preparation. Apply to any dealer in second-hand optical instruments.

Insectivorous Birds for New Zealand (*A. B.*).—We believe that they are the soft-billed birds which are there in request. Starlings, wrens, wagtails, fly-catchers, hedge-sparrows, &c., would be acceptable. We shall be obliged by information on this subject.

Camellias (*C. Major*).—Either M. Van Houtte or M. Verschaffelt, both of Ghent, could supply you. There is no firm of Langelier in Jersey now. If you send fourteen postage stamps with your address, and order "The Gardener's Year Book," you can have it free from our office by post. It contains the names of nurserymen throughout Europe.

Planting Potatoes (*A Pota Grower*).—On your "hungry sandy soil," we think 2 feet between the rows and 18 inches between the sets would be sufficient.

Potting Azaleas (*J. H. H.*).—It would be well to defer potting the plants until the flowering is over, for if you repot now it is probable that the plants will not flower so well as if the operation were deferred. In potting the ball should not be disturbed; merely remove any loose soil along with the drainage. The soil you purpose using will answer well.

Potting Fuchsias (*Idem*).—The plants should be turned out of the pots, and most of the old soil shaken away. You may then pot them in seven-inch pots, and in a few days afterwards cut them in closely. When the pots are full of roots shift the plants, before the roots become much matted against the sides of the pots, into those 9 inches in diameter, and in the same manner transfer to 11 or 13-inch pots, whichever size you prefer. You may grow the plants to the height you propose this season, pinching the shoots well back to make them bushy.

Hyacinths done Blooming (*Idem*).—You may plant out the pot Hyacinths in a warm open border after blooming, provided you harden them well off.

Applying Lime and Salt (*C. C. Ellison*).—The mixture may be sown over the ground planted with fruit trees of any kind; but it would destroy the leaves of Strawberries, Cabbages, and Lettuces if it fell upon them.

Twelve Annuals for Pots (*C. T. A.*).—You do not say whether you wish them to be hardy, but we presume that you can afford them a little protection, such as that of a south window or frame, from the time of sowing until the plants are up. Oxalis roses, Clintonia pulchella, Acroclinium roseum, Brachycome iberidifolia, Abronia umbellata, Nemesia compacta insignis, Œnothera bistorta Veitchii, Mesembryanthemum tricolor, Portulaca Blensoni, Schizanthus retusus, Amblyolepis setigera, and double Zinnia elegans. These are what are termed half-hardy annuals, and to them may be added Ten-week Stocks, Asters, and Phlox Drummondi, in great variety. If you wish for hardy annuals, then Sweet Alyssum, double Clarkia elegans, Corcopsis marmorata nana, Collinsia bartsiæfolia, Whitlavia grandiflora, Chrysanthemum tricolor, Linum grandiflorum rubrum, Nemophila atomaria oculata, N. insignis, Linaria bipartita splendida, Mignonette, and Mathiola bicornis. For the greenhouse the following are suitable:—Globe Amaranthus in purple, orange, white, and striped varieties; Browallia elata, and its white variety; Thunbergia alata, and its white variety, which are climbers, requiring support; Amaranthus melancholicus ruber, Balsams, Convolvulus mauritanicus, fine for baskets; Egg Plant, purple and white-fruited; and Martynia fragrans.

Pruning Ivy (*W. L.*).—We would defer cutting the Ivy until the end of March or early in April, as if cut now it remains for weeks a very unsightly object. It should be cut with a knife quite close to the wall. Beyond the unsightliness there is nothing to prevent its being cut now.

Anthurium Scherzerianum and Sphærogyne latifolia Culture (*A. B.*).—At this season they both require to be kept in a stove with a temperature of from 60° to 65° at night, which should be increased to 70° by the end of March, and to 80°, 85°, or 90° by day with sun and air. The atmosphere should be kept very moist whilst the plants are growing freely, but not by syringing them overhead, as that impairs their beauty and sometimes destroys it. The moisture, therefore, should be produced by evaporation from tanks or troughs, or by sprinkling the floors, walls, &c., several times a-day. A fair amount of ventilation must be provided, but not in currents, nor should large quantities of air be given irregularly. The situation should be light and not shaded, and there should be plenty of room on all sides. The plants ought to be kept as near the glass as possible; the pots should be well drained, the rough parts of the compost being placed over the crocks to a depth of about 1 inch, or from that to 2 inches. The compost may consist of two-thirds rather light very turfy loam, the top spit of a pasture cut from three-quarters to an inch thick, and either a year old or charred in a hot oven, and one-third turfy sandy peat, chopped and made rather small, but not sifted, to which add one-sixth of the whole of silver sand, and an equal proportion of charcoal in pieces from the size of a pea up to that of a hazel nut, and well incorporated. Water carefully after potting, and when at rest, but when the roots are working in the fresh soil avoid deluging them with water. A slight shade from very bright sun may be afforded for an hour or two during the middle of the day.

Muscat Hamburgh Grapes Shanking (*S. H. J.*).—Shanking is the great fault of this Grape. The heat you name will not save them, but will rather increase the tendency to the evil. All you can do is to have the roots in an inside border, and to encourage and retain more foliage. The best way to treat this Vine when it is planted in an outside border, is to have it worked on the Black Hamburgh.

Maiden-hair Ferns Losing their Fronds (*Idem*).—The cause of the fronds coming very weak and pale, and some of them dying off is your keeping them in a continual state of growth in the temperature of a Cucumber-house. You should have kept them moderately dry in a temperature of about 50° at night, for at least three months of the year, cut down the fronds when these became brown, and placed the plants in a temperature of from 60° to 65°; they would then have become strong. Give them plenty of moisture, do not roast them, and keep them shaded and well watered, but not saturated.

Inserting Mistletoe Seed (*W. W.*).—You may procure the seed from any locality where the plant is found. The seeds are within the berries, and may be squeezed out and inserted in a cut in the bark of the tree, or placed on a smooth part of the bark on the under side of a branch. If placed on the upper side birds are apt to make free with them. Now is a good time to insert them.

Propagating Wellingtonia and Cupressus Lawsoniana from Cuttings (*Idem*).—The best time to put in cuttings of these is towards the end of summer, or when the growths are complete. The young shoots of the current year should be selected, taking them off quite close to the old wood. They should be inserted in pots or pans in silver sand, the base of the cutting resting about half an inch above a layer of loam at the bottom, over the drainage. The pots should be placed in a warm greenhouse or propagating-house, or set in a frame with a mild bottom heat, and should be covered with a bell or hand-glass. The sand must be kept moist. Though plants will grow from cuttings they are not equal to those raised from seed.

Destroying Plantains and Daisies (*Blue*).—The best plan is to grub them up by the root with an old knife. This, though a tedious, is a certain mode of eradicating them.

Angelica Culture (*Idem*).—You may sow the seed in April, in drills 15 inches apart, in good light soil, in an open situation. Do not scatter the seed too thickly, and when the plants are up thin them to 1 foot or 15 inches apart; or you may sow the seed early in August in the same manner, and the plants come into use in the following year. All the routine culture required consists in keeping them free of weeds, giving a dressing of manure in autumn between the rows, and forking it in in spring.

Lilacs Leggy (*W. H. Franks, jun.*).—You will do well to cut out the old stems to the ground with a saw as you propose, and to cut back those left to 4 feet, but if naked at bottom cut them away altogether, and leave those branches coming from the bottom. Do it at once.

Cabbages (*Idem*).—The plants are too young to apply liquid manure to. It should not be given until they begin to heart, and should then be poured between the rows and not on the plants or on their stems. If strong dilute it with water. Urine will not hurt them if mixed with water and other matter. Your plants are eaten at the surface of the ground by what is known to gardeners as the Leather-coat, a dirty grey-coloured grub as you describe it, about an inch long. By taking the soil from around the stems of the plants you may find more of these destructive grubs. Search for and destroy them, the only remedy we know.

Pipes Partially Heating (*Ardavon*).—You do not tell us how you have placed the pipes. We suspect that the side of the house next the boiler has the pipes placed higher than those on the other side that do not heat. Are the pipes at the farther end of the house higher than the end next the boiler? and is there an open air-pipe or small cistern at the farther end? These may make all right. Let us know.

Vinery and Forcing Vines (*H. W.*).—We have looked to the 7th to make sure of your case, and now with the further information we reply:—1, We would keep up the division into two of the 80-feet range, as that will enable you to have the end division next the boiler much earlier if you so wish it. 2, Whenever there is the necessity to keep the water boiling in the pipes, and so boiling over at the supply-cistern, which is placed at the end of the first division, there will soon be waste enough of fuel to purchase extra pipes. If your stop-cocks are right we do not clearly see how the running over a little of the supply-cistern empties the pipes in the farther house. 3, To prevent this running over of the water a larger cistern must be procured, so that when the water is cool it need not stand much above the level of the pipes, and then there will be room for expansion as the water heats. If you fill a teakettle with water the water will run over before the kettle boils, and all the more quickly in proportion to the small quantity of water contained in the kettle, and to the extent of surface exposed to the heating medium; and on the same principle the expansion will take effect more quickly in small pipes than in larger ones, in three-inch pipes than in four-inch pipes. Were you to have double the quantity of piping, or more, you would be less troubled with the water boiling over, and most likely would not require to enlarge the cistern that supplies the pipes. 4, For very early work you would need three three-inch pipes to be added to your present two; or, if it pleased you better, you might make two four-inch pipes answer. For the farther house you might allow it to remain as at present for a late crop; or, if to succeed the first, and pretty early, add one more three-inch pipe to that which you have already. As you have the three-inch piping it would be best to finish with three-inch pipes. They are sooner heated than four-inch pipes, but they are also sooner cooled. 5, Of course the circulation in your first division is complete in itself, and is only prevented going on by the stop-cocks, by which also you regulate the heat in the farther division. If you worked both divisions at once, then your supply-cistern might be at the farther end of the farthest house; but to work them separately you had better allow it to remain where it is. 6, We cannot advise you as to the best and most economical mode of making additions to the piping, as we do not know how your present pipes are placed. The best plan would be to alter your pipes at each end, and connect them with a T-piece, and as many holes in it as you wish to have pipes. Supposing your present two-inch pipes are placed, the flow above the return ° , then suppose you add two pipes, your cheapest plan would be to make the two additional flows where they would stand thus—° ° °, and the two side ones would be connected with the centre one by means of bent one-inch pipes. A similar pipe would connect these again with the one return at the farther end. The best way to do this is to have caps to fit the ends of the three-inch pipes, and have strong inch pipes, one end fastened into a hole cut out of the side of the present flow, and the other end screwed into the socket cap, and the same connecting the additional flows at the farther end with the return-pipe. Thus, with four socket caps and four pieces of one-inch piping, you may connect two more pipes with your present ones with little more trouble than drilling the holes in the present pipes. This plan we know will do very well, but we do not say that it is as good a plan as having all the pipes connected in the usual way, yet it is a very handy one for making additions to the heating medium, as we have several times proved. These caps and one-inch connecting pipes are supplied by all dealers in hot-water piping.

Planting out Forced Strawberries (*E. C.*).—The matter has so often been alluded to by us, that it is hardly necessary to say more than that, as a general rule, we uniformly plant out the greater part of our forced Strawberries, *not* when the fruit is gathered, if that is at all early; but all the earliest plants are generally turned out of their pots against a fence, where they can be protected from changes in the weather by a few branches, or a little rough litter in severe weather. We should not expect much from Strawberry-pots taken out in frosty weather in March from a medium temperature of 60°. All or most of the latest-forced—say in May and June, are generally turned out at once. The earliest would be as well kept in their pots until planted out, but we generally want the pots, and in that case the balls are placed close together, a little leaf mould thrown among them, and a few evergreen boughs kept at hand to protect them from severe frost, and then we generally turn them out in well-stirred and moderately well-enriched soil about the beginning of May. If a few plants do not show fruit at all we generally throw them away at once. The earliest-forced, if thus treated, generally yield some good gatherings in autumn. For extra crops in the following year (that is the forced plants of 1866 bearing out of doors in the summer of 1867), we know of no mode that will equal this for quantity of produce. Such plants, however, do best the first season. They will not be nearly so good in 1868, and very poor in 1869. As far as our experience goes, the first crop from such plants is far superior to that obtained by any other mode the first season after turning out young plants. As stated above, however, the first crop is the only one out of the common way.

Seedling Rhododendrons (*A Lady Gardener*).—The seedlings from the Hybrid Scarlet and other Rhododendrons would certainly produce flowers finer in size and colour than the seedlings or even old plants of the common Rhododendron. If your garden is of limited extent, and only a few plants are required, we would advise the best named sorts only to be planted, though the others would do well for borders. We do not know the Rhododendron respecting which you inquire; but we think Victoria, one of the Hybrid Scarlets, would suit you as to colour, its flowers being of a rich plum or claret crimson hue.

Cutting Back Fig Trees (*An Old Subscriber*).—The best time to do this is when danger from frost is past, and that will be in the early part of May for trees against walls or in the open ground.

Salt for Sea-kale—Running to Seed (*A Cambrian*).—Salt is good for Sea-kale beds; you may sprinkle it over the ground in about half the quantity required to kill weeds on gravel walks, keeping it away from the crowns. When the plants begin to run to seed you will ensure crowns by cutting off the flower-stems at the second or third leaf before they flower. Never allow seed to be produced if you wish for good plants and many crowns.

HEATING AND PLANTING A CONSERVATORY (*G. S. H.*).—The four hot-water pipes would do what you want, but they would do better if they were on the same level; three flows and one return. For Clitoria and Medeola we would substitute Bignonia capensis and Kennedya Marryattæ. For the back wall we would use Acacia armata, and A. Drummondi; and for the ends Passiflora kermesina, Bignonia chirere, Kennedya Comptoniana, and Jasminum samhac. Oranges, Lemons, &c., would do well against such a wall.

EXPENSE OF A GARDEN (*J. S. S.*).—We consider that £16 would be ample for seeds for three acres of kitchen and one and a half acre of pleasure garden, unless you dipped deep into expensive novelties. In ordinary circumstances, about six men under the gardener should manage such a place; but we have great hesitation in giving an opinion, as we have known more men work harder in the space of one acre than the same number of men did in six or seven acres. Much depends on the character of the soil, the succession of flowers, and general cropping, obtaining everything possible from houses, or being content with crops when they come. In most cases an employer can easily judge from seeing how the men work, and the judgment used in setting them to work. We have great faith in activity and industry; we have no faith in mere working long hours, and we know that must be done in some places, and then the desired result may not be secured. Regular hours and adhered to are best for all parties, and then exceptional cases coming seldom will be attended to with zest and pleasure. Our reluctance to give a decision rests very much on what is done. For instance, here is a gem of a lawn, on which there is scarcely a Plantain or Daisy to be seen. To keep that in such a state requires a far greater amount of labour than another where Daisies and Plantains rival and more than rival the grass. We quite agree with you as to coloured earths, &c., as a substitute for flower-beds. When so used the figure looks best when all composed of such coloured materials. Avoid having a bed of flowers and then a bed of coloured earth, nothing will look more incongruous.

CONSTRUCTING A MELON-PIT (*Idem*).—A very good Melon-pit, a lean-to, and useful for general purposes, may be thus constructed:—Width, 8 feet; height at back, 7½ feet; height in front, 4½ feet; path at back, 3 feet, which will admit of several nine-inch shelves being placed against the back wall, which will be useful in winter and spring especially. At the width of the path from the back wall, build another wall, 30 inches or more in height. This will enclose the bed. At the bottom of that have two four-inch pipes, cover them with 4 or 5 inches of open rubble, next with an inch of fine gravel, then with 20 inches of soil. Have two pipes in front for top heat, and train to a trellis, 16 inches from the glass. A first-rate span-roofed house may thus be formed for early and late work:—Width, from 12 to 14 feet; height at sides, wall, 3 feet; height at apex, 8 feet; path down the middle, bed on each side, and heating below and above, as already stated. There will be no necessity for dung; have a trellis for training.

SHADING MATERIAL (*M. R. C.*).—The best material we have tried is tiffany No. 3. It should be tacked to a roller 2½ inches in diameter, a strip of cloth being placed over it, and the tacks passed through both into the wooden roller. The other end of the material should be fastened to a strong lath 2 inches wide and three-quarters of an inch thick, the shred of cloth being used as for the roller to prevent the material coming away in consequence of the nails. This lath should be nailed on the rafters at the upper part of the house, the material being the full width of the house. The roller should be attached to a wooden winder to receive the cord, so that the blind may be wound up or down, wrapping itself around the roller as it is let down, and off when it is wound up; to this the cord should be nailed, and a pulley being fixed at the top of the house, and the cord put through it, the blind may be rolled up or let down at will. It is best put on outside the house, for which purpose only the above plan is eligible.

PLANTS FOR BEDS FROM SEED (*T. Tucker*).—You may fill your beds by sowing seed of the following early next month in a gentle hotbed:—Venidium calendulaceum, yellow; Tagetes signata pumila, yellow; Lobelia erinus speciosa, blue; Calceolaria scabiosæfolia, yellow; Dwarf French Marigold, orange, and striped; Petunia hybrida, various; Ten-week Stocks, the Large-flowering being best; Asters, particularly the Victoria, and Phlox Drummondi in variety. When sufficiently large to handle they should be pricked off and grown on. The following, which require the same treatment—namely, Cineraria maritima, silvery foliage; Perilla nankinensis, brown-bronzed foliage, and Amaranthus melancholicus ruber, with red foliage, you will find useful. Of hardy annuals you may have Sapouaria calabrica, pink, and its white variety; Tropæolum Tom Thumb Beauty, scarlet, crimson, and yellow varieties, and King of Tom Thumbs.

DAHLIAS FOR EXHIBITION (*J. Pritchard*).—The following are first-rate—Leah, deep golden yellow; Ne Plus Ultra, bronzy rose; Charlotte Dorling, white ground, edged and tipped with rosy crimson; Lord Derby, rosy crimson; Andrew Dodds, dark maroon; Bod Ridley, red; Miss Henshaw, white; Anna Keynes, white, tipped with lilac rose; Willie Austin, buff; Criterion, delicate rose; Lilac Queen, lilac; and Beauty of Hilperton, purple.

RAPHANUS CAUDATUS CULTURE (*Tyro*).—Its treatment does not differ from that of the common Radish, only the pods and not the root is the part used. The seeds may be sown in pots in good light soil about the middle of April, and placed in a gentle heat. When the young plants are large enough to handle, they may be potted off singly in small pots; but a better plan is to sow the seeds singly in small pots, and when a few inches high to harden off, and plant out 1 foot apart every way in a sunny, open exposure, the soil being in good heart. This Radish prefers a lightish loam. Water will be necessary during hot weather. The seed may be sown in the open ground in May, or plants may be grown in pots in the greenhouse; for a single plant a nine-inch pot answers well. The height is dependant on the treatment.

PELARGONIUMS (*S. R.*).—*Twelve Select Show.*—*Charles Turner, *John Hoyle, The High Admiral, *William Hoyle, Celeste, British Sailor, *Pretty Mary, Ardens, Conqueror, *Clara, Diadem, and Novelty. *Six Select French Spotted.*—*Butterfly, Neator, *Wallace, *Alphonse Duval, Madame Lelandais, and Eugène Duval. *Six Fancy.*—*Duchess of Somerset, *Silver Mantle, *Clytie, Mrs. Ford, Acme, and The Rover.

TWELVE SELECT SINGLE AND DOUBLE-COROLLAED FUCHSIAS (*Idem*).—*Queen of Whites, *Diadem, *Dreadnought, *Blanchette, *Land of Plenty, *Charming, Excellent, Marvellous, Banks's Beauty, War Eagle, Rose of Denmark, and Sunshine.

SOIL FOR ACACIA DRUMMONDI, ARMATA, AND CHOROZEMAS (*Idem*).—All thrive well in a compost of two-thirds turfy sandy peat, and one-third turfy loam, adding one-sixth of silver sand. Provide good drainage. They require the same treatment as most greenhouse plants, affording them a light and airy situation.

VALLOTA PURPUREA (*Idem*).—Use a compost of turfy loam and one-third leaf mould; afford good drainage, and an abundant supply of water whilst it is growing, with a light and airy situation when at rest, and but little water.

CONVOLVULUS MAURITANICUS FOR BASKET IN GREENHOUSE (*Idem*).—This is one of the best of basket plants. It requires a compost of turfy loam, peat, and leaf mould in equal parts, with a free admixture of sand. The basket should be lined with moss to keep the soil in. Afford a light situation and plenty of water.

PRIMULAS DISEASED (*W.*).—We should remove the whole of the soil, shaking the roots free from it, and repot in entirely fresh soil with a little charcoal or charred material mixed with it.

ROSES FOR HEAVY CLAYEY SOIL (*W. Clay*).—Questions should be more particular. Leaving out Œillet Parfait, a beautiful but tender variegated Rose, all the summer Roses that I have ever had are suitable to any land or climate. No other kind of Roses is equal to or even near to them in adaptation to all soils and climates. I have had these Roses in chalky soil, light loam, and heavy, wet, sandy loam, chiefly ground plants, on Manetti stocks or on their own roots; and, with proper attention, I can recommend them; but, to careless people, I recommend no other Roses than summer Roses on any stock, or autumnals on strong "own" roots. It is ridiculous to suppose an autumnal Rose on its own roots, or on any other stock, without root-protection, could survive such weather as we have had. The power of endurance, however, depends not only on the sort, but also on the condition of the plant. *Hybrid Perpetuals.*—Charles Lefebvre, Jules Margottin, John Hopper, William Griffiths, Baron Prevost, Senateur Vaisse, General Washington, Victor Verdier, Madame Verdier, George Prince, Dr. Andry, Caroline de Sansal, Reine d'Angleterre, Madame Clemence Joigneaux, Vicomte Vigier, Duc de Cazes, Duc de Rohan, Maurice Bernardin, Madame C. Crapelet, Madame Bontin, Maréchal Vaillant, Triomphe de Paris, Jean Goujon, La Ville de St. Denis, Anna Alexieff, Madame L. Carique, Beauty of Waltham, Empereur de Maroc, Madame Julie Daran, Souvenir de Comte Cavour, and Duchess of Norfolk—thirty-one plants; they have wintered beautifully here. *Bourbons.*—Acidalie, Sir J. Paxton, and Bouquet de Flore; under a south wall, Souvenir de la Malmaison. *China.*—Mrs. Bosanquet—the cream. *Tea.*—Sombreuil. *Tea-scented Noisettes.*—Gloire de Dijon and Maréchal Niel, very hardy. *Noisettes.*—Aimée Vibert and Mad. Masson, both small and very pretty; not large enough for show. If land is cold and clayey, it must be drained and rendered lighter for Tea and Tea-scented Roses. All Roses like well-managed clay.—W. F. RADCLYFFE.

CYCLAMEN FLOWERS SMALL (*C. N. B.*).—Without seeing the plants we are unable to say positively whether yours is the same variety as that you saw. From your description we think it was *C. persicum*, the flowers of which vary considerably in size, according to the variety and the mode of cultivation. Not knowing what your treatment is we cannot offer any suggestions.

ORANGE AND LEMON TREES (*L. J. P.*).—Write to Messrs. Rivers, Nurseries, Sawbridgeworth, Harts. If you use blinds for your conservatory tiffany is as good a material as any, but painting the inside of the glass with a solution of size and a little whitening mixed in it is the least inconvenient.

NAMES OF PLANTS (*J. H.*).—No. 1, Spiræa salicifolia, Willow-leaved Spiræa. It is a native of Siberia, but occurs wild in Westmoreland, Cumberland, and elsewhere in England. The seeds are astringent. The other specimen is too imperfect for identification.

METEOROLOGICAL OBSERVATIONS in the Suburbs of London for the Week ending February 26th.

DATE.	BAROMETER.		THERMOMETER.				WIND.	RAIN IN INCHES.	GENERAL REMARKS.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

BREEDING DARK BRAHMA POOTRAS.

Every frequenter of our poultry shows must have noticed the gradual and steady increase in the Brahma classes, showing a correspondingly steady growth in the popularity of the breed. In fact, no breed of fowls has made such rapid progress of late years, and with an utter absence of anything like a "mania," this is a sure evidence that great and real merit is at the bottom of it; and such is certainly the case. As layers Brahmas are in the very first class; as table fowls they are of fair quality, much better than Cochins, though certainly not equal to Dorkings; and as sitters, whilst their behaviour is unexceptionable, it may safely be said of them that the propensity to incubate occurs just often enough to be reliable and useful, without being troublesome. Such merits are quite enough to justify their great and growing popularity, the more so when combined with the very strongest constitution and capacity of bearing confinement of any fowls we know.

The last-mentioned qualities recommend Brahmas most strongly for family use, as the chickens may be reared with facility at any time of year. To illustrate what I mean, I will just say that I hatched on July 31st last year six chickens, of which one perished by accident within a few days. All readers of "our Journal" well know what weather followed that date, yet the chickens had not even the shelter of a shed, my yard being full. They had literally no cover but the board coop in which the mother was confined. In November the smallest of the cockerels was attacked with cramp, and on the 29th of that month was killed, weighing when dead, at barely four months old, precisely 4½ lbs., or much more than some chickens that are reared professedly for the table.

It is, I believe, these solid useful qualities that are bringing the breed so rapidly into repute, and, doubtless, many who this year are beginning to breed Brahmas, will only regard them as so many stock fowls, and make up their yards accordingly; but many, I have been led to believe, will be glad of somewhat more information than they can gather from any published poultry book, and I purpose to lay before such a few dottings respecting the Dark-pencilled variety, which may help, I hope, to a somewhat higher "Standard of Excellence," and be some guide towards success in competition. At the same time I lay no claim to any monopoly of information on the subject, and wherever I may be silent, I shall feel grateful if any one who may have benefited by my knowledge will help me and others with his. There is need for all we can obtain, for I am quite sure that with the exception of the Game fowls, there is no breed which it is so difficult to breed in perfection as the Dark Brahma. Almost every one has a different idea of a perfect bird, and the selection of stock requires the nicest judgment and discrimination.

I would observe, first, that size is a very great point in this breed, and ought to weigh more than it often does, for the consequence of neglecting it is that the standard is degenerating. I was glad, on this account, to see that the judging was greatly determined by weight at Birmingham, though I am no advocate for this ludicrous way of judging a fowl, and have not a word to say for such awards as passed over some of Mr. Boyle's best birds with hardly a notice. All I contend for is, that size should be *one* main point to be considered in judging a pen, and I would call no pen first-class in which the cock did not weigh 13 lbs., and the hens 9 lbs. Good pullets ought to weigh quite 1 lb. per month by the time they are fit to show. I give these, of course, as unfatted weights; if confined and liberally fed Brahmas will make enormous birds, and are often treated so, but are thereby ruined for breeding. The standard I have given used to be often exceeded, and I have now a hen of unexceptionable form and colour, which weighs upwards of 11 lbs. as she runs in the yard. I believe were more attention given to size, such a weight might be ordinarily attained.

Correct form is of the utmost importance, as this breed is one too much contaminated by crosses. The back, especially, should be wide and very short, with a large and ample cushion in the hen. In a good bird this cushion ought to rise nearly from the very bottom of the neck, giving almost no length of back at all, and forming a large protuberant mass of soft feathers, almost hiding the tail. The "fluff" also should be abundant and "stand out" well, so that the tips of the wings should be well tucked in, and almost buried in the fluff and saddle feathers. Very great width and depth of body, without much length, are the points to seek after. The legs cannot be too short or too heavily-feathered, provided they be not vulture-hocked, and it is essential in a first-class bird that they be wide apart. It is disgusting to see so many knock-kneed cocks as often appear in a class, and any bird whose legs do not stand well and firmly apart should never be bred from. I may also remark that "fluff" in the cock is too much neglected. I do not like vulture hock, but it is possible to be *too* much afraid of it.

The neck ought to be short and very taper, a good Brahma head being decidedly small. By far the greater number of the hens I see disgust me by their great, coarse, cruel-looking heads, which are, I believe, derived from the Grey Dorking, and have nothing to do with the true Brahma. The head of a pure-bred Brahma pullet is very small in proportion, of exquisite taper, and the expression, though sprightly, remarkably gentle and pleasing. No test is surer than this one of the *purity* of a strain, whatever its other merits may be. I may also remark that in perfect birds of both sexes, the deaf-ears should fall *below* the wattle; but this is a point which does not now seem much attended to.

Faults in shape to be avoided are—long backs, narrow bodies, long necks, or long legs; and, lastly, let any birds which approach the Cochin type in the narrow and deficient breast be at once discarded. A deep, full, and even protuberant breast is a marked peculiarity of the Brahma breed, and any cock or hen in which it does not appear is of a very inferior order.

The more fancy "points" I must leave till my next communication, but would just observe here, that they must be especially sought in the cock, whilst for size, good form, and shortness of leg, we must chiefly look to the hen. You may have a late-hatched cock, and, consequently, a small one; but if he is good in form, colour, and other points, and of a sound constitution, active and lively, he may breed chickens of the very first class, when mated with good, large, well-formed hens. Small hens, however, you must not breed from, unless you are content to exhibit small chickens. On the other hand, if the hen be large and well-proportioned, she is not to be discarded for a slight fault of feathering or comb. If the cock be good in these, a large proportion of the chickens will be all they should be.

As Brahmas are very largely kept and bred in confinement, I will add one more caution: Do not let your breeding birds become *fat*. This is the one great difficulty of amateurs with limited space, all the larger breeds having a great tendency to lay on too much flesh when kept in confinement. Such will never breed fine large chickens—the system is overloaded. Give your birds enough, but no more. Keep them so that they shall always have a good appetite. A pen of breeding birds, to afford the best results, should always look rather thin, but not, of course, very much so; and if any reader have tremendous hens which lay small eggs, let him herein learn the reason, but by no means fly to the other extreme and starve them in revenge. Such is by no means the meaning of—Nemo.

(To be continued.)

BREEDING GAME FOWLS.

(*Continued from page* 153.)

In breeding in-and-in, too close breeding is, of course, objectionable, such as breeding from father and daughter, from mother and son, and from brother and sister; of the three, the last is the best, but all three are unnatural. A person breeding only one strain or colour should have two breeding walks or runs, and should change the cocks from one run to the other, for doing so crosses the birds a little. A good cross of the same colour every five years is a good plan, but one every ten years is quite sufficient, and is, perhaps, the most correct way of breeding with really good birds, which would spoil by too frequent crossing.

A valuable brood cock may be bred from until he is eight or nine years old, by keeping him from any hens from midsummer until Christmas, in a good walk either by himself or along with all the cock chickens and young stags, which he will prevent from fighting, separating them himself directly they commence hostilities. His spurs must, of course, be blunted, or he might kill the young birds while separating them in their frequent battles. As soon as the "stags' heels," or spurs of the young cocks begin to grow sharp, these should be taken from the old cock's walk, dubbed, and put out to a walk, each

separately of course. The old breeders for the pit found this plan answer remarkably well, and they kept their brood hens with the young pullets in the same way in another good run. This prevents both cocks and hens from exhausting nature when eggs are not required for breeding-purposes. The crossing of different colours is absurd, and is only practised by inferior breeders. No pure-bred birds can be obtained from crossing colours.—Newmarket.

(To be continued.)

THE LONG FIRM AGAIN.

A person who gave his name and address as "J. R. Reid, 54, Pott Street, New Islington, Manchester," replied to an advertisement of mine in The Journal of Horticulture, and, after a short correspondence, he agreed to have the birds at my price. I was to send them off at once, and a post-office order would be sent on their arrival. I wrote, asking for a post-office order on the usual terms, but did not hear further from "J. R. Reid." I also obtained information through the Tradesmen's Protection Society; the answer was short and to the point. I am given to understand the Long Firm are very busy just now, and are obtaining a great many goods from unwary persons. The letters have printed headings, some of them with more than one address. I hope these few lines may be the means of putting some one on his guard.—Joseph Walker, *Haya Park, Knaresborough.*

NEW INCUBATOR.

Mr. Brindley makes a serious error when he assumes, that because he left an incubator at 102° at 10 p.m., and found it at 100° the following morning, the temperature therein had not varied more than 2° during the night. Had he used maximum and minimum thermometers he would probably have found that the variation had, in fact, been very considerable, and that at 4 or 5 a.m., the coldest period in the twenty-four hours, the thermometer had fallen to 94° or 92°, though it rose again to 100° by 8 a.m. I speak advisedly on this point, as I have just concluded a series of important experiments, carefully carried out, on the construction of incubators.

I have succeeded in constructing an incubator that works perfectly, and in which the variation of temperature is entirely overcome.

I found it quite impossible in a Brindley incubator to keep the water always at the right temperature, and my own method is, to keep boiling water always circulating in the pipes, and to have the pipes moveable, so that I can withdraw them to any distance out of the incubating-boxes, so as to allow a difference in the quantity of piping used in winter and in summer. Further, my incubator is fitted with a glass steam-pipe, and a steam-dome for the collection and dispersion of the steam; and a small supply-cistern is attached to the boiler, by which the latter is always kept full, the height of the water in the supply-cistern being always shown in the glass tube. The water being always boiling, the heat never varies over the eggs, and the only watching required is occasionally to add some water to the supply-cistern.

I find that I have made my incubator very cheaply, and its practical working is very perfect.—A. H. S. W.

TRANSFORMATION OF COMB.

I am obliged to "A Devonshire Bee-keeper" for his reply to my question regarding brood remaining undeveloped (see page 60), and I may mention that I am not aware of any of the hives referred to having ever fallen a victim to foul brood. They commonly dwindled away till not a bee was left.

In reference to the transformation of drone comb into worker and *vice versâ*, I will give one instance of many, with a quotation from an esteemed correspondent and a first-class apiarian.

In 1866 there was a scarcity of drones in my apiary (Italians). I furnished a hive with comb, more than one-half being drone comb, for the purpose, if possible, of raising some drones, from a swarm that I tenanted therein. After hiving, the weather became very fine, and much honey was stored, the combs being completely filled, so that not a single drone was hatched. I was somewhat sanguine that the subsequent spring would find this stock with plenty of drones, and more so when I observed drones in it so early as January; but, to my mortification, as the spring advanced not a single drone appeared. Swarming time arrived, and very few drones appeared. When I examined the hive the whole of the drone comb had disappeared, and there was worker comb in its place. Evidently enough it had been transformed. The following is an extract from the letter to which I have allnded:—

"I may mention that in experimenting with bees I think it highly essential to imitate nature as nearly as one can in every point, and I do think you were ahead of the reason in attempting queen-rearing so early. I will just state one instance which occurred in my own apiary two weeks ago. Being anxious to start queen-rearing as early as I saw drone eggs laid, I procured some fine drone comb from ——; I fitted it into a hive where my best queen was, and on inspecting it ten days afterwards I was mortified to find it transformed into worker comb, and eggs laid in every cell."

If apiarians who have had experience on this subject would state their evidence they would oblige—A Lanarkshire Bee-keeper.

[I trust my Lanarkshire friend will not esteem me too exacting if I confess that I have still some doubts as to the disposition of bees to transform drone into worker comb, and *vice versâ*. I do not for one moment question the accuracy of the incidents which he relates, but I am inclined to believe that he is mistaken in considering that the inserted combs were destroyed only *because* they were drone combs, and that if worker combs of the same character as to age, &c., had been inserted, they would have met the same fate in being destroyed and rebuilt, although in this case no transformation would have taken place. I have witnessed more than one instance in which bees have in the spring absolutely refused to accept strange worker combs, although in first-rate condition, but have at once set to work to either wholly or partially destroy and rebuild them. I once removed the queen from a stock which had partially destroyed a worker comb, and the result was a most curious piece of mosaic or patchwork, all the vacancies existing at the time being filled with drone cells. This is, of course, an instance in which worker was transformed into drone comb, but it can scarcely be said to have been intentional on the part of the bees, which if left to themselves would simply have replaced the old worker cells by new ones, the transformation which was effected being entirely attributable to the removal of the queen before the renewals were completed.—A Devonshire Bee-keeper.]

REMOVING OLD COMBS, &c.

In the autumn of 1865 I purchased four stocks of bees at a sale. One of them was in a Nutt's collateral hive, though not so complete in its construction as described in Neighbour's "Apiary;" the other three were in common hives, two of them pierced at top for glass supers, and one not. The stock in Nutt's hive had been there at least two seasons before it came into my possession, the middle box alone being occupied, although communication with the two outside boxes was left free by the former owner, either from design or his not being properly acquainted with their management. Last summer, after swarming, the bees filled one of the side boxes. I also placed a glass super over the middle box, but without effect. Late in the autumn I removed the glass and closed the aperture. At the present time the stock appears strong, occupying the side box filled last summer. The combs in the central box are black and empty. Ought they not to be removed? and would it not be advisable to do so before the bees commence active operations?

From the other three stocks I obtained strong swarms, which were placed in new hives. After swarming, the stock in the old hive not pierced for a super, appeared to grow weaker, but not having had any experience in the manipulation of bees, I allowed them to remain, and they have since died out. The other two were removed into the bee-house; one of them hived in the summer previous to my purchase is strong and the hive sound, and I propose leaving it another season to obtain a swarm. The other is much older, the hive is injured by exposure, and the stock not strong. It is desirable to remove the bees into a new hive. Can I effect this by simply opening the aperture at the top and placing the hive over it, taking care to prevent egress between the hives? Is it likely the bees would occupy the new hive of their own accord, or

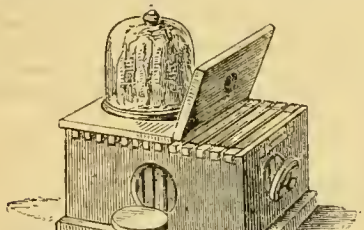
must I have recourse to the process called driving, which I fear I am not skilful enough to accomplish?—Adolphus H. Kent.

[If the combs in the "pavilion" are very old, it may be better to remove them, and in that case it should be done before it is re-occupied by the bees. It is, however, quite contrary to rule to permit a side-box to become the stock-box; and if the combs in the centre compartment are not more than two years old, we should suspect some error in management. It may possibly have resulted merely from an entrance in the side-box being left open until the bees had come to use it as the main doorway, in which case the seat of breeding would most naturally become established in close proximity to it. The stock in the common hive had, doubtless, become queenless, a not-uncommon accident after swarming, but one that is apt to escape observation in common hives until the colony has become nearly extinct. You had better permit the stock in the decaying hive to swarm, and three weeks after the issue of the first swarm, when all the brood will have been hatched, drive out the remaining bees and add them to some other colony. The plan which you propose would not answer.]

PETTITT'S NEW MOVEABLE COMB-HIVES.

This hive has just been brought out by Mr. W. J. Pettitt, of Dover. It contains thirteen bar-frames on the seven-eighth-inch or Woodbury scale, and the top bar of each projects quite through the back and front of the hive, resting in the metallic bar-rest precisely similar to the "Sibert-in-the-Wold" plan. Each frame is 13⅛ by 8⅜ inches, the actual size of the combs, and the elongated top bar enables the bee-keeper to loosen the frames previous to the removal of the crown-board without thrusting the finger and thumb into the hive.

The thirteen frames can all be used at the same time if desired, or by means of a dividing-frame which fits into the place of any one of the bar-frames, the actual size of the hive can be contracted or enlarged at pleasure, and if placed in the ninth "rest," it then gives a complete stock-hive with eight bar-frames.



Pettitt's New Moveable Comb Hive.

A Bar-frame.

The crown-board is in two parts, as shown in the engraving, is connected by brass hinges, and separates immediately over the dividing-frame in the ninth rest. The remaining four frames can be used as a collateral-super, communication to which is given through the dividing-frame from the stock hive, over which a bell-glass or other super can be worked; while the smaller division of the hive can be operated upon by lifting a portion of the crown-board without opening the whole hive or in any way disturbing the glass super upon the top. Empty frames can be easily exchanged for newly-made combs. The bees generally commence working in the frame nearest the stock, consequently that frame will be the first to be removed from the hive. I advise the removal of this comb as soon as finished; then shift the three remaining frames, and put in the empty frame quite at the end of the hive; and this process can be repeated as long as the honey season continues.

The top bar of the frame in this hive is cut away, as shown in the engraving, allowing a three-eighth-inch space between it and the crown-board, giving room for the bees to travel over, except about 1 inch at each end, upon which the crown-board rests and holds the frames securely in their places. That portion of the crown-board which covers the four spare frames is provided with a ventilator exactly similar to that in the top of the supers in Pettitt's collateral hives.

This hive has the peculiar advantage of being worked both on the storifying and the collateral system, retaining at the same time all the advantages of the bar-frame arrangement.—Sudbury.

PRODUCTION OF CREAM.

Experiment has proved that if we take two equal quantities of milk, and place one in pans to the depth of 6 inches, and the other to the depth of only 2½ inches, the latter will yield from 7 to 8 per cent. more cream than the former. This is the case more particularly in cold and damp weather, and at this time the mistake is most commonly committed. The temperature of the surrounding air has also a great effect upon the time required for the rising of the cream; experiment has demonstrated that the process is more rapid in warm than in cold weather. With the thermometer at

80°,	all the cream will rise in	10	hours	55°,	all the cream will rise in	24	hours
77°	"	12	"	50°	"	36	"
68°	"	18	"	45°	"	43	"

Sprengel found that if milk was kept at a temperature as low as 37°, but little cream would rise in three weeks. In order to avoid the trouble of keeping the cream at the proper temperature, it is customary in some dairies to churn the whole milk. The advantages claimed by those who follow this plan may be briefly stated thus: The proper temperature can be readily obtained both in summer and winter; 5 per cent. more butter can be obtained from the same milk; the butter is not only of the same quality while fresh, but if properly managed will keep much better.—(*Germantown Telegraph.*)

OUR LETTER BOX.

Colours of Yellow Birchen Hen (*A Subscriber*).—The true yellow Birchen hen has yellow or daw eyes, and yellow legs like the cock. The general colour of the feathers is a yellowish grey, with a strong tinge of yellowish cream colour all over, the feathers being edged with black. Breast, a yellowish greyish cream colour, light rather than dark; some of the margins of the feathers on the body are of a whitish cream colour also. Thighs as the breast. Tail blackish, a little marked with grey at the base. Comb and face red. Eggs of a yellowish tinge, and never white or pinkish. This is now a rare colour.—Newmarket.

Distinguishing the Age of Golden-pencilled Hamburghs (*Subscriber*).—We are so satisfied that there are no rules to guide us in distinguishing the age of fowls after they have passed the first year, that we do not attempt to name any. A very old hen can be distinguished from one that is only eighteen months old; but there are no means of distinguishing between those eighteen months and three years old. Some people talk of the scales of the legs and the wrinkled careworn faces, also the coarse wrinkled skins. All these exist, but they belong to no particular age. Even those who live by poultry live and dead are frequently deceived.

Perches for Fowls (*M. L. A.*).—Perches should not be more than 30 inches from the ground; they are as effectual, so far as the comfort of the bird is concerned, as if they were 20 feet high. A fir pole 14 inches in circumference, and split in the middle, is the best material, and the round side should be uppermost.

Proportion of Ducks to One Drake (*Idem*).—Four Ducks are enough for a drake, though some put more. There is no method of making a hen sit.

Cochin-Chinas not Laying (*F. S.*).—We can assign no cause for your disappointment. Cochin-Chinas are unquestionably good layers, and as for their sitting properties, if we were to allow the poultry world to deposit their greatest grievance in a heap made up of all, we should find in two months' time nearly all the Cochin fanciers throwing down broody hens; retrospect and anticipation both show us three or four heaps of buff feathers thrust into a laying box, growling when touched, and resisting everything short of actual violence to remove them. If the eggs were unproductive, it was caused by the fact that the cock did not attend to them. This is not so uncommon as it is sometimes supposed to be. You have been very unfortunate, but there is no rule to explain your failure.

Saccharine Food for Poultry (*Locust Beans*).—We have never tried saccharine matters as poultry food, and we should not like to. We have always found the most satisfactory food to be barley and oatmeal. We are driven to Indian corn because we are infested or benefited by myriads of small birds, and, while we find them in corn, our neighbours have the benefit of their useful labours. We are, nevertheless, sure that Indian corn is not so good as either barley or oatmeal. The best food there is is the oatmeal used in Sussex. It is made of the whole corn, ground so fine that it mixes as well as flour; nothing whatever is taken from it, no husk, bran, or anything else. We believe it is only to be had in Sussex.

Bee Gloves (*G. J., Birmingham*).—Indian-rubber gloves such as are used by photographers are the best for apiarian purposes. They are sold at most indian-rubber warehouses at, we believe, 5*s.* to 6*s.* per pair.

Gold Fish in an Aquarium (*Abbots Wood*).—Gold fish do best in soft water. If the tank is large, and there is plenty of vegetation in good order, the water is best seldom changed, but filled up as it evaporates. Watercress is not good—it will not live. The pond weed Anacharis alsinastrum, Valisneria spiralis, and Ranunculus aquatilis are good for the purpose; and to keep the glass clear from the confervæ, put half a dozen flat water snails in, Planorbis corneus. The fish do not require much food; give them small worms, they being the best, and occasionally a little bread and boiled rice, its grains kept separate, but not in sufficient quantity to lie at the bottom of the tank. Let some drift sand be in the aquarium.

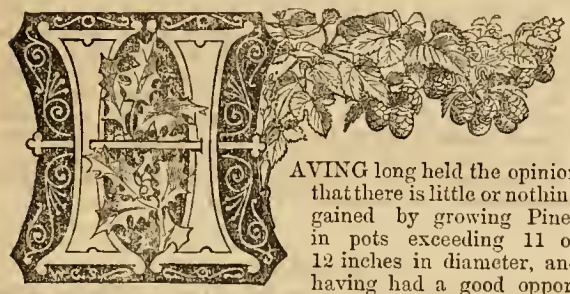
From observations taken near London during the last forty years, the average day temperature of the week is 49.8°; and its night temperature 32.3°. The greatest heat was 67°, on the 12th, 1841; and the lowest cold 7°, on the 10th, 1847. The greatest fall of rain was 0.69 inch.

SMALL VERSUS LARGE POTS IN PINE APPLE CULTURE.



HAVING long held the opinion that there is little or nothing gained by growing Pines in pots exceeding 11 or 12 inches in diameter, and having had a good opportunity of testing the two systems in the production of the supply of Pines here during the winter of 1866–7, I have thought the result might interest some of the readers of THE JOURNAL OF HORTICULTURE.

In the spring of 1866 I found the plants intended for the winter supply in a more forward condition than usual, and than I wished them to be. I therefore, contrary to my usual practice, decided on shifting a portion of them into 16-inch pots, with the view of keeping the plants growing and, consequently, preventing them from starting till July. This was done on the 22nd of February, and the plants selected for the shift were the strongest and those having their pots the best filled with roots. The plants constituting the portion left unshifted were mostly in 11-inch pots and a few in 12-inch pots, and from these I would not have expected such large fruit under any circumstances as from those which were shifted into the large pots. The latter were in all respects the finest plants.

The fruit from the whole of these plants, forty-eight in number, were cut between the end of October, 1866, and the end of January, 1867, and to show the results I append the respective weights of twelve from 16-inch pots and twelve from 11 and 12-inch pots :—

16-inch Pots.	lbs.	oz	11 and 12-inch Pots.	lbs.	oz
Smooth-leaved Cayenne	9	6	Smooth-leaved Cayenne	9	2
,, ,,	9	1	,, ,,	8	12
,, ,,	8	9	,, ,,	8	11
Charlotte Rothschild ..	8	5	,, ,,	7	11
Smooth-leaved Cayenne	8	3	,, ,,	7	10
,, ,,	8	3	,, ,,	7	1
,, ,,	8	2	,, ,,	6	12
,, ,,	8	0	,, ,,	6	10
,, ,,	7	9	,, ,,	6	8
,, ,,	7	7	,, ,,	6	7
Charlotte Rothschild ..	7	5	,, ,,	6	7
Smooth-leaved Cayenne	7	4	,, ,,	6	6

At first sight it may appear to those not conversant with Pine-culture that something considerable was gained by shifting into the 16-inch pots, but it must be borne in mind that all the finest plants were selected for the largest pots—plants from which, whether they had been shifted or not, I would have looked for the finest fruit; so that in respect to the production of large fruit, I consider little, or indeed nothing, was gained by the shift. Of the other twenty-four fruit there were only eight under 6 lbs., and their respective weights did not tell, any more than the weights given, in favour of the large pots.—D. THOMSON, *Archerfield Gardens.*

PLANTING PEAR TREES.

QUINCE AND PEAR STOCKS.

THANKING "C. C. E." for his friendly, able, and timely remarks on the above subject at page 85, I, as one of the parties interested, beg to give an answer to his question, "What is to be done?"

I, like "C. C. E.," have had trees of the Pear on the Quince stock from a first-class nursery worked 6 or 8 inches above the roots. Only last March, and again in November last, we had a number of trees, some worked 2 inches, and others between that and 10 inches, above the roots, whilst a few had been worked so low that the junction of the stock and scion had been covered with soil, evidently at the time of performing the operation of grafting; these had not rooted from the graft. The trees are five or six years old. Now, I planted all so that the fibres were covered with 3 inches of soil irrespective of the height at which the trees had been worked, and immediately after planting gave each a mulching of well-rotted cowdung 2 or 3 inches thick all round the stem to a distance of 2 feet from it. This is what I did last year and in previous years, and what I recommended Vol. XI., page 460.

"C. C. E." asks—1st, "The limit of distance between the graft and roots." I would prefer the trees worked as near the ground as practicable, and not exceeding 3 inches above the roots. The trees would then be eligible for all soils and situations; the junction could be covered, which I recommend to be done on all but heavy wet soils (for on shallow, dry, light soils the rooting from the graft or Pear is an advantage rather than a disadvantage), or the junction could be left uncovered, soil being placed to within the least possible distance of the junction of the stock and graft, which is desirable, as the certain rooting of the Pear would tend to wood growth, and on such heavy wet soils the good offices of the Quince in causing a dwarfer growth, fertility, and an earlier ripening of the crop, are destroyed.

2nd, "Should trees grafted 6 or 8 inches or more above the roots be rejected?" Yes, if those not worked more than 3 inches above the roots are procurable; but if such cannot be had, and only those that have been worked 6 or 8 inches or more above the ground are to be obtained, my answer is, No. Plant them so that the roots will be covered 3 inches with soil.

3rd, "Should trees grafted on the Quince stock 6 or 8 inches above the roots have these buried, or should the tree be planted up to the junction of the stock and graft?" Well, no; the roots should not in any case be covered more deeply than 3 inches. When these are deeply covered the shoots are long, sappy, and generally badly matured; but when near the surface the probability is the wood will be short and well ripened.

4th, "If the roots are not to be buried, is the stock to be hidebound?" No. Soil should be piled up against the stem so as to entirely cover the exposed portion of the

stock; this should be done in spring after planting, and the base of the cone need not extend farther from the stem than the height of the cone. The roots are not in that case buried, the stem is not hidebound, and roots are emitted from the covered portion of the stem. An annual addition of rich soil or manure all around causes an extension of the cone, and the roots from the stem are near the surface, whilst the original roots are not buried, for their annual extension carries them farther from the stem, their fibres being all the while covered no deeper than if the stem were uncovered. Trees treated in this manner bear as well as those which have been worked nearer the ground, and they have two sets of roots, neither of them in their most important parts buried too deeply; in fact, the trees have roots nearer the surface than those having one set of roots only. I do not, however, recommend such trees; for in lifting, the original roots, from their greater distance from the stem, have their fibres cut off, and the parts are too deeply covered to form fibrous roots: hence the inutility of the original roots, and though they may emit new fibres, these must inevitably be destroyed at every lifting of the trees. Such trees should always be planted high.

As to "C. C. E.'s" other questions, "Whether Pears on their own roots, and Apples on the Crab, are not better than on the Quince and Paradise stocks," I think there can be no two opinions on the subject, the choice being solely determined by the size the trees are to attain and the soil they are to grow in, as "C. C. E." remarks, but he should add, also by the culture they are to receive. I will now state my opinion on these subjects so far as my experience warrants.

With regard to the Quince as a stock for the Pear. 1st, The disposition of its roots is more shallow: hence it is better adapted for thin soils, also for planting where the subsoil is of an unfavourable character, such as a wet, undrained, stiff clay, impregnated with iron. On shallow soils the Quince, having its roots near the surface, can be fed by rich top-dressings, and, as its roots do not descend into the subsoil, the trees do not die of canker as when the Pear stock is employed where the subsoil is calculated to produce that evil. In thin soils, however, the Pear on the Quince should be planted on a raised mound, which secures roots near the surface, and any loss of moisture and coolness can be counterbalanced by rich surface-dressings, copious supplies of water, and liquid manure occasionally in dry weather. Further, the shallow disposition of the Quince roots is in its favour where the situation and soil are low and wet, because Pear trees in such soil root deeply, and abundance of wood is produced; but the prospect of a crop is small, and if canker do not commence the trunk and branches of the tree are plentifully covered with moss. The Quince on such soils is quite at home, requiring only to be planted on a mound or hillock twice as high as where the soil is shallow—that is, in a wet soil the tree should be planted on a mound twice the height of the roots, measuring from the uppermost fibres to the base, which distance on an average I find to be 9 inches: hence the mound should be from 1 foot to 15 inches above the ground level, whilst on shallow soils the trees may be placed on the ground, and the roots covered with soil.

2nd, The tree is more dwarf in growth. This is an incalculable advantage. An amateur with but a few square yards of open ground can have his Pear trees. They do not grow so vigorously as to smother everything else, and though small and occupying but little space, he has not to wait years for the fruit; whilst if he were to plant trees on the Pear stock he would probably have no more than room for one tree, growing well, no doubt, but years must elapse before it can furnish an abundance of fruit, and that coming in all at one time. On the Quince the trees fruit in a year or two at most, and as they occupy less space, several varieties may be grown so as to afford a successional supply.

3rd, The Quince will grow and thrive where the Pear will not. In a cold wet situation Pears on the Quince will ripen fruit when those on the Pear stock will scarcely ever do so. This result arises from the roots of the Quince tree being nearer the surface, and consequently in a warmer medium; moreover, the Quince is of earlier growth than the Pear. There is no soil in which the Quince will not thrive with careful culture. Heavy clays, it is true, are not congenial to it any more than to the Pear. On dry, sandy soil it soon cankers the trees upon it, unless liberal top-dressings and plentiful supplies of water and liquid manure are afforded; but it flourishes in a rich, rather light soil with a wet bottom, in which the Pear cannot be profitably grown.

4th, Trees upon the Quince come into bearing sooner than those on the Pear stock, and the fruit is larger and better ripened. Upon the Quince, Pear trees come into bearing in the first or second year after planting, and produce as many fruit annually, in proportion to their size, as a full-sized tree, and they are capable of bearing one to two pecks of fruit by the time trees on the Pear stock come into bearing; besides, the fruit is seldom if ever so fine from trees on the Pear stock as from those on the Quince in the open ground. The increase in the size and colour of fruit grown on the Quince is due to the returning sap receiving a check when it reaches the Quince; indeed, the effect of the latter is similar to that of ringing.—G. Abbey.

(To be continued.)

POTATOES FOR THE FAR NORTH.

"Monticola" has "a farm of five hundred acres, on a light, dry soil, in a cold county in the north, and finds his Potato crop has been deteriorating for many years, because he believes the seed has never been changed," and he is quite right in the supposition.

This garden is between two and three hundred years old; it has certainly been chiefly cultivated with Potatoes by me upwards of twenty years, and last season the crop grown in it was as good in quantity, and I may say better in quality than ever. Two of the sorts—viz., the old Walnut-leaved Kidney, and the old Fortyfold (second early), I have grown on the same spot during the whole of the time; but, then, I never fail to change my seed every year. The ground is a stiff, hearty loam, and I take care to procure my seed from light soil, or one of as opposite a nature as possible, from a place as near as convenient, but not always from the same field, and twice during the twenty years I have had quite fresh stock of the above two kinds, once from Suffolk, and once from Devonshire. By so doing there is no limit to the time that Potatoes may be grown good and profitably on the same ground, provided it is properly dug, hastard-trenched, or subsoil-ploughed often, and kept in good heart.

The sorts I recommended in my "Gossip" of February 14th, for field culture, &c., are good for cultivation on almost any soil. I procured them, or have had them presented to me, with many other sorts, at different times, from all parts of England. I selected the kinds there described, as being what I consider, after trying them by growth and palate, of superior excellence to the general run. I did not intend it to be inferred by my so doing, that so many sorts must necessarily be cultivated by each individual, but merely as an index pointing out the way for others who might be in need of information or guidance, on the presumption that one or more of the sorts might be known, or intelligence gained of them, in different neighbourhoods.

"Monticola" wants but one good market sort, and he turned to the printed list of a contemporary, where he found to his surprise only one sort that I recommended, the York Regent, quoted there, along with Flukes and Regents from various Scotch counties. I do not by any means consider the York Regent a Potato of the first quality, but I recommend it as being a popular market sort, which can be grown anywhere, and is easy to be procured. There are many kinds of Flukes sold which are simply bad. I happen to have kept the old variety by me for many years. Walker's Scotch Regent, and Sutton's Finest Regent, are very good, far superior to the old York Regent; but the Gryffe Castle Seedling stands at the head of all the Regents. I should think "Monticola" can easily procure this sort. It was sent to me about five years ago from Scotland, along with some other famous Scotch Potatoes, in a Stewarton bar-and frame bee hive, by an unknown friend, "a brother bee-keeper." It is stated at page 423, No. 297, to have been grown at Gryffe Castle, Renfrewshire, last season, at the rate of "223 bags, weighing nett 22 tons 5½ cwts. per acre, quality first-rate, flavour excellent, causing quite a run for seed in the spring." That is the Potato for "Monticola." As a summer sort I would advise a trial of Daintree's Seedling Round; it is a kind scarcely to be distinguished from the Dalmahoy in appearance, and whilst growing, but it is superior in flavour, looks better at table, and takes less time to cook. Then he could send a first-class Potato into the market "all the year round"—viz., Daintree's, followed by the Gryffe Castle.

"Monticola" also requests me to "name the best Potato for the Hebridean cotter." Without a moment's hesitation, I say the Freebearer of the east, *alias* Grammar of the north,

alias Late Fortyfold of the south and west, *alias* Red Breadfruit of the midland counties. It is also sometimes called "Rough Red" in the north, but do not let the old Scotch Rough Red be mistaken for it; the latter is red all over, and ugly, too, but the Freebearer is uglier still, having very deep eyes, and it is of a mottled purplish red and white. The flesh is quite white, of excellent flavour, and it is of a rare quality for "laying on" the flesh of pigs, and bringing down the scales. Whether the land be wet or dry, it is one of the very best Potatoes for the cottager, particularly where the ground is manured with "seaware," or vraic. I have helped to collect it for the purpose in Jersey for many a long hour.—Upwards and Onwards.

RENOVATING OLD WALNUTS—VENTILATING VINERY.

I am desirous to make known a discovery I have made—that Walnuts, after being kept for two or three years, and until so dried up that you would suppose you were handling empty shells, are restored to a perfect state by steeping them in water for a couple of days, and allowing them to remain one or two days longer out of the water before using them. Foreign Walnuts, which have a thicker shell, require longer immersion, say about three days. I have some of the latter at the present time that I prepare as a dainty for my canaries, and such look and feel as well, and are, I think, as well-flavoured as the first hour they were gathered. If you think it worth while to publish this in your Journal I shall feel that I may have suggested an agreeable after-dinner occupation to a considerable extent.

I have been greatly interested for some time past in the many and various articles in your very interesting Journal on the subject of the Vine; it is, in my opinion, a subject that never wearies. I am myself a little of an experimentalist. I began to use lime rubbish and oyster-shells in the composition of my Vine borders many years ago, and in addition to this I add a considerable quantity of charcoal, a substance which is beginning to be appreciated by the gardening world, but I think it is not so extensively used as it deserves to be.

My vinery is constructed after a plan of my own; the roof and about two-thirds of the front being glass, with about 1 foot of galvanised wire netting next the ground in front, which supplies a constant ventilation, and my Grapes are often pronounced better than most hothouse Grapes. I have not yet had any artificial heat, but this year I intend to have Hays's patent stove to give a few weeks of warmth in the early part of spring, and I am all anxiety in case of a sunless summer.—T. M. Robson, *Penally*.

TREES NOT INJURED BY GAME.

For "E. F. G.'s" information, I am sorry to say that very few trees and shrubs are not liable to such injury.

I happen to be in one of those places where game is reared on a large scale; I should think last year there were 1500 rabbits on about one hundred acres, and hares and pheasants in proportion. The only trees and shrubs which I do not remember the game to have injured, are the Beech and Birch, Alder, Black Thorn, common Thorns, Elms, Willows, Deciduous Berberis, Dogwood, common Laurel, Portugal Laurel, Rhododendrons, Ribes, Snowberry, Sweet Briar, Wild Raspberry, Yew, and Gueldres Rose.

The following may, however, be planted with safety, if care be taken in very severe weather to paint the stems with cowdung, soot, and clay, or to bind some Gorse round them. Some trees and shrubs, however, are so bushy that it is impossible to get at their stems without damaging the branches; but those which I shall now name I have never found injured by game, except in very severe weather, when a little extra feeding for a short time with Swedes for rabbits and hares, will often prevent damage. These are—Acacia, Ash, Aralias, Evergreen Berberis, Cercis or Judas Tree, Cherries, Horse Chestnut, Hornbeam, Maple, Oak, Poplar, Prunus, Rhus, Ribes, Spiræas, Sycamore, Syringas, Viburnums, Walnuts, Weigelas, Andromedas, Abies, Aucubas, Box, Cedars, Holly, and Loniceras. Perhaps there are a few more which I have omitted; I only write from experience.—T. Elcome, *Rhug Gardens*.

Chimonanthus grandiflorus.—I was not aware of any special merit due to a propagator for obtaining the above from cuttings; for several years ago I had cuttings put in in two successive years, and nearly every cutting rooted and made a plant in the following year. The cuttings were put in about the same time as those you mention, and were of the current year's wood, but taken from the tree with a small shoulder of old wood.—T.

FLOWERS AND THEIR ASSOCIATIONS.

There is a common saying, "Call a Rose by whatever name you will, it is still a Rose;" and when we have expended all our enthusiasm flowers are but flowers, the frailest, yet the most beautiful things earth holds in her keeping. Dear they are to most, if not to all of us. Few have the courage to acknowledge insensibility to their transient charms. Some may live away from their influence in the centre of a large town, where flowers grow not, where they are seldom seen; but this very rarity gives to their beauty a power which is often dimmed by constant sight and usage. And then, too, their power, beauty, and influence vary to each of us. Time, circumstances, and associations give a deeper, sometimes a very painful interest to individual plants and flowers, connecting them indissolubly with the events of our passing years, with our joys and sorrows, with our heavy losses, with our long weary hours of work, with our longer and more weary hours of waiting, with our misunderstandings and separations, which fret the spirit, and leave life-long heart-burnings; with our hasty outspoken words of anger, which fill us with gnawing regret; with days of sickness, of painful suffering when the hands lie useless, and the aching head feels like Tennyson's "Deserted House," empty quite, for thought is not—cannot be; and with that deeper misery, that misery which is so hard to bear—the sense of utter failure, and cold neglect, and unforgiven faults.

Yes, full of associations to some one or other are most of the every-day common flowers. Some minds may feel less of this than others, but all in some measure. That field of Buttercups and Daisies burning beneath the June sun—a marvel of beauty, making the costly garden within the park gates pale in comparison, and seeming like very cloth of gold set with silver stars—brings back to the mind fields of long ago, where truant children, caring nothing for torn or soiled clothes, wandered, climbing over gates and walls to gather the forbidden flowers, and wishing the days were weeks long, and wondering, like the little school boy wading knee deep in Wood Anemones, if heaven would be half as lovely.

Those little Speedwells, how dear they are to us yet! and how beautiful they were growing in the soft grass of that home meadow, a long broad patch of blue—intensely blue—a bit of the summer sky come down to dwell upon the earth, never to be seen in after-years without a yearning desire for the home, the hedge, and the meadow.

Those deep pink Cabbage Roses which we stood watering one July evening in the near-to-town garden, watering with much noise and mirth, when the tidings of a great grief reached us, never looked the same after; the spirit of unconscious beauty seemed driven away, and you might have thought sorrow had entered in, for they hung down their heads as if weary of their own weight; and though we cared for them and grew them afterwards, we never loved them, and never could entirely separate them from the trouble of that summer evening.

And the Heliotrope—I never see it or catch a passing breath of it, but I think of one Heliotrope before which the thought of all other Heliotropes fades away—an old plant sending out its perfume into a dingy parlour, where a mother, growing old faster than her plant, sat watching and waiting for her son's return. Oh, the bursts of passionate grief and anger! The poisoned words come back to memory ever with the Heliotrope—cannot be parted from it—leave ever a sense of pain which even its sweet fragrance cannot banish.

"Maud, dear, do not give Polly those Wallflowers, I cannot endure the smell of them," said a young mother to me. "They remind me so of poor Edith, though she has been buried more than fifteen years; she died early in the spring, and we could get nothing but Wallflowers to put into her coffin. I have never liked them since; I know it is foolish—mother says it is wicked—but I cannot help it. I cannot bear them. I never go into the market during April or May for fear I should see them, or smell them. I cannot think whatever they do with the immense quantities of cut Wallflowers they bring in. If I had miles of garden I would not grow one; they make me live over again that dreadful time—fill me full of unpleasant memories." And yet when Mrs. Crompton

died her daughter went up and down trying to get a few sprigs of late Wallflowers. She had costly stove flowers offered by her friends; they would not do for her—she said her poor mother knew nothing about them, did not love them, and that flowers were almost worthless save for the thoughts and feelings they embodied.

"Those Orange Lilies remind me of the prairies of America," said one who had wandered up and down on the face of the earth. "I never see them but I go back to that old time when, travelling in North America out among the wilds, we used to come suddenly upon them growing in the hollows, large patches of them one brilliant glow. Ours are pale in comparison; the stronger light, I suppose, brought out a deeper colour."

That little Oncidium flexuosum, standing out like an "In Memoriam," the gift of one—a brave, strong, yet ailing, delicate man—who thought for, worked for, and gave up his life for, the elder brother less brave, less strong, who lay down in the midnight darkness to sleep with miles of wood, and field, and lonely moor all around—lay down with his day's work unfinished, the hope of his life unfulfilled, and never woke up in this world to finish his work; and his hope we can but trust he will find in that other country where the hands are stronger, and the pains of the flesh hold not back the willing worker.

So it is, some flowers are much to us apart from their beauty and their fragrance; they are breathings-out of the life we have lived, reminders of the scenes through which we have passed, sharers of our mirth and revelry, quiet witnesses of our sad and solemn hours, untired tellers of the old story of our doings; and fresh and new with each season do they come back to us.

Again, we are digging away the snow in the old Abbey garden miles from home, to find the Snowdrops we knew were above the ground before the storm came, and we shiver at the east wind blowing keenly through us, and feel the deadly coldness of the but-half-alive flowers when found and gathered. We can see them with our eyes closed, and know very well all the Snowdrops in the world can never be to us what those poor far-fetched delicate spring flowers were.

Or we are seeking with untiring patience the dark Primroses from among the pale ones, growing on that Primrose bank at Gothorp Hall, that bank on which the sun loved to shine; and we can hear the murmur of the dear river Aire, that used to make sweet music for us; and we can feel the hushed stillness from the great Rommell's Moor tracking our steps, making a sort of presence which awed our childhood, causing us to pause, and listen, and wait. Ah me! there was no fear in those days, no jarring note in the hallelujah chorus of our lives, no thunder in the heavy rain clouds darkening all the villages around, no danger in the wind that whirled and tossed the leaves and straws high up above our heads, and rolled us over and over on our grassy play-ground. Now we never see those spring flowers in cottage gardens, or growing under the hedges, or in the market in the countrywomen's baskets or on the artist's canvas, but we think of those who were about us then, who never more will hear the murmur of the river or the deep breathings of the moor.

Or we are dragging and poking up with bits of rough sticks great yellow bulbs of the Turk's Cap Lily growing in a little garden of an empty house. How we pulled, and toiled, and overheated ourselves on that close August evening, and bore away in our fright only two roots. The house had an evil name—was, indeed, said to be haunted, so that we pulled, and poked, and worked in mortal terror of the ghosts inside, and in dread of some chance passer-by, for it was a roadside garden.

Or we are twisting and turning long sprays of Bindweed round our hats, and wondering why the big white flowers should persist in closing up so long before the day is done, and trying out-of-the-way means to keep them open, at last tossing them away to float down the stream like fairy gondolas. Now, in our wiser years, we never pluck them, but leave them to open out wide and full in adoration to the warm summer sun, the only thing they care for; when he moves westward or shades his splendour, even for an hour, they fade and die.

Or in our summer holidays we are again picking pale pink Convolvuluses out of the short stiff grass—real shore flowers we call them; but we never gather them without dreaming of a time when we lay resting on a warm hillside with those little flowers all about us; a sense of peace, and rest, and joy filling our hearts, loving friends with true and tender words making richer and fuller the cup of our lives, and the great waves like giant crystals beating up to Bridport Harbour—silent save for the fishermen's cries—the blue sky brooding softly over a sea as blue.

"I never can look at Primulas," said a dear cousin, "but I grieve for the fate of one that came to an untimely end—a finely-fringed white Chinese Primrose brought all the way from that far country by a captain friend—a splendid specimen. It was watered and tended so carefully, and flowered as never Primula flowered before for nine long months; then in my absence it was turned over in the darkness and left to die."

Then, too, those little Forget-me-nots—how full they are of many memories of wild-flower gatherings—in the Middleton woods, in the Adel valley on the banks of the Ouse, on York Common, in the Shipley glen, and in the Dorsetshire lanes; but clearer than all else stands out the thought of a Sunday evening ramble outside the town of Dorchester, beyond the long avenue of trees that mark its entrance so grandly. There we stood in the grass beneath the cool grey sky, for the day was nearly done, a group of girls gathering Forget-me-nots for each other to be kept safe and live till we should meet again, gathering them with low, soft, loving words mingled with kisses and gushes of laughter that would not be kept back. I can see again the summer day fading into the night, our dresses falling on the grass, blending with its greenness, and making but one colour; and I can hear the fall of our feet homewards, and the sighs with which we put away our treasures—prestige of the sorrow of a long, long parting. And when the living blue Forget-me-not comes to me (I never seek it now, or grow it, or care to go where it is), then I look at my grey dead ones, and feel a deep aching meaning in those words,

"Oh, for the touch of a hand . . . . and the sound of a voice."

Or we are dropping quiet, painless, nay, thankful tears, upon some fair white flowers, sister flowers to some we left upon a new grave—a grave dearer and sadder than we think any other can ever be to us; left in all their fresh beauty and sweet fragrance upon the dead flowers of other years, upon the grassy mound in that old churchyard, the rooks cawing in the dark Fir trees, the noise and smoke of the great town far away, and the warm soft August rain dropping down tears quieter even than our own upon our fair white Lilies. Dear and sacred are those Lilies unto us.

Yes, so it is. A flower may be but a frail flower, and yet it may be invested with a deeper meaning, made richer by the doings and feelings of a life. To many the pale Snowdrops are but the herald of spring, born out of the cold hard winter soil—promise of gayer flowers to follow. To others they are the world's resurrection flowers—not born, but risen from the dead—a thing of the past linked to the far future. And some flowers which we may regard with sorrowful eyes may be to others full of sunny memories, of pleasant associations: so that after all they are what we have made them, speaking to us in the language our own lives have taught them, but yet ever dear to us—dear in the long summer days of peace and joy—dearer still in the cold winter days of sorrow and loss, unless, indeed, we have suffered the noise of the great world to deafen us to their low sweet voices.—Maud.

VERBENA CULTURE.

I should like to recommend, side by side with the remarks made on the Verbena by Mr. Wills, a plan which I adopt for growing them after they are struck, and which, if not original, is not common. No doubt some one will start up and say, "I have practised it for many years!" and if any of your readers do so, I have no doubt the plan has never been abandoned by them. It is as follows:—

After the cuttings are struck, say at the end of March, a frame about 18 inches high at the back and a foot high in front is chosen; one that you can shut up perfectly close is the best. Inside the frame place 9 inches of good light soil, and in this plant the Verbenas from the cutting-pots, watering them well with tepid water to settle the soil. When the sun shines, every morning give about half an inch of air, no more, until ten o'clock, when the plants should be watered overhead, and shut up closely for the day. The thermometer will possibly rise above 100°; but you will see, if you try the system, what a black strong growth the plants will make in consequence. When you see a warm genial shower coming in April or May pull off your lights, and expose the plants to it, shutting them up

as soon as it is over, if it is after the time named above; keep them well stopped, and harden them off a fortnight before planting out.

Amaranthus and Perilla also do very well in this way, and so will Coleus I believe, although I have not tried it. The plan described saves much of the watering that would otherwise be necessary, and is the easiest I have fallen in with.

I confess I laughed outright when Mr. Wills told us not to water a plant after potting until the roots had reached the sides of the pots; but then I am—An Essex Calf.

HARDY FLOWERS IN JANUARY AND FEBRUARY.

Bitton, near Bristol.—I send my list of hardy plants in flower during the months of January and February, arranged according to your suggestion; and I hope to be able to forward you a similar list every month.—H. N. E.

JANUARY.

Jan. 1.	Helleborus niger	Jan. 1.	Wallflowers.
,,	niger major	,,	Gorse
,,	odorus (dumetorum)	,,	Cydonia japonica
,,	atrorubens	,,	Viburnum tinus
,,	olympicus	,,	Erica herbacea
,,	fœtidus	,,	Arabis præcox
,,	Daphne hybrida	,,	Eranthis hyemalis
,,	Neja gracilis	,,	Hepatica, white
,,	Chimonanthus fragrans	,,	Violets, Russian
,,	Daisies, single and double	Jan. 7.	Aubrietia deltoidea
,,	Potentilla alba	,,	Omphalodes verna
,,	Primrose, red	Jan. 23.	Leucojum vernum
,,	Azara dentata	,,	Cyclamen ibericum
,,	Veronica Andersoni	,,	ibericum album
,,	Jasminum nudiflorum	,,	Crocus Imperati
,,	Lonicera fragrantissima	Jan. 27.	Galanthus nivalis
,,	Tussilago fragrans	,,	Crocus mœsiacus
,,	Lamium maculatum	Jan. 29.	Cyclamen coum
,,	Garrya elliptica	,,	Crocus vernus

FEBRUARY.

Feb. 7.	Scilla sibirica	Feb. 20.	Double Snowdrop
,,	Hazel	,,	Crocus stristus
Feb. 10.	Helleborus orientalis	,,	concinnus
Feb. 14.	Scilla bifiora	,,	obesus
,,	Anemone pavonina	,,	Berberis Bealii
,,	Galanthus plicatus	Feb. 23.	Forsythia suspensa
,,	Hepatica, red, single and double	,,	Buxus sempervirens
,,	Hepatica, blue, single and double	,,	Arabis albida
,,	Crocus Sieberi	,,	Narcissus maximus
,,	Hyacinthus romanus	,,	pseudo-Narcissus
Feb. 17.	Ranunculus gramineus	,,	Primula denticulata
,,	Ficaria ranunculoides plena	,,	Sisyrinchium grandiflorum
,,	Ficaria ranunculoides alba	,,	Saxifraga oppositifolia
,,	Helleborus purpurascens	,,	Polygala chamæbuxus
,,	Erica conioides	,,	Petasites alba
,,	Crocus vernus	,,	Daphne mezereum
,,	sulphureus	,,	Ranunculus ficaria
,,	lagenæflorus	Feb. 26.	Hyacinthus orientalis
		,,	Forsythia viridissima
		,,	Saxifraga ciliaris

BATH.

Feb. 1.	Dandelion	Feb. 20.	Caltha palustris
2.	Daisy	20.	Coltsfoot
2.	Primroses	20.	Ground Ivy
8.	Hepatica	21.	Lungwort
13.	Celandine	24.	Large Periwinkle
14.	Wallflower	27.	Daffodil
16.	Pyrus japonica		

—S. B. C. V.

Middlesborough-on-Tees.—I send you the names of a few flowers that bloomed here during the past month.

The effects of the late winter are more apparent than they were a month ago. I find two specimens of Cedrus deodara of about ten years' growth very much injured, and a Cedar of Lebanon of about the same age quite browned. A Wellingtonia of the same age does not appear to have suffered in the least. Evergreen Oaks have suffered much; I am afraid we shall have to take some of them down. Photinia serrulata and Clethra alnifolia have succumbed. Plants in flower:—

Feb. 1.	Snowdrops	Feb. 12.	Siberian Rhododendron
,,	Single and double Violets	,,	Crocus
,,	Mezereon	Feb. 20.	Australian Wallflower
,,	Pansies	,,	White Arabis
Feb. 7.	Hepaticas	,,	Bearsfoot
,,	Spring Bulbocodium	Feb. 22.	Scilla sibirica
,,	Mediterranean Heath	,,	Berberis
,,	Omphalodes	,,	Yew
,,	Buttercups		

—M. H., *Acklam Hall.*

Haddington.—Plants in flower—Winter Aconite, Snowdrops, Primroses, Hepatica, and Polyanthus. All bulbous plants, long kept back, are now (February 11th), vigorously pushing through the ground.—John Ferme.

ROYAL HORTICULTURAL SOCIETY.

March 6th.

Floral Committee.—This meeting, although not equal to the last, was a very interesting one. The supply of Orchids, considering the inclement weather, was excellent; and many other interesting plants were exhibited. Among the plants brought before the Committee were some extraordinarily fine specimens of the Large-flowering Mignonette, exhibited by the Rev. G. Cheere, Papworth Hall, St. Ives. Six specimens were sent; a single plant in each 48-pot, actually a mass of bloom. The cultivation of this simple plant was the admiration not only of the ladies, who were delighted with its perfume, but we might almost say the envy of the nurserymen. The seeds, we understand, were sown last August, and no liquid manure was used, merely a little bone dust in the soil at the time of potting. The seeds were sown in pans, and the seedlings potted in thumb pots, and then transferred to the five-inch pots. A special certificate was awarded to Mr. Cheere, also the same award for some fine specimens of Anne Boleyn Pink. Messrs. Veitch & Sons, with their usual liberality, contributed largely to the exhibition. A first-class certificate was awarded to Lælia Pilcheri, one of Mr. Dominy's hybrids, an Orchid of much beauty, the dark rosy purple lip being very conspicuous. Special certificates were awarded for Cymbidium eburneum, Cœlogyne cristata, and for the general collection, in which were some very choice Orchids; also Achyranthes Verschaffelti aureo-reticulata, a new form of Iresine; Camellia Storyi, Trichopilia suavis, &c. Mr. Hodges, gardener to E. Wright, Esq., exhibited cut specimens of a new Lycaste, with singular dark brown side petals. Mr. Parks, gardener to G. Cooper, Esq., Old Kent Road, brought three beautiful specimens of Phalænopsis Schilleriana, distinct varieties, well grown, with unusually large flowers. A special certificate was awarded them, and the Committee recommended them to the Council for the Lindley medal, which recommendation was entered on the minutes of the day. Nothing but an ardent love of horticulture could have induced the owner of these plants to have exhibited them in such a cold day; we much fear the plants will suffer from the change of temperature. Mr. Bull also largely contributed to the exhibition from his select collection of plants. Among them a novelty in the stove plants, Dalechampia Roezliana rosea, attracted much attention. The small clusters of almost insignificant flowers are placed between two bright rosy bracts, which remain bright in colour for six weeks, and when the flowers have died away the bracts still give a cheerful appearance to the plant. At first sight it was a perfect puzzle to imagine what family it belonged to, and much surprise was expressed by the uninitiated to find it among the Euphorbiaceæ: a first-class certificate was awarded it. Among other specimens Mr. Bull sent a new fine-foliaged plant, Samyda nobilis; also some small specimens of Odontoglossum gloriosum and O. Alexandræ: a special certificate was awarded the collection. Messrs. E. G. Henderson sent small collections of their admirable Cyclamens and Primula sinensis; some of the double varieties of the latter were very pretty. A curious specimen of Cyclamen, producing red and white flowers from the same plant, excited some sensation. A special certificate was awarded the collections. Mr. G. Warren, gardener to T. J. Levett, Esq., sent a cut specimen of an old favourite, Epidendron mucrochilum. A collection of superb cut Orchids was sent by J. Bateman, Esq., which received a special certificate. A cut specimen of a most superb plant, Brownea grandiceps, was sent by Sir Hugh Williams, Bodelwyddan, Flintshire. This was perhaps the most striking specimen exhibited, as the plant has seldom been seen in flower. A special certificate was awarded. A collection of Orchids was sent from the Society's gardens, also cut specimens of Camellia reticulata. We much missed specimens of Camellias, and cannot understand why the cultivators of this beautiful and popular winter flower do not exhibit them.

Fruit Committee.—Prizes were offered on this occasion respectively for the best three dishes of Dessert and of Kitchen Apples, and were awarded to Mr. Whiting, The Deepdene, Dorking. His Dessert Apples were Adams's Pearmain, Mickleham Pearmain, and a kind unnamed, but which had some resemblance to Federal Pearmain; the Kitchen varieties were Alfriston, Devonshire Buckland, and a late kitchen Apple unnamed, but believed to be London Pippin. The whole of Mr. Whiting's fruit were well grown, and in excellent preservation. Mr. S. Ford, gardener to W. E. Hubbard, Esq., St. Leonard's Lodge, Horsham, sent three seedling Apples, which, however, were not considered of sufficient merit to deserve a certificate; and from Mr. George Lee, Clevedon, Bristol, came specimens of Apples produced on the same tree, but very different in appearance, one being a Russet, whilst the others (Orange Pearmain), had a smooth bright crimson skin. Respecting this singular fact some remarks were made by Mr. Berkeley at the meeting in the afternoon. Mr. Stanton, gardener to J. Bateman, Esq., Biddulph Grange, sent a dish of home-grown Oranges, also Lemons, one of which was very large; and Mr. Sherratt, gardener to the same gentleman, at Knypersley, bunches of Ahbee Grape, referred to in our report of the fortnightly meeting.

Mr. Wells, Holme Lacy Gardens, submitted what he believed to be a variety of Sea-kale, with yellow instead of purple tops to the leafstalks, but the Committee did not consider it distinct. From Mr. Earley, gardener to F. Pryor, Esq., Digswell, came Hamburgh Perennial Spinach, which proved to be only the old Patience Dock or Herb Patience.

Fortnightly Meeting.—Sir Philip De Malpas Grey Egerton, Bart., in the chair. After the election of thirteen new Fellows, and the admission into union of the Sorbie Parish Cottage Gardening Society, and Wotton-under-Edge Horticultural Society, the Rev. M. J. Berkeley offered remarks on some of the subjects exhibited.

Mr. Berkeley first remarked, that the plant with pretty white flowers shown at the last meeting by Mr. Earley, and which was said to produce red berries, proved to be Trichosanthes colubrina, and that, therefore, its bearing berries was a mistake. He then noticed Messrs. Henderson's Cyclamens which were deservedly much admired, and more particularly one which produced white and rose-coloured flowers, the former also very different from the latter in structure. Most of the varieties were said to be crosses between C. coum and C. persicum. The peculiar structure of the pretty Dalechampia, from Mr. Bull, was then noticed, and some remarks were made on the Herb Patience, which had been sent as Spinach, instead of which it is still used on the Continent, though now almost obsolete in English gardens. The remarkable flower of Brownea grandiceps, from the garden of Sir Hugh Williams next occupied attention, and Mr. Berkeley remarked that in a natural state the flowers are pendent. Dr. Lindley, who figured in the "Botanical Register," in 1841, a specimen flowered by Richard Harrison, Esq., of Liverpool, related a circumstance which he (Mr. Berkeley) did not think had since been verified. Dr. Lindley, writing of the blossoms, said, "They are produced in a short spike, tier above tier; every day witnessed the expansion of a new tier above those of the former days, till at last the whole mass became a globe of living and glowing crimson. This brilliant head appeared on the side of the main stem among the leaves, which at that time presented a singular phenomenon. Every evening they rose up and lifted themselves from the blossoms to expose them to the dew, so that each morning these beautiful objects were uncovered; but as day advanced the leaves gradually drooped, and bent down over the flowers to guard them from the rays of the sun." Mr. Berkeley added that he did not think this circumstance had been observed since, although the plant, which was related to the Amherstia nobilis and Jonesia asoca, had been flowered at Chatsworth, Glasnevin, and other places. The plant at Bodelwyddan was of considerable age, and the house in which it was grown had been raised twice or thrice to give it room. He might also mention that Lady Williams was the daughter of the Earl and Countess of Amherst, in honour of whom and of her mother the Amherstia had been named. Mr. Berkeley next referred to the Apples sent by Mr. Lee, of Clevedon, and which were produced on the same branch of a tree of Orange Pearmain. The branch was about 4 feet long, and the Russet-looking fruit was produced near its base. The circumstance of the two kinds of fruit being borne on the same branch called to mind a plant well known to most cultivators, Cytisus Adami, which is generally believed to have been produced by grafting Cytisus purpureus on the Laburnum, and, by some accident, one cell of the stock and one of the graft having each become divided and then united together, the result had been a plant partaking of the nature of both. It would be very interesting to know what stock Mr. Lee's Orange Pearmain was grafted on, and whether this was another case similar to Cytisus Adami. Passing to another subject, Mr. Berkeley said he had received a letter from Mr. Arthur Trollope on raising seedless Grapes, and suggesting crossing varieties which have no seeds, such as the Sultana and Black Monukka, with the view of obtaining an early seedless race of high flavour; but Mr. Berkeley said he could not recommend the Sultana, as the berries were too far apart, but if a seedless Hamburgh could be produced it would be a great acquisition. Mr. Trollope also drew attention to another curious matter—namely, that if such Grapes could be produced the vital energy of the Vine would be employed in producing pulp instead of being diverted to the formation of seeds, and hence that finer fruit would be the result. [Some remarks on this subject will be found at page 385 of our last Volume.]

Major R. Trevor Clarke said that Mr. Berkeley's remarks on that curious, paradoxical plant, Cytisus Adami, had recalled to his recollection the fact that he had a plant of it many years ago, which not only produced seeds from the flowers of the yellow Laburnum and Purple Cytisus, but from the intermediate form as well. In those seasons in which the latter perfected seeds he noticed that the flower-stalks were persistent, remaining green during the winter, and from every place from which a flower had fallen a small shoot was produced, which in every case was that of the Purple Cytisus. At the last Tuesday meeting, said Major Clarke, he had occasion to mention the hardy nature of Pyckia rariflora, a plant belonging to a family, perhaps one of the last we should look to for such a tendency, the Bromeliads being tropical or semi-tropical plants, but it was undoubtedly hardy in a warm place. He now produced another member of the same class which had stood one winter covered only with a handful of moss, and more than this, it flowered strongly in the succeeding summer. In the spring following the next or second winter, the main stem or crown was found to have perished, but a small sucker remained alive, and did in fact grow on healthily till destroyed by accident. He was not quite certain of the name of the plant, but he thought it belonged to the section of Bromeliads called Puya. Another of them, and a very fine one, P. Altensteinii, grew freely with him in the open air during the summer. Then he had another, quite a little pet, but he was not sure of the hardiness of this member of the family; and he next produced another specimen of the same plant which had been wintered in the greenhouse, and which was consequently dormant, but it would flower by-and-by in the warm summer time even in the greenhouse or conservatory. Two other Bromeliads, Bilbergia purpurea and an old zebra-striped plant of which he had forgotten the name, served to make up a little collection of interesting tropical plants grown in common moss—three of them at least greenhouse plants as to habit, two hardy under careful treatment, and all thriving in glass cases kept in a sitting-room. He had also brought with him a cut spike of an old African plant, Antholyza præalta, a most picturesque plant, but rarely seen in flower. Unfortunately its habit of beginning to grow at the end of the year and producing its blossoms in early spring, added to a total inability to stand a few degrees of frost, will always be against its cultivation in the open air, except in the south of England or in very favourable spots near the seaside. He well remembered the fine effect of some patches of it in the garden of the Chiaya, at Naples, on one fine February sunset. The next morning every plant was killed by frost. He mentioned this because every now and then the Antholyzas cropped out in the catalogues as plants cultivable out of doors.

Mr. Bateman said he was indebted to the Society for the opportunity of presenting to them a Grape introduced from the Deccan by Colonel Sykes, and called Ahbee, and it was well deserving of attention on account of its property of keeping so late in the season. It was now March, and though there were a few Grapes such as Lady Downe's and Barbarossa that would keep till then, still he did not know a better Grape than Ahbee at the present season, as it was still exceedingly juicy. Though certainly not equal to Mr. Kelk's Muscats exhibited two years ago, in fact, nothing to compare with them in flavour, it was really a most desirable variety to grow on account of its late keeping; besides which, it had another merit in its colour being so very lovely. Till he had seen this Grape he had never believed in the tints of the old Dutch pictures; but of what beautiful tints there were in the vegetable kingdom there was abundant proof around, and the only question was, Could these tints be copied?—and to that question he found an answer in a book (Knoop's "Pomologia"), in which though now more than a hundred years old, the colours were as fresh as when they came from the studio of the artist. For the opportunity of seeing this book they had to thank Mr. Bohn, who had found it out and given it to Dr. Hogg.

Among Orchids, remarked Mr. Bateman, there was a flower-spike of the white variety of Epidendrum macrochilum which had been grown in a Pine-stove by Mr. Warren, gardener to T. J. Levett, Esq., Wichnor Park, Burton-on-Trent. Every one knew that Orchids generally could not be grown successfully in Pine-stoves, as such structures are too warm and dry; still there were some salamanders, and the Epidendrum in question, coming from the hot climate of Caraccas, was one of them. Among novelties, with the exception of a new Lycaste from Mr. Wright, of Gravelly Hill, Birmingham, and Lælia Pilcheri, one of Mr. Dominy's hybrids, there was not much. He might remark of Dendrobium luteolum, from his own garden, that it was only beginning to fight its way into notice, and that next year he hoped to be able to exhibit it with a dozen spikes in a pot. Mr. Bull's Cypripediums were then referred to, and nothing, Mr. Bateman said, would please him better than to see ten or twenty species shown at the same time, for there were as many as a score of species already in this country. Of Odontoglossum Alexandræ, of which two or three small plants came from Mr. Bull, it was remarked that it is one of the easiest of Orchids to flower. Cœlogyne cristata from Messrs. Veitch was a most meritorious example of good cultivation, being quite a cascade of flowers. It was one of those Orchids which he termed bridal Orchids, and in cultivation required to be kept cool to flower well. Another beautiful Orchid of the same class and requiring similar treatment was Cymbidium eburneum, which had the merit of continuing a long time in flower. Messrs. Veitch had also a remarkable spike of the golden-flowered Dendrobium Farmeri, and one or two good Cattleyas—among them Cattleya Trianæi, a name which, as stated at the previous meeting, could not be retained. One other of Messrs. Veitch's plants was the lovely and sweet-scented Trichopilia suavis, to which a painful association was attached, for it had been sent to this country by Von Warscewiez, to whom we are also indebted for Trichopilia coccinea and other Orchids. After remarking on the news of Warscewicz's death following so soon after the loss of Mr. Skinner having become known, Mr. Bateman said that although Warscewicz had travelled over a great portion of New Grenada, Quito, and Peru, he had not left us more than half a dozen plants; not because he was not indefatigable, but owing to our ignorance of how to treat those which he sent home, most of which required a cooler treatment than that which had been afforded them, and they consequently perished. There was one other plant which must be mentioned, the lovely Phalænopsis Schilleriana, exhibited by Mr. Cooper, after whom had been named at the last meeting Epidendrum Cooperianum. Though he (Mr. Bateman), had seen as good plants, he had never seen the flowers of that Phalænopsis so large and so beautiful.

The next subject to which he had to allude was Mr. Hullett's "New Food." He had heard from Mr. Hullett, who thought it rather cruel of Mr. Bateman to say what he did at the last meeting, leading people to suppose that the seed he (Mr. Hullett) sent out was only Holcus saccharatus. He sent the black seed to no one except to show the difference between it and the true thing (Sorghum tartaricum), which has white seed, and this he sent to over ten thousand applicants; the residue had a variety with brown seed, which is even hardier than the white, and both were grown by him at Waterloo last year, and both were perfectly hardy, which the other (with black seed) was not. "So much for Mr. Hullett's statement," said Mr. Bateman; "now for my defence. In the only two collections (those sent to the Royal Horticultural Society and to myself) in which all the three varieties (white, brown, and black) were included, not a hint was given which was the true Simon Pure. I was, therefore, obliged to find that out for myself, and my only chance was to go to the seed-shops; and at half a dozen around Covent Garden I asked for the Chinese Sugar Grass, and in every case a packet of the black seed was handed to me." Mr. Bateman therefore concluded that the black seed was the right sort, instead of which the white or the brown ought to have been selected. So much for the colour question, now for the question of names. As Mr. Hullett spoke in his letter to the *Times* of the "Chinese Sugar Grass," after which in brackets followed the words Sorghum tartaricum, it was natural to infer, according to botanical usage, that the Chinese Sugar Grass was Sorghum tartaricum and Sorghum tartaricum the Chinese Sugar Grass; but the Chinese Sugar Grass, as such had always been understood in this country, Mr. Hullett's S. tartaricum certainly was not. What, then, was it? Whence did he get the name S. tartaricum? Who gave it the name? He (Mr. Bateman) had spent several hours on Monday at the Linnean Society's, and with the assistance of the Librarian (Mr. Kippist), had tried to discover some trace of S. tartaricum, but all to no purpose. Neither among the Holcuses, nor the Sorghums, nor the Andropogons, a genus in which the former are sometimes included, was there any tartaricum to be found, and if any Tartar was to be caught Mr. Hullett must catch him.

With regard to the Sorghum he (Mr. Bateman) had collected the following information. Mr. Fortune stated that at one time the French were very hopeful it might turn out a substitute for the Sugar Cane, and tried it extensively in the south of France, but it failed. It might be useful as a fodder for cattle, but it requires a climate like that of Teintsin or Pekin, and where Rice would not grow its place was taken by tall kinds of Sorghum, some as much as 12 or 15 feet high; and it was from the long stout stubble of this Grass that our cavalry horses in the late Chinese war suffered so severely. Mr. Thompson—that faithful veteran in the service of the Society and of horticulture—remembered it about a dozen years ago in the Society's garden, and about an acre of it was grown near Chiswick station by Mr. Jessop, and was cut for cattle in pieces a foot long. Mr. Bateman also quoted Dr. Roxburgh as to the uses the Holcus or Sorghum is put to, as well as Dr. Royle, who says that the different kinds of Sorghum (called durra by the natives), or Great or Indian Millet, are an important branch of Indian cultivation. The species most commonly grown were S. vulgare and S. bicolor; but in another list all were classed together—viz., S. album, rubens, nigrum, nigricans, and nigerrimum. He (Mr. Bateman) had also examined the specimens in the possession of the Linnean Society, arranged by Dr. Wallich, which formed part of the East Indian herbarium, and all were treated as varieties.

Mr. Bateman concluded by expressing a hope that Mr. Hullett would tell where Passiflora Hullettii (fruit of which had been pronounced superior to the Pine Apple), had fruited; where and when the Durion was fruited; where the Mangosteens and Mangos, which were cut in dozens and sold at 2*s.* 6*d.* a-piece, were produced.

Major Clarke remarked, that he had known Sorghum saccharatum grown as food for horses, and that there were several black-seeded Sorghums which were not S. saccharatum, one of which was grown in Italy as food for chickens.

Dr. Masters asked Major Clarke if he had succeeded in raising seeds from all three forms of Cytisus Adami. That plant and the Cyclamens and Apples at the meeting tended to shake our faith in the power of grafting to perpetuate any particular variety. This was a subject which well deserved fuller investigation than it had hitherto received.

Major Clarke said he had saved three packets of seeds from the three different forms of Cytisus, that he had sent them to Dr. Lindley, who had given them to Mr. Gordon, and that the seeds of the Cytisus Adami, or "hybrid portion," had produced yellow blossoms like the Laburnum.

Sir Philip Egerton invited Mr. Murray to make a few observations on the Coniferæ; and after Mr. Murray had noticed two or three specimens, the names of which were doubtful, Mr. Bateman announced that Dr. Masters would give five elementary lectures on Botany, beginning on the last Saturday in March.

THE INTENSE COLD AND ITS CONSEQUENCES.

Longmead, Hants.—The following is a list of a few trees and shrubs injured by the late severe frost here:—Pinus insignis, young plant, 6 feet high, young shoots killed; Garrya elliptica, killed down to the snow line. Escallonia macrantha bronzed, but the fresh leaves are beginning to show now; it was presented by the late Prince Consort when on a visit here. Azalea indica rubra, young wood killed, while Azalea indica alba standing 20 feet from rubra, was not in the least hurt. They are both by the side of an east walk. Bays and Laurustinus are very much cut up. All my Broccolis, with the exception of the Brimstone, are killed. Brussels Sprouts are not in the least hurt. I may remark that I have gathered this week, from a south wall, some Camellia blossoms, one bloom from Lady Hume's Blush, and three from a Double Red, and twenty will be fully open on the Double Red by the end of the month (February).—J. Sharp, *Gardener to A. Barton, Esq.*

Wilmont, Belfast.—Now that we can look around and see the effects of the unprecedented snowstorm of January, it will, perhaps, interest some of your readers to learn how we have fared on this side of the Irish Channel.

Roses appear to have suffered less here than in many other places, yet they have not come off quite safely. Lord Clyde, Mdlle. Bonnaire, and Monte Christo, are dead; Belle de Bordeaux, Triomphe de Rennes, and Celine Forestier are much injured; Duc de Cazes and Mrs. Chas. Wood are slightly injured. These were all worked on the Dog Rose stock. I have not a single instance of death or severe injury on the Manetti, and, hence, with Mr. Taylor, I am "all for Manetti." Of the buds inserted in the Dog Rose in the autumn, all which had pushed or were prominent have been killed. The common China Rose has been killed to the snow line.

Of evergreens—Laurustinus, Escallonia macrantha, hybrid scarlet Rhododendrons, and Arbutus unedo, have suffered severely. Portugal and common Laurel (particularly those recently transplanted), Sweet Bay, Golden and Silver Hollies, together with young plants of Pinus insignis, have been more or less punished. A plant of Desfontania spinosa is quite dead. In the immediate neighbourhood Araucaria imbricata and Cedrus deodara are extensively killed.

In the kitchen garden, Snow's and Hammond's Cape Broccoli were all killed; Knight's Protecting was much injured; Dalmeny Park proved hardier than any other Broccoli grown here; Savoys and Brussels Sprouts came well through; Globe Artichokes and Cabbages were very much injured; Endive, Lettuces, and White Lisbon Onion entirely escaped, as well as a sowing of Sangster's No. 1 Pea, which was fully an inch above the ground. Out of several sorts of Celery which were unprotected, Laing's Mammoth was the only one injured.—J. M. Bothwell.

GROUND VINERIES.

[From a paper read by Mr. Broome, of the Inner Temple Gardens, at the meeting of the Central Horticultural Society, February 26th.]

Now that the gardening world is every day becoming acquainted with the great utility of these structures, I have thought a few remarks, based upon practice with Wells's ground vineries, might by many be appreciated. The lady and gentleman amateur, the scientific and practical gardener, have already derived much advantage and pleasure from their use; and at this moment in many gardens where horticulture is carried out upon just principles, these structures are used and recommended. Upon their first appearance in gardens they were exclusively employed for Grape-growing, and were carefully stowed away during the many months in which the Vine is dormant; now they are kept in active operation during the whole year. The lady amateur finds that in them she can manage a crop of Grapes, then bring on a few plants for late autumn and Christmas flowering, and afterwards occupy them with a few miscellaneous floricultural pets, bedding, and other plants; whilst by others they are used for the protection of salading, &c. In the present month many ground vineries are devoted to forcing Rhubarb, and I have seen a hotbed made for them and covered an inch thick with ashes, into which are plunged pots of Dutch bulbs, Hyacinths, Tulips, &c.; and others, again, are used in a similar manner for the propagation of bedding stuff, and raising seeds of tender plants.

The scientific and practical gardener can apply these miniature houses to a thousand different uses. But a few days ago I saw a 14-feet length filled with Hyacinths and Tulips, which are intended for our great spring bulb shows, and nothing could exceed the luxuriance and vigour they possessed. I have likewise seen ground vineries applied to the growth of the Neapolitan Violet, and beautifully-coloured blossoms were being

gathered when not a vestige of flower was discernible in the old-fashioned, dark, dismal box-frame, although both were placed near each other, and were subjected to the same and equal management. The plan of arranging the ground vinery for this purpose was extremely simple. In the month of October last, when all the fruit had been cut from the Vines, a bed of the same area as the vinery was marked out, round which common bricks were laid two deep; the bed thus formed was filled with coal ashes, and the Violets, which had previously been potted in 32-sized pots, were plunged in it. The plants were thus exposed to intense light—an agent most essential, as all gardeners are aware, to the well-being of this plant. The arrangement for giving air is likewise so perfect in these structures that the Violets can be exposed wholly in propitious weather, and should it be mild with moisture falling the lids or sides can be raised nearly horizontally, thus exposing the plants to air, whilst affording protection from wet. During the inclement weather we had this winter the vinery was covered with litter, and thatched hurdles placed together over the whole in the shape of a span roof. This protection bade defiance to cold 9° below zero.

During the past season I have seen some magnificent crops of Grapes under these ground vineries. The bunches were of a good size, the berries well swelled and above the average size, with the colouring as perfect as in any that have been cut from more spacious houses, and the flavour was exquisite.

I find many growers, elated with the success of these vineries, intend applying them to the growing of stone fruits, such as Peaches and Nectarines, the trees being planted out and treated precisely the same as the Vines. The slates will be laid down and perforated at regular distances, so as to admit pegs for the purpose of pegging down and laying out the branches. The roots being free to act on the outside, as in the case of Vines, no watering is necessary, as when these fruits are grown in pots upon the orchard-house principle; and the moisture evaporated from the slates, with which the wood and foliage are in contact, prevents red spider, thrips, and other insects from multiplying.

I find the best method of cultivating fruits under Wells's ground vineries is as follows:—At one end of the vinery a hole, 2 feet square, and of about the same depth, is dug out and filled with a compost of good loam, rotten dung, and a little road sand; these should be well incorporated together, previously throwing in about one and a half peck of bones, merely bruised, to afford drainage to the mass, also to feed the Vines during hot weather, or when the heat is so great as to rob the plant of its natural moisture. The bones will likewise absorb the fluids passing down to them more readily by being bruised. All being thus prepared, the Vine is turned out about the middle of March, providing the weather is open and mild, the cane being introduced and pegged down. Air should be admitted at ten o'clock, A.M., by raising slightly the lights; this, with the additional air from the bottom of the frames, will serve to check the Vines from making too quick and premature a growth before the season is sufficiently advanced to assist the formation of the young parts. The cases should be closed again about 2 P.M., if possible securing a little atmospheric warmth, and the Vines should at this period be slightly syringed; the moisture will aid the expansion of the bark and the bursting of the young buds and leaves. This treatment should be continued until the flowers are expanded, when syringing must be entirely suspended and air admitted upon every opportunity. As soon as the flowers are set I find moisture applied in the form of vapour highly beneficial; this can be obtained by pouring tepid water upon the slates. Atmospheric warmth is secured throughout the day, and causes the moisture to evaporate, thus charging the internal air with an agent highly beneficial. As soon as the Grapes have attained the size of Sweet Peas the bunches should be thinned, taking out all ill-shaped and deformed berries, also all those which are in immediate contact with others, taking care not to remove all the interior berries, or the bunches will be loose and ill-shapen. At this period the structure should be kept close and as much warmth secured as possible, as the critical time of stoning will have arrived, and a check would prove highly injurious. As soon as colouring commences as much air should be admitted as is consistent with safety from chilling, and the vinery should be closed sufficiently early to secure, as before stated, as much natural warmth as possible. If this course be pursued I feel confident every success will attend the operator, and will well repay him for the pains he may bestow; the weight and quality of the fruit will equal if not exceed that which is grown in extensive Vine-houses.

I have this winter seen a very happy adaptation of the ground vinery. One of the 14-feet vineries was selected, a site facing south was arranged, a pit dug 3 feet deep, and the sides bricked with 4½-inch work 2 feet above the ground level; upon the brickwork was laid a wooden plate, and to this the vinery was fixed, being screwed down at the four corners of each division. The pit was then filled with cocoa-nut fibre, and such plants as Fuchsias, Pelargoniums, and bulbs were placed in it. These grew with great luxuriance, and, as in other cases where they were well covered with litter and the thatched hurdles, resisted the intense frosts we experienced in January. The same vinery-pit is at this moment filled with fermenting material, and Rhubarb, Sea-kale, and salading are being cut, while there are Cucumbers climbing along the roof and looking as luxuriant as upon ridges in summer. Dutch bulbs are also being brought out weekly for the drawing-room. This plan is merely an enlarged idea of what was before exemplified, and serves to prove how valuable ground vineries are to the horticulturist.

HARDINESS OF TRITELEIA UNIFLORA.

WILL you tell me whether Triteleia uniflora will stand the winter in the open ground? Having it now in bloom in pots—and it is a lovely flower—I feel anxious to know whether it is hardy. Should it be so, it will be an acquisition to our spring bulbs, and ought to be largely grown. In my opinion it is most beautiful.—M. H., *Acklam Hall, Middlesborough-on-Tees.*

[We believe it to be hardy; and should have no hesitation in leaving it in the border throughout the winter, with no other covering than an inch or two of cocoa-nut fibre refuse or coal ashes. Some years since a gentleman wrote to us thus:—"There is one plant I would particularly call your attention to—the Triteleia uniflora. It is a bulb, and described as half-hardy, and blooming in June. With me (on the Mendip Hills), it thrives in a border under a west wall, without the slightest protection, and blossoms from the third week in March to the end of May. I think no flower is more delicately beautiful, and I wonder that it is not as common as the Narcissus."]

ENTOMOLOGICAL SOCIETY.

THE second meeting in February was held on the 18th inst. at Burlington House, the President, Sir John Lubbock, Bart., F.R.S., &c., in the chair. Amongst the donations to the library received since the preceding meeting were the publications of the Imperial Society of Moscow, the Entomological and other Societies of France, Stettin, Dublin, and Christiana.

Mr. Frederick Moore exhibited a number of specimens of a minute wood-boring Beetle, Tomicus monographus, a species not hitherto detected in England, which had proved very injurious to the oaken staves of casks of malt liquors in India, causing in some instances the loss of the liquor to the extent of 50 per cent. The injury had been first noticed in Burmah, and the casks when first landed from the ships did not appear to be at all injured. As many as 1,340,000 perforations had been observed in the staves of a single cask. It was suggested that either the steaming process to which the staves are subjected to bring them into shape, or the taste given to them by the liquor, had rendered them palatable to the insects, which appear to be nearly allied to the Bamboo-borer.

Mr. Newman exhibited the lock of a garden gate completely filled with the mud nests of a wild Bee, Osmia bicornis; some portions of the stem of Sallow, Salix caprea, burrowed into by the larvæ of the Hornet Moth, Sesia bombyciformis; also some large Ants, Formica herculanea or pubescens, said to have been taken at Kinloch Rannoch, in Perthshire, each having made a cell for itself in rotten Oak; and a specimen of Lithosia ancella from Worthing.

Mr. F. Smith exhibited two boxes filled with Hymenopterous insects of great interest, collected at Champion Bay on the north-west coast of New Holland by Mr. De Boulay, including a number of new species of Formicidæ, Mutillidæ, Thynnidæ, and Apidæ.

Mr. Stainton exhibited two species of Microlepidoptera, Zelleria oleastrella and Margarodes unionalis, reared from the Olives at Mentone.

Professor Westwood mentioned that a specimen of Vanessa urticæ had been captured on the 7th inst. at Oxford by Dr. Rolleston, which proved to be a male, and on dissection its abdomen was found to be filled with oleaginous fluid.

Mr. R. A. Wallace read an elaborate memoir on the Pierideous Butterflies of the Malayan Archipelago, in the introduction to which he entered into numerous details as to the geographical range, affinities, and mimetic analogies of the different groups; which led to an extended discussion, in which Mr. Pascoe especially maintained the distinction between the Faunas of the eastern portion of the Archi-

pelago and New Holland, which had been considered by Mr. Wallace as identical.

A very elaborate memoir on the distribution of the species of Lepidoptera in Great Britain and Ireland, on the plan of Mr. Hewitt C. Watson's "Cybele Britannica," by Mr. Herbert Jenner Fust, was read; as well as a paper by Mr. E. Saunders, containing descriptions of new species of Buprestidæ, collected in Penang by Mr. Lamb.

NOTES AND GLEANINGS.

The Duke of Buccleuch, President of the Royal Horticultural Society, has nominated the following gentlemen Vice-Presidents for this year:—Lord Henry Gordon Lennox, M.P.; Mr. James Bateman, F.R.S.; Mr. Henry Cole, C.B.; Mr. W. Wilson Saunders, F.R.S.

—— When announcing the death of Mr. Skinner, we commented on his befriending Joseph Ritter Von Rawicz Warscewicz, and now we have to record that this botanist's death preceded Mr. Skinner's eleven days. He was Inspector of the Imperial Botanic Garden at Cracow, and was only in his fifty-fourth year. He died at Cracow on the 29th of December.

—— The Members of the Royal Horticultural Society will be glad to learn that, as announced in a report in another column, Dr. Maxwell T. Masters has kindly consented to give five elementary lectures on Botany, illustrated by diagrams and living specimens, in the Council-room of the Society, commencing on the last Saturday in March.

WORK FOR THE WEEK.

KITCHEN GARDEN.

If the weather is favourable make sowings forthwith, on well-situated beds of the following vegetables—namely, *Brussels Sprouts*, *Chou de Milan* (Thousand-headed Cabbage), *Cauliflower*, Dwarf *Cabbage*, *Green Kale*, *Savoys*, and *Leeks*, also a little Pomeranian Cabbage, and a sprinkling of some late spring *Broccoli*. Give a slight salting to all *Asparagus*-beds and *Sea-kale* ground. Sow *Peas*, *Beans*, and *Radishes* as soon as the former sowing is above ground. Prick-out very early *Celery* in a frame. Old mellow dung made firm is good, and prevents tap roots. Sow all herbs, *Sweet Marjoram* and *Sweet Basil* on heat. Cover up with litter all early slopes of Radishes, Horn Carrots, &c., whilst the sun shines, about three o'clock, and water them about once a-week with tepid clear manure water.

FRUIT GARDEN.

Protect by all possible means the blossoms of fruit trees. Straw ropes, mats, canvas bunting, Fir boughs, and fronds of Fern, should all or any of them be in requisition. As soon as you have finished nailing the Peach trees, mix sulphur and soft soap water to the thickness of paint, and draw a band of the mixture between the shoots in all directions; this once done, and that well, will secure the trees thoroughly from red spider for a twelvemonth. Throw soot over Strawberry plantations requiring manure. Now is the time for grafting, and for various reasons the mode called whip-grafting is by far the preferable one; in cleft-grafting the divided portions of old wood never re-unite; in saddle-grafting the flow of sap is limited to two tapering strips of alburnum; and rind-grafting leaves cavities on each side of the inserted portion of the scion. In grafting it should be remembered that sections of wood already formed never unite; they are seen, if divested of all subsequent formations, in mere mechanical contact after a lapse of many years, and the scion and stock will then readily fall asunder, nor do the outer barks form a vital union; but when newly-formed tissues of both stock and scion come in contact, they coalesce, and an organised growth immediately takes place. This organisable tissue protrudes from between the wood and inner bark; the inner barks of the scion and stock should therefore be made to coincide as far as possible, and without the least regard being paid to the positions of the outer barks, the nicely fitting of which is unnecessary.

GREENHOUSE AND CONSERVATORY.

Potting will now be a matter of daily occurrence, and on the mode in which this is performed will depend the future success of the plant. We need say little here about the propriety of using fibrous loam or about thorough drainage, their importance is now tolerably well understood; but a few words to the amateur may be acceptable as to the best mode of watering newly planted subjects in general. Let it be a maxim, then, never to water a fresh-potted plant until it is fixed where it is to remain. I have known persons give their fresh-potted plants a thorough watering whilst on the handbarrow to "settle the soil," as it is termed, and then immediately carry them to their destination. This, although called gardening, should be termed "puddling;" it is not possible for plants to thrive after such handling. The soil for potting should be neither wet nor dry; one is as great an evil as the other; it should of the two incline to dryness, and should be pressed tolerably firm, not thumping the pot on the potting-board. The watering at first should not be performed in order to settle the soil, this means shutting out the atmosphere, but merely with the intention of preventing the soil from becoming any drier. Hard balls should be soaked overhead in water a day previous to shifting. The families of Camellia, Acacia, Cytisus, Phajus, Rhododendron, Eutaxia, Citrus, Epacris, Correa, Azalea, and last, but not least, the Rose, will be a blaze of beauty in the conservatory where plant-growing is well attended to. They will now require abundance of water, to which clear liquid manure should occasionally be added. Dispense with fire heat as much as possible; the enormous perspiration caused by a March sun is more than enough for some of the evanescent beauties without the aid of fires. Canvas screens, too, should be at hand to be drawn over the brightest parts of the house for two hours in sunny days. Force on Fuchsias where fine and large specimens are required; a moist atmosphere, with a slight degree of shading, will run the shy sorts into wood by retarding flowering. Those wintered under stages or in cellars should now be brought forth and potted, to give them a start for the decoration of lawns or the flower garden. Brugmansias should be disrooted and started in heat. Shift, when necessary, Australian and Cape plants in a growing state, likewise Pelargoniums, Calceolarias, and Cinerarias, with the view of having fine specimens. Pot successions of Gloxinias and Achimenes, and keep them rather dry and warm.

STOVE.

Orchids are now swelling fast, and many of the blocks and baskets of Stanhopeas, Gongoras, Dendrobiums, &c., will require to be syringed about twice a-week; let it be done on sunny mornings early, and give air freely for a couple of hours for fear of moisture lodging amongst the buds. In shifting large specimens in pots break the pot carefully all round so as to avoid injuring the roots, and shift the whole mass together. Terrestrial Orchids, in general, do better in loamy turf and leaf mould (not too much decayed), blended with the lumps of peat. Renew moss on blocks forthwith. Attend to disrooting and pruning back Justicias, Vincas, Clerodendrons, Eranthemums, Geissomerias, Plumbagos, Poinsettias, Erythrinas, &c., at least those exhausted by flowering, and a few for early work. Those done first, if carried on in due course, will be the earliest next autumn and winter.

FORCING-PIT.

Keep Roses free from insects, watering frequently with liquid manure. Provide successions of subjects for forcing. The Dutch bulbs should not stay long here. The Hyacinths lose much effect when their bells are too much asunder through too much excitement in proportion to the light. Sow tender annuals. Do not forget Phlox Drummondi and Rhodanthe Manglesii, with the Portulacas.

PITS AND FRAMES.

Pot-off Lobelias, and place them in a growing heat; the compost should be light and rich for the first potting. Sow Stocks and other choice annuals, and pot-off all kinds of cuttings as soon as they are ready, filling up the pots again with sorts that are wanted. As soon as the borders are in a proper state sow hardy annuals in patches, and not too deeply—a slight covering for the seeds will be sufficient. Mark the places with small sticks, or make a small ring, which will prevent any other thing being planted over them. Prick-off Clintonias, Portulacas, or other choice and tender annuals that are fit for the operation, and keep them in gentle heat until they are rooted, then remove them to a colder temperature, except the most tender kinds, which should be nursed until milder weather. Air the cold pits continually at night as well as by day, if there be no frost. Pot-off stores for the flower garden, and forward them, more especially scarlet Pelargoniums, Salvia patens, and Verbenas. A good collection of the best hardy annuals should now be sown, they are of most service and most esteemed before the gay masses of Verbenas, Pelargoniums, &c., come to perfection. When a frame or a pit is at liberty I would recommend their being sown in small pots in loamy soil, and not turned out until they are slightly pot-bound; the flower then gains the predominance, and the great proportion

of this above the leaf constitutes the chief beauty of many of the annuals. They are also more easily protected from slugs.—W. KEANE.

DOINGS OF THE LAST WEEK.

KITCHEN GARDEN.

So far as frosty mornings are concerned, March has "come in as a lion," and it remains to be proved whether it will "go out as a lamb." The frost will do good in three ways—it will help to keep back fruit-tree blossoms, the buds of which were becoming too forward for the season; it will dry and crumble down the soil thrown up in ridges; and the sun, which has followed the frosty mornings, will help all plants that were languishing in the dull weather, and will be of especial benefit to plants in bloom that are intended to bear serviceable fruit. With the exception of planting some Potatoes at the bases of walls, planting-out more Cabbages, hoeing and forking the ground among Spinach, so as to let the air circulate about the plants, and partially dry the over-wet soil, the chief work out of doors has been turning over the ridged ground, and leaving it in shallow ridges so as to have it better exposed to the air and dried before sowing and planting general crops. Much of this labour would be worse than unnecessary in open light soils. In such cases even ridging is often better dispensed with, as, provided the staple has been sufficiently stirred, the crops do better when the light soil is compressed rather than loosened. A heavy soil requires to be made lighter even for *Onions*, provided the surface is rolled when dry with a light roller, or gently patted; and in many cases it is better to dispense with both of these operations, and leave the surface for a quarter of an inch or so loose or open, to prevent the stiff soil cracking in dry weather in all directions, even before the seedlings are large enough to permit of hoeing on the surface to leave it loose. In light soils, even with heavy manuring, a good crop of firm, fair-sized Onions can scarcely be secured without consolidating the surface. Under such circumstances, when the ground was too wet to roll at the sowing time, we have frequently rolled with a light roller when the seedlings were just appearing, or not more than an inch in height, and then if there was the least danger of cracking, a stirring with a hoe, as shallow as possible, between the rows would leave the young Onions firm enough at the surface, and thus tempt them to quick bulbing instead of forming huge thick necks. For all such crops, however, we would sooner wait a week or ten days at this season than sow when the ground was in an unkindly state. Further on in the season sowing must often be resorted to, even if barrowloads of material should be brought for covering. What collects about the potting-bench when riddled is generally very useful for this purpose.

Turnips.—It is too soon to sow yet out of doors unless the young plants are protected from frost, and where deemed of much importance young Turnips would pay as well under glass as young Potatoes. It is not because of their tenderness that it is too soon in most places to sow them out of doors, but because of the simple fact, that when young plants are touched with a few degrees of frost they are almost sure to throw up flower-stems, and if a small Turnip is then formed it is little better than a piece of soft wood. In cold places, when wanted early out of doors, the young plants will need protection in cold nights.

Partly owing to the rains and warmth of autumn, a young crop with bulbs the size of hens' eggs, on the north side of a sloping bank, is already showing flower-stems, and though these may be cut off, others will come, and the Turnips will soon become hard in consequence, so these young plants will not be so useful as we expected, and as we have found them in most years. Those we spoke of lately as pulled up before showing any signs of fresh growth, and which had suffered nothing from the frost at the new year, have shown signs also of growing, and have, therefore, had the tops cut and have been laid in thin layers in a cool shady place, with just a sprinkling of litter over them to preserve them from extremes of weather. These will remain good for use when those on the bank, though much younger, will be too stringy and hard.

The chief work in this department has been keeping up a succession of forced vegetables, Sea-kale, Mushrooms, Rhubarb, Radishes, &c.; forwarding Peas and Beans, and carrying on a ceaseless warfare with our vermin enemies.

In the *Mushroom-house* the fourth piece was finally earthed down in the usual way—that is, covered with rough turfy loam to the depth of about 1½ inch, well beaten, and from a quarter to half an inch of finer soil added, beaten firm, watered gently, allowed to settle a little, and a clean spade drawn firmly over it, so as to leave a smooth surface. This, when a little dry on the surface, is covered with just a sprinkling of hay, which keeps the casing from cracking, and renders the bed more uniform in heat and moisture. In a Mushroom-house that is heated by flues or hot water this hay covering is not essential. We very often use it, however, as we can regulate the state of the bed more easily by its means; and hence, though we have used light soil for earthing over very successfully, we prefer it rather stiff, fresh, and beaten firmly to a smooth surface, so that when we like we can sweep the surface of the bed clean, and thus the spawn is prevented running on the bed instead of sending up plenty of Mushrooms. In a fresh bed, watered and made solid on the surface, the first sprinkling of hay will soon become wet; as the bed dries that will be removed once or twice, and fresh added before the Mushrooms show freely. If they come faster than is wanted, the hay or litter covering is removed. If they are wanted quicker, more is added. If the bed has produced all over at once, and yielded a heavy gathering, then often we sweep the bed clean with a hair broom, water if dry, cover with a couple of inches of rough hay, and in a week or two the bed will be like a sheet with white Mushrooms. Although not always the case, it very generally happens that the Mushrooms thus covered are whiter, and those more exposed come browner in the skin. Another advantage of this hay covering is, that when successional beds are used, the heat they throw off before being ready for spawning will generally be enough for the house without fire heat. We have seldom used the hot-water pipe this season, except during the severe frost in January. From 50° to 55° is high enough for the atmosphere for bearing beds in a house. The advantage of dispensing with hay and using a regular fire heat, is that you see all the beds at once, and there is less refuge for woodlice, &c.; but as it is, we seldom see any woodlice until spring, and then we have beds under the thatched, covered shed open in front. In that shed are good Mushrooms still, but with 8 or 10 inches of litter over them. The fifth piece in the Mushroom-house has had the last layer of dung put on, the dung mixed with turfy loam, and in a week or ten days it will be fit for spawning. The two first pieces are bearing well, the third will show before long. This succession of shallow beds, though entailing a considerable amount of attention, generally secures a good regular supply. Our most celebrated artistes of the kitchen tell us that two things are indispensable to good cookery—Mushrooms and Onions.

Sea-kale.—One of our best gardeners told us the other day that he followed the same plan in winter as we do—namely, took up the roots and packed them in pots, only we put ours in the Mushroom-house, where it is dark enough to cause the Sea-kale to come quite white, and he puts his in any place—a house where there is heat, a stokehole, &c., and covers securely with another pot so as to keep out the light. In one point we differ: he sows every year, so as always to have a succession, and after forcing he throws the old plants away. We plant ours out again, taking them out of doors first and covering with litter, so that they may not be injured by a sudden change of weather. We like young plants very well, but these forced plants so treated we consider quite as good as seedlings of the second year. We mention this all the more, as many in small places may find a little difficulty with seedlings, as, when in the seed leaf, they are subject to insect enemies, and before they attain that size they must be protected in the ground from birds, mice, &c. Plants taken up and forced this winter will, under ordinary treatment, when planted out be first-rate for forcing again in the second winter—that is, after having had two summers' growth. If in the summer the crowns show too many shoots or buds it is well to thin them to two or three. Just as in other cases, if two, three, or more crops are taken from forced plants, they will in proportion be less useful when planted out; but in almost every case, if treated as stated above, they will be as useful for transplanting as one-year seedlings that were sown rather thickly.

Rhubarb.—Similar remarks will apply. We have just turned out some of the roots forced, planted them again, and covered with a little litter. They will not do much the first summer, but they will come strong in the second, and in the following winter will do for forcing again. Good gatherings may be obtained in spring from seed sown in April twelve months before; but to have strong stalks in winter the seedlings should have two summers' growth. We will put a few more lumps into the

Mushroom-house; after that the most forward out of doors, we hope will come in with a little protection. Sea-kale out of doors, we hope, will come in a month or six weeks hence, with merely a box or a pot put over it to keep out the light.

Potatoes.—We did not plant the long earth pit with Potatoes, as alluded to the other week, for the Potatoes were not over-forward, and whilst they remained where they were we would save some covering in these frosty nights; but we must not delay longer than Tuesday or Wednesday. We find those growing in pots must be moved to afford them more room, as crowding early Potatoes is. like all crowding, anything but true economy. Our friend, alluded to above in reference to Sea-kale, gave us a very good idea, which might be often usefully adopted in small gardens where successional cropping must be generally followed. We were discussing the properties of varieties of Potatoes which produced the smallest tops, so as to permit of cropping between the rows, as the various Ash-leaved Kidneys, Handsworth, Frames, Early May, Coldstream, &c. To surmount the difficulty our friend generally plants his early Potatoes thus:—Two rows are planted 18 inches from row to row; 30 inches are left between these and the next two rows, and so on through the space to be planted. In the centre of the 30-inch space he plants in summer permanent strong-growing winter stuff, each row of which will thus be 4 feet from the other. If the Potatoes threaten to encroach, the heads of the two rows are turned towards the 18-inch space without injuring them. Thus the Potatoes are not injured by planting between the rows, the permanent winter crops do not suffer in digging up the Potatoes, and when these are dug up and the ground cleared, lower-growing crops may be planted where they stood. If the Potatoes had large heads the space between every two rows might be a few inches more, and then the interval left might be 3 feet instead of 30 inches. We have much practised this successional cropping by planting between every two rows, but often we would have preferred to have let the crop of Potatoes alone until it was taken up, and have had good strong plants previously pricked out and well rooted to lift again, and such often did best and presented the most regular plantation. We have not for years practised our friend's plan with Potatoes and Winter Greens, but we have no doubt it is well worthy of adoption, as saving so much pricking-out and relifting, and ensuring room for the plants when first turned out, without the liability of their being injured when the crop of Potatoes is taken up.

Vermin.—We are afraid to say how many beautiful tomtits and blackcaps are hanging on the branches of a tree. We are sorry to look at them, for we know the value of tomtits in summer; but it is a clear case, that if they are allowed to have their own way now there will be neither Pear nor Plum for them to dab their little bills into next autumn. We know of no other remedy at this season than close netting. Then there were rats and mice to be thinned and driven away. Will some naturalist tell us if there is war, or at least a feeling of repugnance between the two races, rats and mice? At any rate, we have frequently found that when we had almost freed ourselves of one kind, we soon had plenty of the other, though at times we have had more than enough of both. Frames over dung-beds are dear places to both, and tarring the bottoms of frames outside, allowing the tar to drop on the dung there, is a good way of keeping them away, so long as the tar continues moist and smells strong. Rats for some time were in great force, and trapping half a hundred seemed to decrease their numbers but little; so, having a fortnight ago caught a fine fellow in a trap, we were cruel enough to singe his hair, paint him a little with tar, and let him free again. Since then we have not noticed a single rat. In a few days, however, we had an invasion of mice, three or four varieties; we trapped many, but still they come, and in one night they ate out the hearts of half a dozen Strawberry plants in pots, nibbled Asparagus, cut over Radishes, and cropped over a nice bed of young Carrots, so that, much against our will, we have been forced to resort to poisoning as well as trapping. The varieties of the grass mice, especially, are particularly partial to Strawberry plants in pots just when the centre begins to rise. We used to protect plants in pots in earth-pits in winter, leaving litter over them in severe frost; but we are afraid to trust them out of sight now. We had two plants sent lately with inquiries as to why they would not flower, there being many more like them. The centre had been eaten out neatly by mice. If the plants stand plunged in an open bed mice will rarely touch them; but set them in a frame, or cover them up in a pit, and the mice will soon begin to taste them. Strange that mice, like men, should relish most that which is forbidden and most difficult to obtain.

FRUIT DEPARTMENT.

Much the same as last week as respects general work. Cleared out the litter that protected fruit trees in pots in the orchard-house, fresh regulated, fresh surfaced, &c., to give a neat clean appearance; but some matters here we must defer, and also in other departments, until next week.

Strawberries.—Took out Strawberry plants that had done their work, and replaced them with others, forwarded, as alluded to above, in frames, where a mild gentle heat had been given them. During the earliest stages of forcing, and especially at an early period, it is of importance that mere growth of foliage should not be greatly encouraged until the flower-trusses make their appearance. The most of the Strawberry plants lately moved into houses and pits, were brought from frames where there was just the slightest heat below them, so that the heat was given gradually—a matter of importance when successions are taken into houses. The beds were formed below the frames, chiefly of the clearings from the flower-beds and pleasure grounds, with a few inches of tree leaves above them firmly trodden, and then sprinkled with coal ashes, and on these beds the plants were placed without plunging the pots, as we have long proved that plunging pots full of roots in a bed where there is much heat, before March or April, has a tendency to cause the roots to find their way out at the bottom, and thus encourage a free growth of leaves instead of the free rise of the flower-truss. A correspondent highly satisfied with the vigorous look of his plants tells us, "On the 1st of January I filled a pit with Strawberry plants, plunged the pots in a bed, the heat at the bottom of the pots averaging 85°, and the top heat ranging from 58° to 65° at night; the roots are striking into the bed, and though the plants are seldom watered, the leaves are so green, and fresh, and large, that I cannot but think giving heat thus at once will far excel the jog-trot, gradual, bit-by-bit-addition system you are always recommending. Why not have a trial of a more quick slap-dash way?" Ah, why not? What of the crowns of the plants and the flower-trusses amid all this dash and vigour? We should not be greatly surprised if the fine leaves have taken all the running, and that in many cases the flower-trusses will never appear. Unfortunately fine foliage is not what is most wanted at the dessert table.—R. F.

COVENT GARDEN MARKET.—March 6.

The cool weather has somewhat diminished the supply of out-door vegetables, but prices remain nearly as last week. Asparagus is the only article a little dearer. The Potato trade remains heavy; prices are a trifle lower.

TRADE CATALOGUE RECEIVED.

William Hooper, St. John's Hill, New Wandsworth, London, S.W.—*Catalogue of Vegetable and Flower Seeds.*

TO CORRESPONDENTS.

*** We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed *solely* to *The Editors of the Journal of Horticulture, &c.*, 171, *Fleet Street, London, E.C.*

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

N.B.—Many questions must remain unanswered until next week.

Books (*S. B. C. V.*).—For the lad you mention no books would be more suitable than "The Garden Manual," "In-door Gardening," and "Out-door Gardening." You can have the whole free by post from our office if you enclose sixty postage stamps with your direction. (*A Lover of Nature*).—Whoever told you that a knowledge of botany would prevent your becoming a good gardener advised you ignorantly. Books to suit you are "Henfrey's Elementary Course of Botany," published by Van Voorst, price about 8*s.* we believe. "British Ferns" you can have from our office free by post if you enclose forty-six postage stamps with your address.

Overhanging Trees (*Neighbour*).—As no notice is taken of your request to have the branches of the worthless trees removed, let your solicitor write to the proprietor, and warn him that unless the lopping, &c., is done forthwith you will sue him for damages in the County Court

Variegated Lilies of the Valley (*S. S.*).—Those you allude to were exhibited by Mr. Salter, Versailles Nursery, William Street, Hammersmith.

Green Turf for Camellias.—"In reply to 'H. E.,' he will observe in reading my article that in potting my Camellias I finish off with a surface of half an inch of finely sifted loam. I find this a sufficient check for the weeds, but if any should appear 'H. E.' will find that one weeding will be sufficient.—Robert Fleming."

Hays's Patent Constant Stove (*E.*).—We think that you must not have employed properly prepared charcoal. We have one in an entrance hall, and have no tube. There is a slight smoke when first lighted, and a smell of burnt peat throughout the day, but we do not object to the smell. If we did we should have a small tube from the valve into a chimney or the outside air. The great drawback to this stove at present is the difficulty of obtaining a supply of good peat charcoal. We are informed the demand has exceeded the means of supply, and will be remedied.

Various (*C*).—Messrs. Byvoet, Overveen, Haarlem, and E. H. Krelage and Son, Haarlem, are very extensive dealers in bulbs. Any florist could supply you with Campanula pyramidalis to flower this year. No one could state marks whereby to distinguish Hyacinths of the same colour and form which have been mixed.

Potatoes (*Grammars*). — You can procure your namesake Potatoes from Mr. Frederick Gill, Dorset Nurseries, Blandford. He can also supply two other excellent Potatoes—Red Robins, great croppers, round, and rich; and Salmon Kidneys, which I am now eating—they are excellent. These and Grammars are always good up to digging time. Addison says, "No one is ever thanked for advice." I will, however, advise "Grammars" to purchase all three. The best novelty in every respect is the reniform Yorkshire Hero, derived from the Lapstone and Ashleaf. It is second early, a great cropper, very hardy against spring frost, and as good as the Ashleaf. I have had it three seasons.—W. F. Radclyffe.

Peat Charcoal (*T. M.*).—Our correspondent wishes to know how to make peat charcoal. "T. M." has made a trial, but with a waste of four-fifths of the peat. It is so tenacious of combustion when once ignited that "T. M." found nearly all of it consumed before being thoroughly charred. Should it be dried before being charred? "T. M." tried it just as taken out of the ground and very wet.

Roses in a Greenhouse—Planting Flower-beds (*A. B. A.*).—1, You should prune the Tea Roses in the greenhouse at once. We would, as you propose, cut all weak shoots back to one bud, but on stronger shoots leave two or three buds. You will need little more insight into pruning Roses than this, that if you leave only a few buds you may expect each bud to furnish a shoot that will bear Roses. It is often better, therefore, to cut out weak growth and leave more than one bud on a good shoot. 2, Verbenas would do very well for your round bed, filled with yellow and blue Crocus. Both will do better if the Crocuses are in rows or bands, so that the Verbenas can be planted in the intermediate spaces and a little rotten dung forked in before planting. 3, We suspect your variegated Alyssum is the Variegated Arabis, as the former is not hardy. We do not plant groups, or we might do nothing else, but we criticise proposed planting. Your group would look very well if your central star-like figure were filled in the centre with pink, and the four wings with purple, edged all round with Alyssum. Then 5, 6, 7, 8 might be two scarlet beds and two yellow ones, the first edged with Cerastium, the second with blue Lobelia. 1, 2, 3, may be planted in bands of colours.

Encouraging Field Mushrooms (*T. S.*).—You do not say whether your field in which you wish to encourage Mushrooms is in tilth or in grass. If in grass your chances are most favourable, and in that case towards the middle or end of April and the beginning of May we would advise inserting pieces of spawn the size of a hen's egg, say 2 feet apart, lifting the turf to the depth of 1 inch or 1½ inch so as to insert it. The process would be quite as successful if you were to put a small quantity of fresh fibrous soil below the spawn, replace the turf, and beat it down. This will cause the spawned pieces to be a little higher than the surrounding grass, and so far save the spawn from being over-watered. When you gather the Mushrooms throw the bottoms and stalks about the field.

Hotbed of Fermenting Material (*Inquirer*).—In Vol. X., page 277, there are directions for managing such a hotbed, and any one by attending to these directions must be successful. However, we will publish a few more details probably next week.

Cucumbers (*J. Batty*).—Sion House Improved is a smooth-fruited variety. Kelway's Perfection is black-spined.

Muscat Grapes Spotting and Shanking (*T. Wilson*).—We have no doubt that in your case lifting the roots of the Muscat Vine would effect the desired cure, and we should prefer doing so to planting a young Vine, though the last mode would involve least trouble. In lifting begin at the extremity of the border by means of a deep trench, and work and pick away the soil, saving the fibres, and tying them in mats or cloths as you proceed. Then add at least a portion of fresh soil, fresh plant within 9 inches and 6 inches of the surface, and give a coating of 15 inches of warm litter to set the roots going. If in tracing out the roots there would be danger of injuring much the neighbouring Vines, then we would cut out the Muscat Vine, add fresh soil, and plant a stout young Vine, but if there is no such danger the older plant will be the better in every way.

Glass for South Conservatory (*T. H.*). — Hartley's patent, any rough glass, or coloured ribbed glass, will answer your purpose well. We have seen glass tinted green answer admirably. There will be plenty of light for the plants, and you will require no shading.

Netting for Protecting Peach Tree Blossom (*A Lady Gardener*).—The netting sent for our inspection, and to which you allude, was that kind known as hexagon netting, which you will find advertised in our columns. It is a very good protection, but to keep off severe frosts it requires to be doubled. Woollen netting, with quarter-of-an-inch meshes, is good. The netting should be removed daily during mild weather after the flowers open, but it may remain on during cold, frosty, damp days. A board 6 or 7 inches wide would be useful to fasten the netting to. The board will do if 2 or 3 inches wide, and in that case be equal to a coping.

Cucumbers Stopping for Trellis (*W. B.*).—Stop the plants at the second rough leaf by taking out the point of the shoot with the end of a sharp knife, and, making choice of the best of the shoots resulting from the stopping, train it to the trellis, cutting the other away. Take out the point of the shoot at 1 foot from the top of the trellis. For three lights you will require three plants, or if the house or trellis is more than 6 feet wide, a plant at every 2 feet along the front of the trellis. "Thompson's Gardener's Assistant" is one of the best of works on practical gardening. You will obtain the whole of the book in twelve parts at 2*s.* 6*d.* each, or in one volume 31*s.* 6*d.*

Cocoa-nut Refuse with Soil for Cucumbers (*Tyro*).—Cocoa-nut refuse will answer well for mixing with your soil for Cucumbers, if used in the proportion of one-third to two-thirds of your black garden mould. The time you name will answer well for making the bed.

Treatment of Old Bedding Pelargoniums (*Excelsior*).—You would be doing well to shake out the plants from the large pots they are now in, and pot them in fresh soil; turfy loam two-thirds, and one-third leaf mould, being a good compost. Keep the plants rather dry, yet moist, until the roots are working in the fresh soil, then water more freely. Afford the plants a light and airy situation, shift into larger pots in about six weeks after shaking them out of the soil, and in May remove them to a frame or pit.

Mrs. Pollock Pelargonium Culture (*Idem*).—The plants should now be shifted from 48's into 32-sized pots, using a compost of turfy loam two-thirds, and one-third well-rotted hotbed manure. They should be carefully watered, have a light and airy situation, and when the pots become full of roots must be shifted into 18-sized pots. Avoid copious waterings, and afford a position near the glass with a fair amount of air. Over-potting and over-watering are very injurious.

Grapes Rusted (*Charles*).—Grapes are apt to have a brownish skin round them if subjected to a sudden check from a great change of temperature, or if sulphur has been used freely on a heating medium when the berries are young and tender. Under such circumstances it is best to apply the sulphur during the day, when there is a considerable amount of air on, so that the strength of the fumes may pass off before the house is shut up. Perhaps Hamburghs are most easily thus injured.

Specimen Caladiums and Achimenes (*Idem*).—For good specimens of Caladiums proceed thus:—Keep the rhizomes, as lately described, free from cold in winter, shake them out and repot as soon as they begin to move, potting them singly in small pots, to be afterwards placed singly in larger pots, or three or four plants at once in a large pot. Drain well, use turfy loam and peat in equal portions, with about one-sixth of old rotten cowdung and silver sand, and give bottom heat until the leaves come to their best. To grow good specimens of Achimenes, select the tubers, place them singly in well-drained pans or pots, using light rich soil, and set them in a temperature of from about 60° to 65°. When the plants are up and from 1 to 1½ inch in height, plant them in soil similar to that recommended for Caladiums, in their flowering pots, the small kinds at 1 inch apart, the larger kinds at from 2 to 3 inches apart, and plunge in a gentle bottom heat of about 75° or 80°, and a top heat of from 60° to 65°, with a rise from sunshine. No sun must touch the leaves, or those of the Caladiums either, when damp. Air should be given early, for if there is confined moist air in the place, and the sun strikes on the plants, the leaves will be spotted to a certainty. When hardened off, for conservatory, &c., they will not be so easily affected. Achimenes for late work may be grown well in a cold pit after the end of May.

Tree Fern, &c. (*Diana Milner*).—Dicksonia antarctica, one of the handsomest of the tree Ferns, would thrive admirably in a fernery in which the temperature falls as low at night as 38°, but is usually about 40°. Excellent young plants may be had for 5*s.* of any of the principal London or provincial nurserymen. Adiantum trapeziforme, macrophyllum, and tenerum would not flourish in the temperature named; they require a heat of from 50° to 55° at night. Adiantum Sanctæ-Catharinæ is a handsome Fern, introduced since the "Cottage Gardeners' Dictionary" was published; but it requires a stove temperature. It is not very expensive, costing from 5*s.* to 7*s.* 6*d.* for a nice plant. The frond sent is that of some Nephrolepis, but not being in fruit we are unable to say which.

Tanning Garden Netting (*F. A. M.*).—Boil it half an hour in a strong infusion of oak bark in water.

Heating a Small Greenhouse (*D. Dougal*).—1, For such a house as you describe, 15 feet long and 8 feet wide, a swing sash below the apex at each end, say 2 or 2½ feet as the base of the triangle, will be enough for top ventilation. You may have a square of 18 inches as near the top as you can, if you would prefer that shape. This left always open in summer, and regulated in winter, would be air enough, with or without your proposed opening in the back wall. Two sashes in front should be made to move, or if you had four ventilators in the wall below your sashes, you might have all the glass in front fixed as well as the roof. 2, We think a £3 Hays's stove would suit you well. You must purchase it in London. 3, That is one of the drawbacks of patented articles. The stove, we presume, must be sent to Glasgow, if there is no place for sale there appointed, and the stove will only suit if the fuel suitable is sent from the emporium. Neither coke, charcoal, nor cinders will do. 4, A small iron stove with a chimney through the roof would answer for your place, but it would not be so cleanly as Hays's stove, and the latter would be safe with merely a gas-pipe from it into the open air.

Pelargonium Sports (*A Young Beginner*).—They are rarely permanent, being very liable under even slight changes of treatment to return to the original characters. A sport is no more liable to sport again than its parent.

Bedding Pelargonium, Calceolaria, and Verbena Cuttings (*Fred.*).—Cuttings of bedding Pelargoniums and Calceolarias put in now and forwarded in heat will flower finely in July or August, and throughout the autumn, but not so well as autumn-struck cuttings. It is not too early to buy Verbenas; pot them, and take off the tops when of sufficient length for cuttings, and both these and the plants from which they are taken would do for bedding out. It would be better to place the Verbenas in two-inch pots, as they are then much more easily moved; but they would grow more strongly planted out in the bed.

Gravel Walks Loose (*Idem*).—We do not keep loose gravel on our walks, as they would not be comfortable to walk upon, and would always have more or less of a rough appearance. The surface should be even, smooth, and of fine gravel, kept well rolled.

Lilium auratum Culture (*A. H., of B.*).—The bulbs we presume are now in pots, and if so, and these are of a suitable size, they will only require a top-dressing of rich soil; but if in small pots, and not yet potted the operation should be performed at once. A seven-inch pot will be suitable for a medium-sized bulb, and a nine-inch pot for a large one. The pot should be well drained by placing a large crock over the hole, on that some pieces of less size to the depth of 2 inches, and over them an inch or so of the rougher parts of the compost. If the bulbs are in pots, turn them out, and remove the loose soil, but do not break or injure the roots; place a few inches of soil in the pots, set the bulb in the centre, and cover the crown about an inch deep. The pot will not be full to the rim, which is all the better, an inch or two being left for top-dressing when the shoots are a few inches higher than the rims of the pots. The soil may consist of two-thirds turfy loam, and one-third leaf mould or very rotten manure, adding one-sixth of sharp sand. The soil should be kept moist until the plants are growing freely, when liberal supplies of water should be afforded. After blooming diminish the supply of water, and during the winter keep the soil moderately moist, but not wet, and protect from frost. Afford an airy, light position in a cold pit or greenhouse, or an open sheltered situation out of doors.

Flower-beds (*A Constant Subscriber*).—Both your proposed arrangements are good if you keep the heights of the rows correct. To make a quick display you would require to plant the general stock a foot apart, the Lobelias from 4 to 6 inches, and the Cerastium from 2 to 4 inches.

Heating a Pine-pit (*W. C. W.*).—Your two-inch pipes will do for bottom heat in your Pine-bed, 6 yards by 2. We prefer that these pipes should be surrounded with open rubble, and covered with the same to the depth of 2 inches or so, to having the pipes go at once through the plunging medium, because the heat is more equally diffused, and because the pipes would so dry the plunging medium that heat would not be well diffused. The pots should stand near the rubble. We would prefer tan or leaves to sand or gravel for plunging in; but the others will do, or even a bed of earth. It will be as well to have some pipes communicating with the rubble, that you may pour down water when a moister heat is wanted at the bottom. You can have the "Pine Apple Manual" free by post from our office, if you enclose thirty-two postage stamps with your address.

Names of Plants (*G. S.*).—Your specimen is what is usually called Scilla præcox, but we are inclined to agree with Sir J. E. Smith that it is only a starved form of S. bifolia. (*A. B. C.*).—2 and 8, Cupressus, but species not distinguishable; 3, Juniperus chinensis; 4, Juniperus rigida; 5, Cephalotaxus Fortuni; 6, Juniperus macrocarpa. (*Ardavon*).—Asplenium bulbiferum (?), and Pteris serrulata. (*G. F., and A Constant Reader*).—It is impossible to name plants from such fragments. Specimens in flower are required.

METEOROLOGICAL OBSERVATIONS in the Suburbs of London for the Week ending March 5th.

Date.	Barometer.		Thermometer. Air.		Thermometer. Earth.		Wind.	Rain in inches.	General Remarks.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

BREEDING GAME FOWLS.

(*Continued from page* 171.)

It is to be observed in breeding light and dark colours together, that the cock should be of the light and the hens of the dark colour, as in this case the hens being of the darker colour will rule the colour more than the cock. If a dark cock is used for breeding with light-coloured hens, the result will be few or no light-coloured birds, which clearly shows that the cock influences colour more than the hens do as a general rule.

Some breeders object to dub their brood cocks at all, but this is a mere matter of opinion.

In breeding in the spring of 1848, I tried an experiment on the sex of eggs, selecting eleven good eggs to produce all cocks; they were of the willow-legged breed of the Black-breasted Reds. The hen hatched ten healthy chickens on the 21st of April, out of the eleven eggs, and they all grew up to be cock chickens, and were the most pugnacious brood of this colour that I ever reared, constantly fighting.

Some breeders choose their finest "stag" to make a brood cock of, keep him undubbed, but dub all others, and put him on the best walk by himself with a few hens only, to try what sort of chickens he throws as a stag, before breeding from him as a full-grown cock at home. Many also try their best pullets in the same way before breeding from them as full-grown hens, putting them with their best stag. The old breeders used to try some of their stags by weighing them in to fight against full-grown cocks in a main, when, if they fought well against full-grown birds, they were good, if not, they were condemned as bad. The shortest-legged stags were used for this purpose, and at least three of them, as these look most like cocks, being more down on their thighs than the long-legged early-hatched stags ever are as a rule.

By mating the brood cock and brood hens about Christmas, they become well acquainted with one another, and the hens are well attended to by the cock by the proper time for laying eggs for hatching, which is in February and March. I generally mate my brood fowls two or three days before Christmas, putting only a few of the very best-shaped hens to the best-shaped brood cock—never more than six hens, of course; and I think this the best way of breeding first-rate stock birds.

When a stock of Game fowls has been bred in-and-in too long they begin to be slower in their motions, the hens and pullets do not lay so well as formerly, and they moult late and feather badly and slowly. When this is the case they should be crossed with a strong healthy brood cock, and the progeny by him retained instead of the older birds. All birds from a first cross are most vigorous if the cross is good, and best for the pit. Second, third, and following crosses are less vigorous and spirited than a first cross, as the first mixture of different blood always produces most vigour. By keeping two different strains always separate, a first cross may always be had when wanted.

In breeding it must be noticed, that the best-laying hens never breed the best birds—that is, hens which lay in winter are not the best to breed from, having exhausted themselves before the proper season. The best hens to breed good hard birds from, are those which do not lay at all (after moulting at the proper time), until the middle of February, thus laying their first clutches of eggs at the proper season for hatching.

As to the age of eggs for hatching, eggs will hatch easily, if well kept, at a month old, but this, perhaps, is rather too stale. My plan was to collect all the eggs ten days old, or fresher still,

and to put them into a large jar full of dry bran, sticking them points downwards deep into the bran, and thus keeping them in an upright position, and then placing the jar in a cool cupboard. When eggs were required for a sitting I chose the best-shaped of these, none of which were older than ten days. All eggs kept in this way I found to hatch well and without failure.

Game fowls, if healthy, should be in full feather by November, and should moult in September or October, feathering well and quickly, as healthy birds should do. Some are found too bare in moulting. Such birds are not so healthy. No Game hen if short in body and of the proper size can cover more than twelve eggs properly. I use eleven eggs to a sitting in cold or cool weather, and twelve in warm weather, and never more, though many give thirteen eggs. A little earth at the bottom of the nests, not too dry, assists in hatching the eggs. As with Pheasants, for nests I prefer short hay sprinkled with lime.—Newmarket.

(To be continued.)

BREEDING DARK BRAHMA POOTRAS.

(*Continued from page* 170.)

I mentioned last week the principal characteristics in shape to be attended to in breeding these fowls, and I propose next to make a few remarks upon the colour and other fancy points.

One of these, and of no small importance, is the comb, which, as it is more peculiarly characteristic than in nearly any other breed, ought to receive very special attention, but is, on the contrary, very generally neglected. I had a note a fortnight ago from a gentleman who has taken numerous prizes for Dark Brahmas last season, remarking that he found it almost impossible now to procure hens with good combs; and another only a day or two ago from one of the most successful exhibitors of the light variety, in which the writer observed that he now seldom saw a good comb in either colour, and that all Brahma combs were fast degenerating into "cup combs," and would, if not watched, soon lose their peculiar triple character. I quite agree with both the writers, and wish to draw special attention to the point before it is too late. I believe the evil to have arisen primarily from the various crosses which have been attempted with the idea of improving the breed, and which I shall notice by-and-by, and to have been since perpetuated by want of care. As it is, even where the triple character is apparent, the comb is too often a shapeless confused mass. Amongst fifty-three entries for cocks at Birmingham, I particularly noted that there was only one comb which could be called perfect (belonging to a bird shown by Mr. Boyle), and five more tolerably so. The others were all examples of more or less shapeless confusion. In a good Brahma comb, I need scarcely say, there should be three distinct divisions, each running straight along the head and evenly serrated. The centre division should be about double the height of those on each side, and thin, and the whole as small as possible, so as to sit firmly on the head, and not tremble every time the bird moves. An overgrown comb which shakes with every movement is very unsightly.

Even when the parents have had unexceptionable combs, it may be as well to caution beginners, and even some old breeders, that it is by no means easy to "grow" them in perfection upon the heads of the cockerels. There is a continual tendency to grow too high, or, what is still more ugly, to shoot out sideways. After comparing notes with several experienced exhibitors, I am of opinion that this arises from too much or too stimulating food. If there be more flesh-forming material supplied than is consumed in the general system, the remainder appears to go into the comb. At all events, the overgrowth I am speaking of appears more frequently in cockerels bred in comparative confinement, and is more rare where the birds have a wide grass run, to keep the bowels freely open, and work off any amount of feeding by active exercise. I can only point out the fact, each breeder must avoid the consequence as best he can; and it will be seen that the problem is a rather difficult one, for if the bird be underfed, it, of course, does not attain a proper size, whilst undue forcing leads to the result mentioned.

I wish, however, to express a decided opinion, that far more stress should be laid upon the comb of the Brahma at all exhibitions than is now the case, and for the simple reason that, as already observed, it is a marked characteristic of the breed. I am no advocate in general for laying undue stress upon "fancy points," I could wish that our general poultry-judging were very much more the other way; but where any point is one of the distinguishing marks of a breed, I contend that it stands upon a different footing; and I cannot understand why any gross defect in the comb of a Spanish or Hamburgh fowl should be instant disqualification, and almost any amount of deformity be tolerated in a Brahma. No one would think of giving a prize to a Hamburgh cock whose comb was not, at all events, passably good; yet the Hamburgh comb is approached in character by the Dorking, and is, therefore, far less peculiar and characteristic than the comb of the Brahma, which is altogether unique and peculiar to the breed.

I have dwelt at length upon this point, having a strong sense of its importance, a feeling which is shared, as I have said, by some of the most eminent breeders. I venture to ask for it the careful attention of our poultry judges, and would also like to invite the opinions of others of your numerous readers. I write in no dogmatic spirit, but simply from a strong feeling that unless more stress be laid upon the perfection of the comb, and very soon, that peculiar formation which is in my eyes one great beauty of a Brahma will speedily be lost. That it has real beauty few who have seen it in perfection will be disposed to deny.

My remarks on this head have taken up so much room, that I must defer anything concerning the colour of the plumage until my next communication.—Nemo.

(To be continued.)

INQUIRY.

Has any one applied for the eggs advertised in "our Journal," at 10*s*. 6*d*. per sitting, from birds of all the "crack" strains, and giving the address as M. Brooksbank, 4, Back Rolleston Street, Manchester? We are informed that it is about one of the lowest localities in Manchester, in fact, not a "stone's throw" from Pott Street, New Islington, notorious for the "Long firm;" that No. 4 is a cottage at about 2*s*. or 2*s*. 6*d*. per week, pretty clean for the neighbourhood; and that a few mongrel fowls are kept, which roost in the cellar.

CROSS BREED OF FOWLS.

I can from experience strongly recommend a cross between the Brahma Pootra and Spanish. I use a Brahma cock from a stock bred in-and-in for ten or twelve years, and common Spanish hens, costing 2*s*. 6*d*. each; the chicks are healthy, never naked in their chickenhood like their parents, come early to maturity, and are first-rate layers of fine eggs in winter, when eggs are generally scarce, as well as in summer; the pullets lay large eggs as compared with other pullets, and they make large handsome fowls. I have some in full laying weighing about 7 lbs. each. The cockerels at six months old always weigh more than 6 lbs. I killed some in November; one of them, five and half months old, weighed when trussed 5¾ lbs.; no shutting up, stuffing, or cramming, but running in the yard and feeding with the others. The pullets are close sitters and good mothers.

I sit my hens anywhere in small houses, like dog-kennels, covering the sides, roofs, and backs with tarred felt. To each house I have a small yard 3 feet 6 inches long, 3 feet wide, and 3 feet high, formed by means of laths. The roof is covered with tarred felt. Out of about thirty pullets put to sit last year, only one refused the nest.

The cross-bred fowls are very quiet, a three-feet wire fence being sufficient to keep them in. If I had had prime birds to breed from, and a good run, no doubt the result would have been better still.

I feed my fowls principally upon barleymeal and fine bran in equal quantities, and every day I mix with their food half a pint of finely powdered chalk, or half-a-pint of animal charcoal, costing 14*s*. per cwt., and I afford a small feed of oats or barley before they go to roost.

My fowls are kept in a yard covered with coke dust. The same yard has been occupied by them for five or six years; sometimes I have had in it as many as eighty or ninety at a time. I keep it perfectly sweet by occasionally dissolving in boiling water about 2 ozs. of McDougal's (Arthur Street West, City), "cattle plague soap," costing 6*d*. per lb., adding about three gallons of cold water, and watering the yard as one would a flower-bed. Before I adopted this plan, in wet weather the yard used to smell very offensively, not only to myself but to my neighbours; now it is always sweet. I keep the house free from smell by every day or

two covering the dung with dry earth powdered, and sprinkling two or three handfuls of McDougal's disinfecting powder, costing 10*s*. 6*d*. per cwt.; and although I only clean the house out every three or four weeks, there is no smell upon opening the door in the morning.

I write in the hope of inducing some who now keep mongrels to try this cross breed. I can assure them, once they do so they will never again keep mongrels; and from experience I can safely say that any person having twelve of these fowls will never be a single day in winter without eggs, no matter how severe the weather may be. My fowls never ceased laying during the late severe weather.—Pro Bono Publico.

BRAHMA POOTRAS.

In your answer to me, No. 308, page 156, you say your experience does not agree with mine, as you do not find Brahmas eat according to their bulk. In order to test the matter I have adopted your suggestion, and carefully kept account of the food consumed in four days by six Brahmas and twenty-three common farmyard fowls, the result will prove that Brahmas are enormous eaters compared with common fowls.

The Brahmas are confined in a run 36 feet long by 7 wide, the twenty-three common fowls in a run 48 feet long by 24 wide. They were all kept on bruised oats for two days, and the next two days on bruised barley. The result is as follows:—

TWO DAYS ON BRUISED OATS.

	d.
6 Brahmas, 18 pints, weight 5 lbs., value at 4*s*. per bshl. of 3 stones	5¾
23 Common fowls, 84 pints, weight 8¼ lbs., ditto ditto ditto	9½

TWO DAYS ON BRUISED BARLEY.

6 Brahmas, 7½ pints, weight 3 lbs. 14 ozs., value at 5*s*. 3*d* per bshl. of 52 lbs.	4½
23 Common fowls, 16 pints, weight 8¼ lbs., ditto ditto ditto	10

The birds are all adult fowls. This experiment proves that six Brahmas eat as much as twelve barndoor fowls of crushed oats, and as much as ten barndoor fowls of crushed barley. In fact, one Brahma will eat nearly as much as two common fowls, such as are called Dorkings in farmyards.

You recommend Spanish for confinement. If I give up Brahmas, may I ask if they lay as many eggs as Brahmas, and if they are hardy in confinement?—J. R. Beyton.

[We cannot understand why your fowls eat so much more than ours. Are you much patronised by small birds, or has anything access to the pen? When food is laid down overnight, rats often eat it. We cannot understand why the difference exists between oats and barley, both being crushed, or why the common fowls should eat more and the Brahmas less when fed on barley. We advise you to keep to the oats. They are better for the birds and cost less. We still say your fowls cost too much to keep, and think you will do well to try whole corn measured. This would be only an experiment. A pint of corn should feed a fowl three days.—B.]

INCUBATORS.

"A. H. S. W." makes a serious error when he assumes that the facts I stated in the Journal of Feb. 14th were not tested by means of a self-registering thermometer; on the contrary, I beg to inform him that they were, and I am anxious you should allow me a few lines to say this, as it may appear that I am careless in what I state, and am not to be relied upon. I think he ought to have ascertained this point from me personally before putting it forth that I was assuming.

I can further asseverate that the incubator I am working has not for more than a week past been higher in temperature than 106°, or lower than 95°; this is with the attention of three or four, certainly not five minutes daily, and I leave it from 11 P.M. until 7.30 A.M. without attention. The evaporation of water in the boiler is so slight that I have not found it necessary to add any water for nearly a fortnight; and this fact alone proves that the incubator works equally—when the machine is once in proper working order very little heat suffices to keep it on the balance.

"A. H. S. W." states that he found it quite impossible to keep my incubator always at the right temperature. I am free to confess that it is in the last degree impossible to keep it or any other always exactly at an equal temperature; but it is by no means difficult to keep it to a range of 8° or 10°, which is allowable, and is quite safe, so long as the medium is about 102°, and perhaps it will be remembered that I stated last August that I worked an incubator for two months without altering the supply of heat during the whole time.

No one can be more gratified than myself if "A. H. S. W." has really succeeded, as he believes he has, in constructing an "Eureka" incubator, one that requires little or no attention; but I very much doubt this, and am sorry to differ from him. I may say on my own responsibility and without fear of contradiction, that it is impossible to construct an incubator which will not be affected in some degree by the variations of external temperature. When warmer weather comes he will find his incubator subject to the same contingencies to which all others naturally are, and I argue that it by no means follows that because the heating source is at boiling point the eggs will therefore be at the greatest degree of temperature they will reach; for the simple reason, that being some distance removed from the heating source, as they necessarily must be, the distance between will be liable to be acted upon by outward temperature; and the comparatively much greater expense his incubator must involve to keep it continually at so great a heat, detracts from the value of the machine, as so much is needlessly lost.—John Brindley.

HYBRIDISATION—PLURALITY OF QUEENS IN A HIVE.

In investigating the various phenomena exhibited in bee life, we should ever be careful that our observations be accurately made, and the inferences drawn from them be in accordance with facts. This is especially necessary with regard to the subject of hybridisation brought forward by Mr. West, and also to that of a plurality of queens, alluded to by "A Lanarkshire Bee-keeper." With regard to the first, the subject appears to me to be entirely inexplicable according to any other hypothesis than this—taking for granted always that the Italian bee in our possession is itself pure and free of all taint—that the young queens meet with more than one variety of drones. The consideration of this question evolves some points of a very interesting character. I could wish that I had the facilities with regard to locality, of carrying out some few simple experiments to settle definitively the points still in doubt.

I was in hopes that your valuable correspondent "R. S." would, from his favourable position, do something in this way, as, I believe, it was his intention; but though some obstacles may have interposed hitherto, I hope he will renew his endeavours during the coming season, and favour us with the results.

There is one point about which all seem to be agreed—namely, the rapidity of deterioration in the Italian bee when kept in proximity to the English bee; and this is the case apparently when, in the circumstances, the probabilities all point in another direction, as, for instance, when the Italian element is in the ascendant. According to the doctrine of parthenogenesis, a ligurianised apiary should not deteriorate, even in circumstances where impuritics manifest themselves. A restoration to its normal condition, in the absence of all foreign influence, should even then be a matter of time only. Is there any apiarian whose experience uniformly coincides with this result?

I observe that in Mr. S. Bevan Fox's remarks on hybridisation (4th December, 1866), he leans to the opinion that the paternal influence diminishes with the age of the queen. In the case supposed by Mr. Fox—namely, if the hybrid queen had been superseded and her successor crossed by his Ligurian drones, of which he says there were large numbers close at hand, then, so far from that being a cause of the degeneracy he observed, it should, according to parthenogenesis, have increased rather than deteriorated the purity of the progeny. It is only in isolated apiaries, however, where such questions as this can be well determined, and the subject is one on this, as well as on other grounds, well worth prosecuting.

I see it is the opinion of the Editors (No. 305), that a distance of five miles is not beyond the limits in which hybridisation may take place. I should be inclined to doubt this, and would feel obliged by their kindly favouring us with the grounds of this opinion.

In regard to a plurality of queens in a hive, an old and a young one, we should always be careful in drawing inferences, as in the case narrated by Mr. George Fox, of Kingsbridge (18th April, 1865); and I have had several instances in my own apiary, where from the desertion of the queen and bees from one hive to another we may be deceived. In the case referred to, a queen was found encased at the entrance of a hive in which

its own queen, on inspection, was seen pacing about in perfect freedom. We must therefore carefully distinguish betwixt such accidental cases and others of a different character. I recollect of Mr. Woodbury having narrated the case of a plurality of queens, a young and an old one, in one of his hives during autumn some two or three years ago. "A Stewarton Apiarian" remarked at the time, without contradiction I think, that this was no uncommon occurrence; and I see "A Lanarkshire Bee-keeper," in a recent article, seems to be of a similar opinion. I do not think, however, that the experience of our most eminent apiarians justifies such statements. I am inclined to believe rather that it is only in exceptional conditions we ever find such anomalies, and consequently that they are of rare occurrence. In all my experience I only know of three cases. One took place during unfavourable weather prior to first swarming, and the other cases occurred in hives in which queens were reared to supersede defective reigning ones. In one of these cases both queens lived together apparently in perfect amity for upwards of three weeks, and both were fertile when I separated them. This is the most remarkable anomaly of the kind which ever came under my own experience or knowledge. Indeed, I am not aware that any similar case has been recorded by any other apiarian writer.—John Lowe.

[We have ourselves known several cases in which common queens have received Italian fecundation at a distance of from two to three miles; whilst Dzierzon, the very highest authority on this subject, states that many similar instances have been observed in which the nearest Italian stock was more than a German mile distant—one German mile being nearly equal to five English miles.

With regard also to a plurality of queens, the great German apiarian says that in a stock of bees only one queen is generally found, except when rainy weather sets in at the time of swarming, in which case a young one often hatches before the old one has departed, and several young princesses may then exist together for some time. But besides swarming time, we may also, in autumn, winter, or spring, occasionally find two queens in one hive, one of which, although generally old and more or less mutilated, is still borne with patience, whilst the other, a vigorous young one, is the reigning queen. The wings of the old one are, at all events, usually gnawed off through the attacks of the young queen; but her jealousy, which seems greatest immediately after hatching, ceases by degrees until, when she has become fertile, her whole attention and activity are directed to filling the brood-combs with eggs.]

TOMTITS versus BEES.

Some months since a plea was made on behalf of tomtits, that they only consumed the dead bees, and, consequently, did no harm to the bee-keeper. Liking the merry little birds and willing to give them the benefit of the doubt, though against my own convictions, I spared them, with the following result:—They have breakfasted regularly off my bees throughout the winter; they have tapped at the mouth of the hives with such vigour (I presume to induce the unfortunates to come out), that they have taken all the paint off the hive-entrances, and in the case of an old hive have made a hole nearly large enough to enter—in fact, they have much damaged them all. On Saturday I placed some comb full of honey in reach of the bees, who were busy in the sunshine, and was not gratified to see it devoured with the utmost apparent satisfaction by the birds.—C. C. Ellison.

NEW BOOK.

The Management of Bees. By W. J. Pettitt. *With a Catalogue of Hives and Apiarian Furniture.* Dover: Pettitt.

This is a new and enlarged edition of a pamphlet by Mr. Pettitt, the well-known hive-manufacturer of Dover, in which a brief discourse on "The Management of Bees," introduces a full catalogue, with engravings, of "Bee-hives, Bee-houses, and Apiarian Furniture," to the different items of which is appended a succinct description, with the prices at which they are sold. Many of the hives are unquestionably very ingenious, whilst we have no doubt that some are useful, and may be conveniently and profitably worked. A few of the names strike us, however, as being remarkable from having apparently been conferred on the *lucus a non lucendo* principle. For instance, the "Ayrshire or Scotch Hive" is actually delineated as being hexagonal; so that poor Dr. Cumming would appear to have made a very unnecessary confession when he admitted that the Ayrshire hives, which he described as hexagons, were really octagonal. "The Woodbury Observatory-hive" is also represented as being furnished with opaque shutters; whereas one of the main features of that gentleman's contrivance was the uninterrupted admission of light at all times. The "American" and "Canadian" hives likewise are doubtless very elaborate structures; but we may be excused for doubting whether they would not be repudiated equally by the genuine Yankee and the native of British North America as being nearly, if not entirely, unknown to the bee-keeping denizens of the New World.

OUR LETTER BOX.

The "Long Firm" Again.—In addition to our warning published last week we have had several letters informing us that the same "S. R. Reid," 54, Pett Street, New Islington, Manchester," had written for eggs, &c. In every instance the vendors required a post-office order payable in a fortnight to be pre-remitted, and in no instance did S. R. Reid comply with that wise requirement. Let all vendors act similarly.

Floor of Piosty Yard (*W. X.*).—As for reasons assigned you object to stone, slate, and bricks, use asphalt made in the way we have often directed for making garden walks. They are waterproof.

Soft Eggs (*Salop*).—As the hen has a supply of lime (it ought to be pounded chalk, old bricklayers' rubbish, or calcined oyster-shells), her egg-system is inflamed, and most probably from over-fatness. Put her upon low diet, only a little barleymeal, plenty of mashed potatoes, and lettuce leaves.

Egg within an Egg (*C. A. J.*).—It has frequently occurred, and requires no detailed notice.

Hen-feathered (*Hamburgh*).—A cock usually having sickle feathers in his tail is said to be "hen-feathered," and the tail in form is that of the hen of the same breed.

Vulture-hocked Brahma Pootras (*Subscriber*).—We believe vulture hocks are sufficient to override all merits, and to disqualify a bird however good he may be in other respects. He would have no chance against one without the appendage.—B.

Removing Eggs as Soon as Laid (*A. B. B.*).—We always remove our eggs a little later in the season. Our trouble is to make the hens forsake their nests. Three or four broody ladies take possession of the same, and growl lustily if disturbed.

Spurred Dorking Hens (*M. E. M. B. A.*).—The spurs you mention are not only unimportant, but they are very common in Dorkings, especially in large birds. Breed from such by all means, and do not cut the spurs in any way.

Scurfy Legs—Breeding Game Fowls (*Lanky Lad*).—A good country grass walk with plenty of green food is the best cure, if any, for scurf in the scales of the legs. Toast steeped in port wine or sherry is good. Some use a potash (potass), or soda wash for the legs. Vinegar is also often used as a wash for scurfy scales of legs. Pure-bred Black-breasted Reds seldom or never throw chickens with any brown on the breast. When this occurs it is generally from a cross of the Brown-breasted or Ginger-breasted breeds. Cock-fighters' breeds will always stand better than birds not bred for cock-fighting, as they match them in breeding for this purpose, and their birds are harder. Some exhibition birds are bred from cockers' strains, and stand remarkably well, and are more showy than the pit birds, and also larger and heavier. Exhibition birds are softer and more fleshy than the cockers' birds. Game may be easily bred hard by choosing hard short-bodied stock, and putting only a few hens to the cock, choosing spurred hens.—Newmarket.

Decayed Stock Hive (*Mens Conscia Recti*).—We could not discover the pin you speak of, and were therefore unable to identify the particular cell to which you refer. We were, however, able to perceive foul brood in the two darkest combs, although, doubtless, from its having remained in the cells during the winter it had assumed a more treacley appearance, and was of a thicker consistence than any which we have before observed. The breed in the third comb appeared healthy. We fancy that owing to the presence of the disease the stock must have dwindled very much during the autumn, although its doing so escaped your notice at the time.

Greatest Number of Hives in an Apiary (*A North Staffordshire Bee-keeper*).—I once counted late in the season, and after the autumnal destruction by brimstone had taken place, thirty-four stocks in one corner of an orchard half a dozen miles from Exeter, and the farmer's wife, to whom they belonged, told me she had ten more on a neighbouring farm. This extensive apiary, which flourished during many years, and in some summers had numbered eighty colonies, originated from a single swarm, which the good dame informed me she had in her younger days brought home from some miles distance on her head. My North Staffordshire friend is quite in error in believing that I have lost swarms through over-stocking.—A Devonshire Bee-keeper.

POULTRY MARKET.—March 6th.

We have still but a moderate supply, but trade is dull.

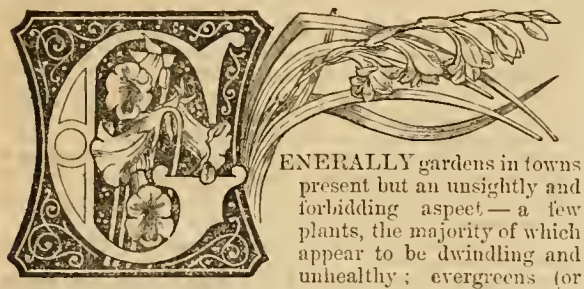
From observations taken near London during the last forty years, the average day temperature of the week is 50.9°; and its night temperature 33.8°. The greatest heat was 69°, on the 19th and 20th, 1836; and the lowest cold 17°, on the 17th, 1846. The greatest fall of rain was 1.11 inch.

TOWN GARDENING.



GENERALLY gardens in towns present but an unsightly and forbidding aspect — a few plants, the majority of which appear to be dwindling and unhealthy; evergreens (or rather ever-*blacks*) in galloping consumption, reminding one of the inmates of an hospital, rather than of vegetable life and vigour; the whole more calculated to excite feelings of melancholy than of pleasure and satisfaction. Sometimes, owing to repeated but abortive attempts to coax plants to grow, the entire contents of the garden are grubbed up and discarded, and the area which they occupied is paved or gravelled over, a few garden-pots, perhaps, and a few green sticks remaining for some time in a corner as memorials of the blighted hopes of the owner.

Having had an experience of twenty years in the management of a town garden, a few remarks, the result of that experience, may prove acceptable to those of your readers who may be struggling with the same difficulties with which I had to contend at the first; for during the earlier portion of that period I had many failures and disappointments to lament, but as I became acquainted with what, under proper treatment, would succeed and what would not, things gradually assumed a different appearance, and my garden became like an oäsis in the desert, and was uniformly admired by friends and neighbours, some of whom were encouraged by the hints I gave them to strive for a similar success.

I must, however, describe the general circumstances of the garden, first presuming that what I mean by "Town Gardens" are not such as are situate on the skirts and suburbs of a town, which commonly possess most of the advantages of the country, but such as are found in the midst of a town, and that a smoky town. Mine was in the heart of a large manufacturing town, containing with its suburbs (all of the same character), a population of 120,000. It was on the brow of a cliff of red sandstone, about 80 feet above the ground level of the streets below, the soil being not more than 2 feet deep on the average, and consisting chiefly of comminuted particles of the rock beneath. Its length was only 100 feet and its breadth 60, forming a parallelogram, the base of which was to the north, and bounded by the house; a considerable portion of the western side was flanked by lofty buildings, and the remainder of it by a wall about 7 feet in height; almost the whole of the eastern side had a similar wall, but there was against it in the adjoining garden a row of stately Elms, which had arrived at maturity before steam was introduced into the town to any extent. The south end, on the edge of the cliff, was enclosed with a dwarf wall and iron railings, through which, when standing near them, the spectator had a view of rows of smoking chimnies bristling throughout with larger and more aspiring columns, from which volumes of black cloud were occasionally belched forth. I had not only to contend, therefore, with the soot which fell from similar chimnies round about me, but sometimes with a horizontal stream of smoke, which flowed in from the south, filling us with smuts, though I am happy to say that the wind prevailed less from the south direct than from any other quarter.

These were difficulties to encounter of a sufficiently formidable character. I found the garden when I succeeded to it consisting almost entirely of gravel, with a decapitated Sycamore near the end, a stunted Abele Poplar in a corner, and little else. I observed that the attempts at grass plots in the neighbouring gardens consisted of tufts only here and there, patches of the bare soil being chiefly prevalent. Nevertheless, I determined to try one. I had a quantity of rich soil introduced into the garden, and formed beds for flowers along the western and eastern walls, a narrow one also at the south end, and three or four small parterres in the centre, which were surrounded with fresh turves from a neighbouring meadow. A broad gravel walk skirted the beds along the eastern and western side and end, with a bend or sweep from it dividing — the lawn shall I say?—no, but more modestly, the grass plot, into two unequal portions, the smaller one, containing the Sycamore, being in the south.

Let me here observe, for the benefit of country amateurs as well as those of a town, that a gravel walk should always be wide enough to allow three persons abreast comfortably to perambulate upon it. If there be four persons strolling about they can easily go in couples; but if there be three, and the walk is only wide enough for two, one must trudge before or follow behind in solitude, which is anything but agreeable.

The garden being thus laid out, the next thing was to stock it, which I did with plants of various descriptions, and a few shrubs and evergreens; but now commenced my trials. The first arose from the turves introduced, which, besides containing many troublesome weeds, were thickly sown with the larvæ of the crane fly, or daddy long-legs, the grub of which is voracious, and most injurious to the soft and succulent roots of grass and of all herbaceous plants. Everything drooped that was attacked by them. I was not then acquainted with a simple mode of destroying them, which is by watering them in the spring season, when they are in the grub state, with a weak solution of ammonia, or they should have had *quantum suff.*; but I kept them under by watching and destroying them as they came out of their holes, which they do in the twilight of the morning and evening (chiefly at the latter time), during the last days of August and throughout September. The fresh-emerged flies are also easily taken early in the morning, before they have laid their eggs, by hand-picking; for they are a dull fly if the weather is frosty or damp, but if it is dry and hot they are brisk and lively, and will not suffer you to approach. I was much assisted, also, throughout the spring and summer by the starlings, which appeared to know instinctively

where the grubs were concealed, and made good havoc among them.

I soon discovered, also, that the beds on the grass would not answer, independently of insect depredations. The sun was hot upon them during a fine summer's day from morning till evening, there being no shade from the walls as in the side beds, and they were soon scorched up, being upon a rock with no depth of earth. They were also much injured by gales of wind, which came from one or two quarters round the neighbouring buildings with concentrated force, and broke the plants to pieces. I therefore abandoned the centre beds, and sodded them over in the autumn with turves, which I was careful to have procured from a different locality. Nevertheless, the next spring I had an inundation from them of a grub of a different species; it was like a caterpillar in appearance, about 1¼ inch in length, and moved on its feet as rapidly, but it had a tail like a rat, nearly as long as its body, beginning with the same thickness as the body, and gradually tapering to a point. They soon found their way on to the gravel walks, and as they could not climb the tiles which bordered both the grass and the beds they were easily swept up and destroyed—in quantity a full half-peck. I never before saw any grubs like them, nor have I ever seen any resembling them since. Their length, including head and tail, was upwards of 2 inches in some of them.

I still had a great difficulty in keeping my grass alive; it was frequently watered, as also were the beds, but it seemed to scorch up the more with watering, as likewise did the plants. I was soon convinced by experiment that the fault was a too slight watering—not that it answers to deluge the plants, and let the water run away; they require, and the grass especially, a continued soft shower. I had, therefore, a tap laid on, and procured a sufficient quantity of india-rubber tubing to enable me to direct the water from the tap to any part or corner of the garden. India-rubber is far better than gutta percha, and little more in expense. The latter is not nearly so flexible as the former, and is apt in dry weather to burst, and become useless. I had a fine rose to fix on to the brass spout, to receive which I had an iron rod with a curl or two at the top, which I could stick into the ground and remove from one part to another; and I contrived to fix the brass rose to the curl at top in a perpendicular position, so that when the water was let on it spurted upwards like a fountain some 12 or 14 feet in height, exhibiting beautiful rainbows if the sun was out, and falling in a soft shower of minute particles on everything within a radius of 10 feet. If there was a breeze it was wafted in one direction or another beyond that radius; and by leaving it in each place before removal to another at least for half an hour, the whole garden became gently and thoroughly saturated in the course of an afternoon; for I did not begin to water until the shadows from the western side began to draw on to the grass, and there I always began first. Twice a-week, though I kept the grass well mown, I found quite sufficient watering even in dry and hot weather to keep all green and flourishing. For the trees I had a different nozzle to the spout, by which I could send the water with great force on to the stems and branches, taking care not to destroy the leaves, and by this means they were in a great measure cleansed from soot and smoke.

Though things now began rapidly to assume a different appearance, I had yet to learn what would flourish, notwithstanding the smoke, and what would not. I had to ascertain this entirely by experience; for the numerous gardeners who attended the market, which is an excellent one for flowers and plants, I found knew little or nothing about it, their produce of this description being generally purchased by persons who resided in the suburbs, or for window-culture only in the town. I was repeatedly assured that a plant would succeed in the town, which I found to my mortification would not succeed at all; and this assurance came from parties too honourable wilfully to deceive, but they had no real experience of town culture themselves.

I will commence, then, with those plants which will best endure the test, among the foremost of which are *Dahlias*. All sorts flourish and blossom freely, but the hardiest are the yellow and the white, which also are not considered dainties by the caterpillars and earwigs, and used to be left in the ground by me throughout the winter, protecting them with a little dry litter only. If, however, the borders in which Dahlias are planted are backed by walls, they are drawn up to an inconvenient height—5, 6, and even 7 feet. To remedy this I latterly planted only the dwarf kinds, from 1 to 2 feet only in height, in open situations; but these grew to 2 or 3 feet in height, and answered very well, only they required to be taken up for the winter.

I may here remark that most plants which grow to the height of 2 or 3 feet, if near a wall, will bend away from it, especially in hot weather, evidently seeking for a freer circulation of air. About half a century ago I remember a Sir Richard Phillips maintaining a sharp controversy with another philosopher, whose name I forget, on the question whether plants are *pushed* up or *pulled* up. Like the two knights in the fable who tilted furiously at each other on the momentous question, whether a shield on a certain statue in view of each was gold or silver, so these assailed each other with similar fury and a similar result, impartial readers coming to the conclusion that both were in the right, and that plants may be both pushed up and drawn up. The fact, however, which I have just stated of plants bending away from the perpendicular when a wall is near, shows clearly that there must be attractive influences from without the plants, as well as the propulsive ones from within.

Whilst on this subject I would notice another fact, which may interest the general reader. Years ago, when "my lines had fallen in pleasant places" (as, indeed, I am thankful to say they have now), I built a parsonage-house in the letter L-shape, and in the angle, where there was on one side a blank wall with a south aspect, I planted a Pear tree. For the first three or four years it did not flourish, the reason assigned by gardeners being, that the spot was too dry, being protected from the west and south-west rains by the other side of the building. After this period, however, its growth improved remarkably, and it bore excellent fruit. A few feet from the stem of the tree there was a well, on opening which, to repair a pump that was supplied from it, I observed that the Pear tree had sent forth a single branch of its roots to this well, down which it had to descend fully 10 feet before it could reach the water, and thus I accounted for the favourable change which had taken place in the growth of the tree. It would, however, have been a nice and knotty point for the doughty philosophers just referred to, under which power the tree was influenced in this instance.

Chrysanthemums likewise will endure the smoke, more especially the bushy sorts with small flowers. They like to be frequently removed; they need not be raised from cuttings, but succeed well by division of the roots, of which, indeed, they are all the better; the flowers dwindle if the root is too large. My plan was to shift them every spring, and make them change places with the Dahlias, giving to each hole, for both plants, a little fertilising compost.—Philokepos.

(To be continued.)

PLANTING PEAR TREES.

QUINCE AND PEAR STOCKS.

(*Concluded from page* 174.)

Now for the Pear stock. I have nothing to say against it where the soil and climate are favourable, when the space is not small, and when immediate production is not desired. The Pear tree delights in a strong loam, the subsoil a marly clay, or even gravel, free from stagnant water. On light soils, with a ferruginous sandstone bottom, it may grow and occasionally afford good crops, but it never thrives; and yet it does so on light soils, the subsoil of which is marl, or of an otherwise calcareous nature, or gravel free from sand and superabundant moisture. On a wet soil it may live, but does not thrive. The Pear on the Pear stock is longer-lived, and some say furnishes a greater produce than on the Quince; but that is opposed to my experience, for I find that the largest and most handsome fruit, and, for the area, the heaviest crops, are borne by trees on the Quince. Such bear from the first, making a good return for the ground and labour long before trees on the Pear stock produce any quantity of fruit worth naming. In fact, planting an orchard of Pear trees is planting for another generation.

But what of trees on the Pear as pyramids? They are very well where the soil and climate are suitable; but they do not bear with such certainty, the fruit is not so fine as from trees on the Quince stock, and the trees can only be kept productive by frequent lifting, which, when they are becoming old, is not safe. They require much more room, and however well pinched, outgrow the space, and are then neither useful nor ornamental. The Pear on the Pear stock requires plenty of room to develope its full proportions; it is then longer-lived, more healthy, and any loss of production in the beginning is

counterbalanced by the heavy returns after a few years. I wish these remarks to be taken apart from the fact that some varieties do not thrive on the Quince; and though it may be desirable to grow such as bushes or pyramids, I think it is a pity to work a scion on a large tree, and then to keep it down, by frequently cutting its shoots, to the size of a stunted shrub. Would it not be more reasonable to work on the Quince, or something more nearly approaching the size at which the head is to be kept, instead of on the Pear? The Pear in its natural state is a tree which, though not attaining such proportions as the Elm, Beech, Lime, or Oak, is anything but low-growing; the Quince at its best is only a low-growing tree or tall shrub: hence Pear trees upon it as a stock can never attain such a large size as upon the Pear stock.

Apples on the Crab are only suitable for orchards, and for walls or espaliers where long shoots are desirable or required; whilst for dwarfs, pyramids, espaliers, and walls where long branches are not wanted, trees worked on the Paradise stock are better, for they fruit earlier, thrive where the Crab is unhealthy, produce finer fruit, and can be grown in less space. The Paradise stock is raised from layers, and its growth is not so free as that of the Crab, which is raised from seed. The Paradise stock has its roots near the surface, and these do not descend so quickly in bad soil as those of the Crab, which, from its very nature as a seedling, roots deeply; and in the case of hot, light, shallow soils the Crab stock causes canker in the trees worked upon it, whole branches continually dying off. On the Crab the trees are not more healthy than on the Paradise stock, for what suits one suits the other, with this difference, that the Paradise lives where the Crab will not. For instance, I have some pyramids on the Paradise stock, also on the Crab, about ten years planted; those on the Crab are cankered, and produce fruit as much "pitted" as the branches are spotted with canker, whilst those on the Paradise stock bear their half bushel of fruit without speck or crack. The soil is a shallow loam over gravel. There is no difference in the culture, and yet there is a great difference in the results. A good top-dressing of manure is quickly consumed by the trees on the Paradise, but the roots of those on the Crab have gone too far down. These trees are 7 feet high and 5 feet through.

Three years ago we planted some pyramids on the Paradise; they each bore half a dozen fruit in the first year, in the second a dozen, and last year one and a half dozen, except one kind, Lord Suffield, which would bear itself to death if allowed, and of this I thinned out the fruit to a dozen, and such fruit! —they were as large as a man's fist. The roots are so near the surface that the rains have washed them bare, showing how they liked the top-dressing. This year the trees must not be allowed to bear such a crop, for I want them larger. I may state that we have some planted so deeply that the junction of the graft and stock is covered; they are rooting from the Apple above this point, but I shall lift them and cut away the Apple roots. They cannot do better than they have done, and I fear the same result with them as with the trees upon the Crab stock if the roots are allowed to go down.

The Paradise stock exerts an influence on the Apple in the same manner as the Quince on the Pear, but in a less degree; but the former two being more nearly related, the check to the returning sap is not so great, and the growth more closely corresponds. I have not found the Paradise an unhealthy stock except when surface-dressings have been neglected; the roots then go down for moisture, or they perish from want of it.

The whole matter resolves itself into "C. C. E.'s" words, that "whether Pears on their own roots and Apples on the Crab are or are not better than on the Quince and Paradise," appears determined "by the size they are intended to attain and the soil they are to grow in;" and the question to be answered before planting a garden is, "Which are the best to plant?" I give my views below; others, I hope, will state theirs. Nothing can better illustrate my own ideas than the following: —About this time last year I was asked to give advice in the re-arrangement of an old country house and grounds. The house was decayed, the gardens old, and yet there were in the orchard Pears on the Quince stock, which bore exceedingly well. The junctions of the stocks and scions were covered; the grass had overgrown that part, or the trees had been so planted. However, they bore well, and were as large as any Quince tree I remember seeing. The house was pulled down and a new one is now being built, and is perhaps completed. A new garden had to be made, and a terrace garden and croquet ground were to take the place of the orchard, which had to be stubbed up. The soil is a good substantial loam, over gravel, and Apple and Pear trees, respectively upon the Crab and Pear stocks, thrive in it. To plant an orchard of Pear, Apple, Plum, and Cherry trees would not be advisable, for the family would need fruit of the kinds named many years before Pears on the Pear stock, Apples on the Crab stock, Plums on standards, and Cherries on the Cherry stock, would come sufficiently into bearing to meet its requirements, but I advised and planted an orchard of such trees. On both sides of all the walks in the kitchen garden I have planted or shall plant Pears on the Quince stock, Apples on the Paradise stock (the English Paradise, the French is worthless in our climate), and a few Cherries on the Mahaleb, and the walks being numerous a goodly number are already planted, and more will be placed there. Those planted are plentifully furnished with fruit-buds, and will bear this year if allowed. I have in addition planted a row of Pears, and another of Plums in a sunny open strip of land, about 70 yards long, the Pears on the Quince stock at 4½ feet apart, and the Plums at twice that distance; and I should have planted a row of Apples on the Paradise stock, only some of those from the orchard, also on the Paradise, were removed, and there are some standard trees. The wall trees were planted in the usual way. The bush and pyramid trees will bear and afford a sufficient supply of fruit until the orchard trees come into bearing. Had the bushes and pyramids been omitted I fear the gardener's post would not have been an enviable one. There is fruit for the time being and prospectively.—G. Abbey.

PELARGONIUMS OF THE PAST SEASON.

By this term I mean simply those of the greenhouse; all those which go under the names of Zonal, Bedding, or Nosegay Pelargoniums I have nothing to say about. The last season was so exceptional, so thoroughly hostile to all the occupants of the garden, that it was impossible to say which were good and which bad, for all were bad alike; even the old-established favourites looked poor and washed out, comparatively speaking. I must, therefore, pass them by with this one remark, that I did not see anything that struck me as likely, even in good seasons, to be of a particularly striking character. There are a few promising flowers this season, among them three by a new raiser, Mr. Groom, of Ipswich, which, I have been told by those who know such things well, are in shape and substance beyond anything that we have. I mean, then, to confine my remarks to those which are ordinarily known as Greenhouse Pelargoniums or Geraniums, and of these the varieties raised by Mr. Hoyle and Mr. Foster still take the lead. Others follow, but it is at a very great distance.

As far as I have been enabled to judge, the best three flowers of last season were—

1. *Charles Turner.*—A fine scarlet variety, with a pure white throat. The upper and under petals are of a fine orange scarlet. The upper petals have a deep maroon spot, the lower ones are plain. The shape of the flower is excellent, and the pure white throat gives it a very brilliant appearance. The variety is also of excellent habit and growth.

2. *Progress.*—A flower own brother to John Hoyle, but even better than that noble flower in its form. The substance of the petals is very good, and the whole habit of the plant very fine.

3. *William Hoyle.*—Certainly the very darkest variety that we have; in the style of Achilles. The upper petals are almost black, with a very narrow margin of light carmine; the centre of the flower white. Unfortunately, like its progenitor, the growth is delicate.

Of the other flowers of Mr. Hoyle's there were—

Albertine.—A very pretty flower, soft-looking in colour, and with the lower petals somewhat tinted with lake.

Decision.—Lower petals deep rose, tinted and shaded with a deeper colour; top petals rich deep maroon, narrow carmine margin, with a very light edge. A good and well-shaped flower.

La Blonde.—Rose lower petals shaded with deep rose, broad edge of rose.

Lady of Quality.—A refined flower; rose lower petals, dark maroon top, narrow margin of carmine

L'Inconome.—Another shaded flower, but of no particular character.

Mrs. Waite.—Bright pink lower petals; upper petals of a brighter and deeper shade; centre of the flower white. A good grower.

Nabob.—A fine-habited flower; ground colour a bright rose,

with very deep spots on the lower petals; medium-sized blotch on the upper petals. This will, I think, be found to be one of the best spotted flowers that we have.

Queen Bess.—Lower petals orange rose; upper petals deeper orange maroon, narrow border of carmine.

Queen of Gipsies.—Orange rose, tinted with a deeper shade of the same colour; maroon upper petals bordered with carmine.

Selina.—Lower petals crimson scarlet; top petals scarlet, shaded with maroon.

Sovereign.—Large white-centred flower; rosy lake lower petals; deep lake top, shaded with black.

Of these the best I believe to be Decision, Lady of Quality, Mrs. Waite, and Nabob.

All these are seedlings of Mr. Hoyle's, whose flowers are the only ones that I have had the opportunity of seeing constantly, so as to be able to form an opinion of their merits. Mr. Foster's flowers have not hitherto seemed to me at all equal to them in their general character. I believe that now, however, there is a great improvement in the strain by the introduction of fresh blood into it; and that, as Mr. Foster, jun., is as enthusiastic in the raising of seedlings as his late father. I have no doubt that we shall see his flowers more approaching those of Mr. Hoyle's than has hitherto been the case, if, indeed, we have not arrived at very nearly the farthest point that we shall see reached in this lovely flower. It is sometimes hard to expect any improvement, and yet so we thought half a dozen years ago; but how far short of our present standard are the flowers of those days. There is, indeed, one cause that may effectually prevent this improvement, which is rapidly affecting all florists' flowers—viz., that rage for bedding plants which is now so universal. Take the pages of this Journal. A goodly octavo volume has been written during the past twelve months on a little plant at which a few years ago everybody would have turned their noses up—Viola cornuta. I do not deny its being a pretty little plant, and useful for the purpose, but it only receives any favour because of its being used as a bedder. While this has been so largely written about, who has cared to make half the fuss about any florists' flower? We who remember the days that are gone may well feel aggrieved at this, and can only look on to discover some glimmering streaks of the dawn of a better day; for, though modern gardeners contend that bedding-out requires so much knowledge of colours and skill, florista' flowers need an amount of patient watching, of skill, of constant attention, which on the whole tribe of bedding Pelargoniums, Verbenas, &c., would be thrown away. Hence on every side one hears, "We haven't time or space for growing florists' flowers;" "I have so many thousands of bedding plants to prepare and find room for, that really I cannot grow them as I used." So the demand for Pelargoniums, Dahlias, Pansies, &c., is every year decreasing, and, as a natural consequence, the raisers of seedlings fall off also. Let us hope that "there's a good time coming," when both objects may be attained.—D., *Deal.*

PEAS AND CABBAGES.

I WISH to say a little more about vegetables, which receive my greatest care, and I will begin with Peas. I have sown Sangster's No. 1, Daniel O'Rourke, and Dillistone's Early at the same time on the same piece of ground, and no one could tell the difference. Of the three, Dillistone's I thought was the best, lasting in crop the longest time. That was five years ago; last year I sowed some of Dickson's First and Best at the same time and on the same piece of ground as some of what I call Dillistone's Improved, for I have saved a few of the longest and best pods every year. Dickson's First and Best came in six days earlier, which is a great object where early Peas are in demand; but for a crop I should be sorry to give a preference to any of the sorts I have named over Dillistone's Early Improved. The pods are 4 inches long, well filled with peas as large as those produced by Bishop's Dwarf; but the soil and climate of different localities exercise a greater influence than I could have believed possible had I not lived in other counties. For instance, a crop of early Peas is often over in England in a fortnight; but here in beautiful Wales I have gathered for seven weeks from Peas which had first come into bearing in the end of June.

I saw by a late number that Messrs. Stuart & Mein recommend sowing Coleworts as soon as the weather and state of the ground will permit, in order to allow them time to make fine heads before the winter. I used to sow the seeds in the first week in April, but the plants were then always too forward for me. With every spare piece of ground cropped in March (for I must economise every yard of kitchen garden in order to supply a large family throughout the year with good vegetables, including Potatoes, from an acre of ground), Where am I to plant those early Greens? is a question I often ask myself. I must wait until the early Peas and Potatoes, Spinach, &c., come off, or plant between the rows, and this I often do. Accordingly I never sow my Coleworts, &c., until the second week in May, and I cut fine heads of the Ulm Savoy in the first week in October. The soil is very light, with a gravelly subsoil.—T. ELCOME, *Rhug Gardens, Corwen, North Wales.*

[Our correspondent, on again referring to Messrs. Stuart and Mein's communication, will perceive that their recommendation had reference to the different varieties of Sprouts, and more particularly to the Fearnought Cabbage.]

PEACH-TREE BUDS.

THERE are some Peach trees, like that most beautiful Nectarine the Elruge, which have abundance of bloom-buds, and leaf-buds always among them. There are others, like the Stanwick and the White Nectarine, where the blossom-buds are to the leaf-buds as fifty to one. Such trees soon grow out of bounds, and the shoots after a year or two are weak and spindly, unfit to carry fruit. Now, will Mr. Bréhaut tell me—First, What to do with an old tree of this kind? If the attenuated shoots are cut back they throw out no leaf-bud and the stumps die. Is it possible by cutting a straggling tree very closely all over to obtain a fresh sprinkling of shoots from the main stem? or is it the best plan to cut it down like a Fuchsia for one strong shoot from the base?

Secondly, It would be of still more service if Mr. Bréhaut would say how this superabundance of bloom may be prevented, or, in other words, how leaf-buds may be secured where they are wanted. We want two on each shoot, one at the extremity to feed this year's fruit, and this extreme bud you are sure of, if you have not in the preceding summer pinched your shoot too hard. It, however, you have pinched back so far as to take off a full-grown leaf, then in all probability you will have a naked branch of useless blossom, with even a bloom-bud at the top. This, however, may be prevented, as I have said; but another leaf-bud is wanted no less towards the base of the shoot, to grow into the replacing shoot of next year. This bud, perhaps, half the branches of the trees I have mentioned are without. Can any plan be suggested for securing this leaf-bud at the base? Will amputation early in the season of half the leaf which attends a bud? or will anything else have this effect upon it?—WYESIDE.

[It not being stated if the Peach trees in question are orchard house trees, or in a heated Peach-house, or on the open wall, it is difficult to deal with this subject except generally. The trees mentioned do not differ in their habit of growth so as naturally to produce the results stated. On the contrary, the Stanwick is here our very strongest Nectarine. Leaf-buds occur at the points of every one of the eight classes of Peach shoots, except in one case, that of "barren or blind spray." This is known by its single blossom-buds, slender habit, and dormant buds at the base. These last, in the Peach, are seldom developed after one season. Opinions differ whether to retain or cut away this class of shoot. All, however, agree that it is a sign of premature decay in the tree, however caused. As the trees are stated to be old, may not this, in part at least, account for their condition? Should they be old favourites, I cannot recommend their being wholly cut down. Doing so rarely succeeds, though the kind of stock they are on makes a difference. Rather encourage any strong wood-shoots, train them vertically, and as they are able to absorb the sap, cut away the older portions gradually this summer. If some fruit be desired (which is a pity), retain those clusters of bloom-buds without accompanying leaf-buds which lie close to the branches. They will bear and then dry up. An excellent way is to graft some young wood by herbaceous approach wherever possible. It is easy to do so in July, and the proceeding is very effectual in reforming a tree.

Leaf-buds are often wanting at the points even in the best pruning, with or without clusters of bloom. At the winter pruning it is not always easy to distinguish; even if left they are the most liable to be brushed off by contact with passers-

by. Sometimes they drop off from want of regular watering, or from attacks of aphides, &c. Who can tell us why they should occur in some places, and bloom-buds in others? M. Grin asserts that he can fix them at the base of spurs by bisecting the stipularies at the points of the shoots. I do not go so far, bnt venture to state, that if pruning by alternate shoots be practised (as recommended by me in the "Modern Peach-Pruner")—that is, if two shoots be left on each spur and these shoots be stopped at four leaves as soon as six full-sized leaves are developed, and the second growths at two more leaves as soon as four more leaves are seen, at the winter pruning an abundance of buds will be seen; and if then the best-looking shoot be left long to bear, and the other be cut to two wood-buds, or eyes, for succession, the want of terminal leaf-buds complained of by "Wyeside," is reduced to a minimum. You should always have two shoots on a spur.—T. Bréhaut.]

AVOIDING CUCUMBER FAILURES.

From the symptoms detailed by "An Old Subscriber," at page 86, I should be inclined to say that his Cucumbers are too wet at the root, or have too great a bulk of inert soil to grow in. It does not seem possible that they lack bottom heat. If this were the case, it would be a sufficient explanation of the failure. Cucumbers will certainly fail as detailed, let the bottom heat be never so well regulated, if the soil be sodden or effete. I hope your correspondent will forgive me, if I proceed "to lay down the law" rather confidently for the management of winter Cucumbers.

In the first place, I recommend his box for holding the soil to be of wood; the bottom of ours, two-inch plank, has lasted eight years. Secondly, The box should not be more than 18 inches wide, or at the very outside 2 feet. Thirdly, The depth of soil from September to February, should not exceed 9 inches. The reason for this is simply that the plants should at all times throughout the winter have a perfect command through the medium of their roots over the moisture in the soil, so as to necessitate watering twice a-week, or once at least.

Perhaps a few facts in illustration will assist your correspondent. From such a box, a section of which is just 18 inches square, and its length 40 feet, heated by one pipe, we have at all times abundance of Cucumbers. We have had plants for two years in bearing, the stem becoming as thick as a walking-stick, corrugated, and rough as cork. Plants turned out of pots in September have been bearing steadily since the first week in November; in fact, their fault is that they set too many fruit, if that which is so easily remedied be a fault. The plants in such a box are easily rested by being kept rather dry, and grow with fresh vigour when treated to plenty of water; they never go off as detailed by your correspondent, because the growth is firm and short-jointed. I may remark that our pit is a low one sunk in the ground, the glass very flat, and lean-to. Such, however, I do not by any means recommend; the sun scarcely ever strikes on the soil, which is a fault, no doubt, bnt cannot be remedied without considerable expense.

I am confident that more Cucumbers are unfruitful, and go off diseased in winter from the cause indicated, than from any other—namely, from having too large a bed of soil to grow in; and the remedy clearly is to grow them in narrower boxes with plenty of drainage, and the bottom heat unconfined—that is to say, ventilation must reach the roots. Although I have never been obliged to do so, I have no doubt but Cucumbers could be grown very successfully in pots in winter, because the roots could be kept together, and the plants would be completely under control.—W. D. Wynyard.

"An Old Subscriber's" Cucumbers appear to me to have failed owing to his allowing the border to become overcharged with hot steam from stagnant water in the tank, as well as from over-watering, and, it may be, allowing worms to breed in the border.

I do not like heated water under early Cucumbers. Two years ago I had some pits of Cucumbers in just such a condition as that which "An Old Subscriber" describes, the plants flagging and dying off, do what I would. I took the water out of the tank, lowered the temperature under the border, gave more heat above, and presently there was plenty of fruit. Last October we made up our bed for Cucumbers in a house 22 feet long by 12 wide; the border was covered with slate, on which was placed 9 inches of rubble, then some good thick sods, and above these 2 feet of compost. All went on well till the plants showed fruit, when they began dying back and flagging. We at once took out the border and found the sods on the rubble as full of water as they could well be. This was on account of their being too sun-dried to allow the water to drain off. We replaced them with new sods, repaired the border, and since then the plants have done well.

I should have mentioned that in consequence of the border being so saturated, the soil was full of worms, which rendered it too sour for any vegetation. To destroy them we water with a mixture of mustard and lime, which kills them at once, and does the plants good. If "An Old Subscriber" were to take the water out of his tank, lower the bottom heat to from 75° to 80°, and keep a top heat of between 80° and 85°, taking care at the same time that his border be properly drained, and the soil in a good, sweet condition, and free from worms, he will, I am sure, not complain long of so little success in the winter culture of the Cucumber.—Thomas East, *Wolveton House, Dorchester.*

I have witnessed in some of my plants the symptoms described by "An Old Subscriber," but at a different season. I have two houses in which I grow Cucumbers. One for early work is about 11 feet wide, 11 or 12 feet high at the back, and 4 feet high in the front, and is heated by hot water. In this house I have never witnessed the disease referred to. The other house is a low span-roof used for bedding plants in the spring, and planted with Cucumbers at the end of May. The Cucumbers receive very little heat except sun heat, of which I give them plenty. Now, in this house I have frequently seen the disease, from which the plants seldom recover. I ascribe its presence to the damp, stagnant state of the atmosphere in the house, while in the other case I think they are free from it, because the house is larger, and the circulation of air quicker; but I must say the house for early work is not a profitable one, because of the great amount of fuel it takes to heat it.—Ivo.

EARLY PEAS.

Your correspondent "Ronnoc," whatever may have been his intentions, must certainly have misled many readers of the Journal who have not tried our new Early Pea, had his reported trial and failure been permitted to pass unchallenged. We now discover, after reading his letter in the issue of February 28th, that from an imperfect knowledge of varieties he has confused our new "First Crop" Pea with an old variety introduced by us about sixteen years since, and then named "Carter's Earliest." Your correspondent, however, thought well to insert the word "first," making it read "Carter's First Early;" and as he does not inform us that the Peas he procured were in sealed packets, we can only conclude he was supplied with the old variety by his seedsmen. This sort we do not now maintain to be a first early, as there have been numerous improvements in early Peas since its introduction, but "Ronnoc" is again in error when he states the "quality" of our Pea to be inferior to Sangster's No. 1, as its general cultivation in preference to the last-named variety is abundant evidence of its superiority.—James Carter & Co.

My experience is very different from that of your correspondent "Ronnoc." I sowed on the same day Carter's First Crop, Dillistone's Early, and Sangster's No. 1 Peas side by side on just the same aspect as "Ronnoc," and Carter's First Crop was the first to bloom, and three days earlier to gather.—Caleb Silcock, *Gardener to T. Wardle, Esq., Macclesfield.*

CURRANT TREE CULTURE.

After reading the paper on Currant culture in a late number of the Journal, I think it may not be amiss to say a few words upon this subject for the benefit of young amateurs.

I have several standard Currant trees which for some years had borne either sparingly or not at all, and I had pretty well determined upon grubbing them up; but I thought I would give them another year's chance under different treatment, for it occurred to me that if Mr. Rivers's plan of summer-pinching as detailed in his "Miniature Fruit Garden" were so good for Apples, Pears, and Plums, why not also for the humbler Currant? Accordingly, throughout the summer of 1865 I kept them regularly pinched in strictly after Mr. Rivers's directions for the other trees named, and in 1866 I was fully rewarded for

my trouble, for anything more beautiful in the way of fruit-bearing than these hitherto-barren trees I have seldom looked upon. They were, both when in fruit and blossom, the admiration of all who saw them.

Since the pinching plan has been adopted upon the trees in question, no winter pruning has been necessary, and they are showing now every likelihood of being, with the permission of the sparrows and the spring frosts, as abundantly fruitful in 1867 as they were in 1866.—Beta.

In a communication from a correspondent signed "J. T.," on propagating and pruning Black Currants, I am not a little surprised to find him saying, "The Black Currant likes plenty of sun and air, and does not succeed so well as the Red Currant in the shade." So far from sun and air being indispensable for the successful cultivation of the Black Currant, and so far from its requiring in all cases the treatment which he describes, I give an instance to the contrary. The sun's rays never reach the Black Currant bushes planted in the orchard here, quite under the shade of Apple and Pear trees, from June, when the trees are in full leaf, until after the fruit is gathered, and all who see the produce declare they never saw such fine Black Currants. The bushes bear immense crops of large, equal-sized berries.

My object in bringing this fact under the notice of your readers is that they may be encouraged to plant any garden ground that may be shaded, with the utmost confidence of success.

It may interest your readers to know that plants of Cineraria maritima, without any protection, have withstood the late severe winter in an open border on the east coast of Scotland.—H. R., *Fife*.

CAUSE OF THE POTATO DISEASE.

I am fond of Roses, no one can be more so, and Mr. Radclyffe is fond of Roses; but, then, if he were to grow a multiplicity of Potatoes, he could not find sufficient room for Roses; and if I were to cultivate as many kinds of these as Mr. Radclyffe does, I could not find sufficient room to grow and study the more lowly, though valuable, Potato. I am no final-cause man either; to me it would be distressing not to think of beyond.

However, I am called upon by Mr. Radclyffe, at page 144, to enlighten him upon "the great mystery of the natural world;" but I wish he had deputed the task to more competent hands. I always held that the spot on the leaf was the cause of the gangrene in the tuber; but nature's laws generally admit of two methods of inquiry, philosophers call them Induction and Deduction—ways leading to the same end by different tracks.

In the first year of the disease I was living at Stanton Lacy, near Ludlow, and we had a large piece of ground planted with a then favourite Potato of mine, called the Birmingham Blue. I prided myself on the appearance of the crop, and had almost begun to calculate the money it would return in the shape of bacon when consumed by the pigs, when the lightning and the thunder came, and in a few days afterwards the tops of the Potatoes were black and offensive in their odour. From annual observation ever since, I have invariably found that the leaves of Potatoes show the fatal spot in close thundery weather; merely wet or damp weather does not cause the leaves to become affected, and I have never found the tubers diseased when the foliage has escaped being smitten by, as I believe, the electric fluid. For instance: last season the haulm of the Early Ten-week was ripe and gone before the lightning came, and although I allowed the crop to remain in the ground side by side with the other kinds to the last, not a single tuber became affected. The conductors were not there? Those which remained of the first-early Potatoes raised on warm beds, escaped also for the same reason. Not so the produce of the sample of the very same seed and sorts in the garden. Their tubers became affected more or less, as I have already stated, in consequence of the foliage being sufficiently immature and green to allow it to become stricken. I have always found it to be so, and this seems to me reasonable; for at the mid-state of growth the system is eager and susceptible, and the sap which feeds the roots then descends in its full flow; should it become vitiated at this time—it is at a mid-state that the disease shows itself—in the leaf, through the agency of some poisonous gas as yet unaccounted for in the atmosphere, the whole system of the plant and the tubers must become directly affected; and when the Potatoes are growing upon a wet undrained soil, or where raw manure is overstimulating their growth, so sure in those cases is destruction to be more fatal.

Now, as the Potato disease is sure to visit us annually more or less, and the later the better, and as it will ever be an impossibility for any chemical labour to prevent the atmosphere becoming charged with electricity, the wisest plan for us to act upon is to try and combat the disease by good cultivation. We must not give way to the too-common habit of allowing the soil to lie soddened, uncared for, and overrun with weeds and by all the children until the last moment in spring, when a hundred other matters require attention, to be then hurriedly and improperly dug, and to be planted in a similar manner. Worse still, the Potatoes themselves are too often subjected to a like carelesa treatment; they are, probably, kept in masses, heated, forced into germination, and deprived of their long premature shoots over and over again, till almost all the strength of the tubers is exhausted; then, as a final stroke, with some cruel crooked instrument, they are cut to pieces and placed along with raw manure in drills at planting, thus adding as it were insult to injury, and laying the surest foundation for disease that could possibly be thought of. Almost to a certainty it was this sort of ill-treatment which weakened the Potato in the first instance, and laid it open to attack. Eschew the practice as you would avoid the plague.

I may be thought to allow too much fancy to mix with my reason. I answer, that for the unknown phenomena of the disease the naturalist must sometimes theorise. If all the facts were known, nothing would be wanting but an appeal to reason. Imagination and appearances combined with experiment must be the landmarks, and this is the utmost I can offer by ways of elucidation. The cause will, doubtless, some day become scientifically known, be worked out in the chemist's laboratory, in the same way as hundreds of other hidden things in nature have been unfolded to us; and we need not consider it strange that this has not been done yet, for, to bring the matter home, it is not so very long since the real nature of glass and soap became understood through chemical investigations. Discoveries, too, are repeatedly made by men knowing nothing about chemistry.

I wish Mr. Radclyffe every success in his experiments with the dissolved vitriol, though I fear it will prove a failure in respect to eradicating the disease. No doubt it will kill the fungus on the tubers, and so it would on the leaf, though in my opinion the mischief is done before the fungus appears. I think the latter is an effect, and not a cause of the disease. Stephen's conclusions, however, are all true, except, perhaps, as regards the "skulkers." I should not feel so sure of them, and I do not like skulkers, but, honour to Stephen.

I will, in conclusion, quote a passage from a paper by Liebig (to whose writings and those of other scientific observers I am indebted for all my information relative to science), in the "Cornhill Magazine," where he refers to Schœnbein's discovery of ozonised oxygen. It will serve by analogy to support my idea of induction as regards the Potato disease. "Schœnbein had found that atmospheric air, when electrical sparks are passed through it, acquires new properties, the most noticeable of which consists in a most powerful affinity of its oxygen, to a degree hitherto unknown. In such air a number of bodies, such as silver, upon which oxygen in non-electrised air has no influence whatever, becomes oxidised. Now, the question is, How did Schœnbein arrive at the conclusion that phosphorus slowly burning in the air puts the air into the same state as the electrical spark? This conclusion was founded on the observation that electrised air smells like phosphorus, and, *vice versâ*, slowly burning phosphorus like electrised air. Furthermore, Schœnbein has discovered that the smelling matter possessed the oxidising effects. So the conclusion of the formation and existence of the same thing, the ozone, in two, according to their nature, totally different processes, originated in the observation of the same impression upon one of the senses, that of smell. If the leadership in this combination of ideas had been left to the understanding, the discovery most probably would not have been made, for the understanding would not have been able to reconcile these two facts—the formation of an agent possessing most powerful oxidising properties, through, or by the side of, a body as highly oxidisable as phosphorus."

Now, when I wrote to Mr. Gardner to come and see my Potatoes growing last season, I said, "Come quickly, as I seem to scent the disease in the air." My sense of smell is most acute; and in those seasons when crops have been much affected, a fortnight or so before the spotting of the leaves could be seen,

I have smelt the smell of electrised air most acutely. It appears to me, that the next thing necessary to arrive at the truth, would be to analyse the air when it is charged with electricity, at an early stage—when the leaves begin to show disease. It may be only the phosphorus that one smells; and is phosphorne an agent like electricity, to do deadly work upon the growing crops of Potatoes? It is known that electricity co-operates in the formation of rust upon iron exposed to moist air.—Upwards and Onwards.

[The foregoing is all ingenious; but how can the fact be disposed of, that Potatoes have been exposed to the same electric influences for centuries, yet the disease only appeared about twenty years since?—Eds.]

DISA GRANDIFLORA.

Having grown this lovely Orchid for some years I was, I confess, terribly taken aback by the statement in the Journal of February 21st, that Major Trevor Clarke had found it to be hardy. The note in the following number correcting the statement explains it. However, let me add that although not hardy, it will bear not only anything short of frost, but even a degree or two of frost without injury. My plants were this winter growing in a greenhouse with Pelargoniums, &c., and the first night of frost came so unexpectedly on us here that I did not light my fire. In the morning I was in a grievous fright, for, as I keep the Disas very wet, I expected to find them severely injured if not killed. The leaves were partly frozen I saw at once. However, I immediately covered up the house and set the fire going, and to my satisfaction found that, with the exception of a very slight scorching, they were all right. I have heard even lately one of our most successful plantsmen say that he found this a difficult plant to manage. I find it very easy. It requires light, air, plenty of moisture, and the very coolest of cool treatment.—D., *Deal.*

THE INTENSE COLD AND ITS CONSEQUENCES.

Derby.—The following plants have suffered here from the effects of the January frosts:—Ceanothus azureus, Garrya elliptica, both on a south wall, Golden Queen Holly, and Abies Albertiana, slightly touched. Our Roses are on their own roots, and pegged down; they were well covered with snow, so escaped injury. The Broccolis destroyed are Snow's Winter White, Grange's Autumn Cape, and Penzance. Later sorts have stood well. Cabbages, Savoys, and other Winter Greens are mostly killed. 24° below freezing was the minimum temperature registered here, the thermometer being placed 3 feet from the ground in a north aspect.—Charles Coombs, *The Gardens, Broadsall Priory.*

Ilford, Essex.—I send you, now that the damage can be more correctly ascertained, an account of some of the effects of the intense frost at this place. I am sorry that I cannot state the lowest temperature on the nights in which the cold was greatest, as the registering thermometer ceased to act correctly. We are nine miles from London, and about one mile from the Thames, on the north side; the situation is much exposed, and yet vegetation has not suffered to the extent that it has done in other parts in the neighbourhood of London.

Common Bays are scarcely touched, while at other places where I have been every leaf is browned above the snow line. The Sweet Bays in exposed places are very much injured, but in more sheltered situations they have suffered only very slightly. I am pleased with the appearance of the Aucuba japonica; a large plant fully exposed had berries on it which were quite green when the frost came, and I made sure that they would never colour; but they have changed to red, and are at this moment quite sound. I will send you a cluster or two, so that you may judge by their appearance of their capability of withstanding frost. I have never observed the birds attack the berries, although there are legions of sparrows, but other birds are scarce.

Amongst Tea Roses killed are Devoniensis, Canary, Madame Falcot, Adam, Souvenir d'un Ami, Maréchal Neil, and Vicomtesse de Cazes, as standards. Gloire de Dijon is the only standard Tea-scented Rose alive; Solfaterre (Noisette), a favourite Rose as a standard here, is dead; Celine Forestier (Noisette), as a standard, is safe. I pruned all the Hybrid Perpetuals this week, and found the wood largely discoloured just under the bark in numbers of them. Some of the more weakly and delicate sorts grown as standards are quite dead. I planted a bed of dwarf plants consisting of new varieties only a week before the frost, and none of them are touched. They were grafted on the Manetti stock planted up to the union, and afterwards mulched with half-rotten dung.

In the unheated orchard-house the roots of the fruit trees were made safe by being entirely covered with cocoa-nut waste. The pots were plunged to the rim before the frost, but to make all secure, a quantity of fibre was placed over the roots to the depth of 3 inches. Two large Aloes about forty years old in the house are very much injured; the young leaves are beginning to decay at the base and to fall over. In the kitchen-garden quarters the white Broccoli is entirely destroyed, and part of the Sprouting. A number of young plants of Pinus insignis in a sheltered corner are much cut up; other coniferous trees are safe, and most of them as green as they were before the frost came.—J. Douglas, *Loxford Hall.*

TIME REQUIRED FOR RIPENING GRAPES.

I wish to know if a certain given time should always be completed from the time of commencing to force until the Grapes should be ready for eating?

I have studied the "Vine-Manual," which proceeds from your office, and have recommended my man to go entirely by it; but I find that he, who has had charge of houses in this island (Jersey) for some years, is inclined to use a much higher temperature throughout, and last year he forced the Grapes in four months only. Also, provided sufficient heating power is attainable, should there be any difference in the length of time used for forcing Vines—say, in the north of Scotland and in the island of Jersey?—H. W.

[We incline to the opinion, that Vines will be forced in a shorter time in Jersey than in the north of Scotland, but we have had no experience in Jersey. In the higher temperature the Grapes will come a little sooner to maturity, but we consider at the expense of two losses, the use of more fuel to attain the higher temperature and the earlier exhaustion of the Vines. We should be obliged by statements of the experience of some of our Vine-cultivators.]

NOTES AND GLEANINGS.

We have been requested to state that the note inadvertently appended to the schedule of the Bury Show, which states that the prizes offered as cups, &c., may in some cases be received in money, was inserted in error, and that there is no intention of such an arrangement being carried ont. It is quite natural that those who give cups and other objects as prizes should wish that these should form more lasting memorials of the event than mere money prizes can; and we conceive that the prizes arranged in some conspicuous position in the Show would form no insignificant feature both of beauty and of interest in the Exhibition. As we understand many of the prizes are already purchased, it would add much to the interest attaching to them, were they to be exhibited in a group at one of the exhibitions of the Royal Horticultural Society in London during the season.

—— A work that has run through so many editions as Mr. Rivers's "Rose Amateur's Guide," does not require any further notice than the mere fact, that the ninth has just been issued; and we have no doubt but this new edition of a work which has contributed so much pleasure and instruction to so large a class of readers will meet with as great success and as hearty a welcome as its predecessors have done.

—— Mr. John Haythorn, late of Wollaton, died at Nottingham on Sunday, the 10th inst., aged 85 years. The deceased was head gardener to three Lords Middleton at Wollaton Park, near Nottingham. He was a Corresponding Member of the Royal Horticultural Society, and for several years a subscriber to the Gardeners' Benevolent Institution. Ten years ago he left Wollaton, and has since resided at Nottingham, and died there at the house of his eldest son, the manufacturer of hexagon net. He was married more than sixty years, and survived his wife only twenty weeks. He was the father of eleven children, of whom five only are living. His sixth son, the Rev. Francis Haythorn, was curate at Leiston a short time before he died.

—— On the evening of the 6th inst. a deputation waited on Mr. Simpson, gardener to Lady Maria Molyneux, Stoke Farm, Slough, and, in the name of the young men who had served

under his charge, presented him with a handsome microscope. In handing it over to him the deputation expressed the very great pleasure which they felt in thus testifying the high esteem in which Mr. Simpson is held by the gardeners who have served under him, and their appreciation of his worth as a horticulturist. Mr. Simpson returned thanks to the deputation, and, through them, to the absent subscribers for their kind attention, and he hoped by the faithful discharge of his duty towards his men to perpetuate the good feeling manifested in the valuable and much-valued gift.

WORK FOR THE WEEK.

KITCHEN GARDEN.

Asparagus, sow and plant if new beds are required; the beds should run east and west, for more heat will be thrown into them by the full exposure of one side to the noonday sun than would otherwise be the case. *Artichokes* (Globe), prepare a fresh plantation, if necessary, by deep trenching and high manuring, for if encouraged in this way they will continue, by judicious thinning, much longer in bearing. *Broccoli*, where any late spring Broccoli has escaped the general destruction, a portion may be taken up and forced in frames, in order that at least an occasional supply may be obtained during the long period of deficiency which must otherwise ensue. *Cauliflowers*, every means must likewise be adopted to forward them; those planted under hand-lights will derive some advantage from the protection of a mat in frosty nights. Where hand-lights cannot be afforded, flower-pots should be inverted over the plants at night. After planting out the winter Cauliflowers there generally remain a number of small plants—these, if pricked out in a cool and shady border, on rich soil, will form a succession, and serve as the connecting link between the principal winter plants and the spring-sown ones. *Cabbage*, let the soil be frequently stirred between the rows of young plants, and plant out from those sown in the autumn. *Carrots*, if the ground be in a fit state, sow the principal crops, and they are best in drills, not only as regards their growth, but also on account of the facility of hoeing and weeding. *Lettuces*, keep up a succession, and those in boxes in heat should be pricked out in a warm situation, in highly manured ground. *Onions*, transplant, taking care that no part of their stems is below the surface. Silver-skinned Onions should now be sown for pickling, the poorest soil in the garden is the fittest; work it when dry, throw it into high beds—the higher the better—and, after sowing thickly, tread it as hard as a turnpike-road, if possible. *Peas*, examine previous sowings, in case of injury from frost, for there is a particular period of their germination in which they are easily injured, as is the case with many plants in other respects sufficiently hardy. Successional sowings will require to be made. Sow, also, a few *Brussels Sprouts* for early use, *Cabbages*, *Cauliflowers* for a late crop, *Kidney Beans*, *Lettuces*, *Spinach*, *Celery* and *Celeriac*, *Parsley*, *Radishes*, and *Leeks* for transplanting.

FRUIT GARDEN.

Finish off the nailing of wall trees, and protect all as far as possible. Tie down a number of the weak and short-jointed branches of Pears and Plums on walls or dwarf espaliers. This will be found much better than the old or spurring-back method. In the meantime cut away all over-luxuriant wood close to the stem. Destroy all insects before the trees bud. Clear away all scale, &c., using a wash composed chiefly of clay, water, and sulphur on trees liable to insects. Proceed with the grafting of Plum, Cherry, Pear, and Apple trees, unless frosts are so severe as to cause the loosening of the clay. The latter will rarely drop off if the matting or bandage be well smeared over with a little grafting-clay before the ball of this substance be applied. Top-dress Hautbois Strawberries in beds, also other kinds where the ground is somewhat exhausted, as soon as the old leaves are cut away and the plants thoroughly dressed.

FLOWER GARDEN.

If Briars are required for budding Roses on, they should now be collected, trimmed, and planted in a reserve garden, or where they are wanted to stand for summer budding. All turfing, &c., should now be finished as soon as possible. Continue the pruning of shrubs, Roses, &c. When bulbs are making their appearance, the surface should be carefully loosened if the weather continues dry and free from frost. Lawns, or portions of them, having a hungry sandy soil, and liable to "burn," should have a slight dressing of some kind every spring; even common soil will benefit them, as it induces another tier—if I may be fallowed the term—of surface roots, of course increasing their volume. However, a dressing of marly or clayey soil in a highly pulverised state would obviate the tendency to burn. A slight dressing of guano has an excellent effect in such a case. Those who desire to have Moss and Provence Roses throughout the summer should now cut back a portion for that purpose, merely pruning away the parts which have budded. Superfluous suckers of Roses, Lilacs, &c., may be removed and planted out for successional stock, and the old stock of Roses richly top-dressed.

GREENHOUSE AND CONSERVATORY.

At no period of the year, perhaps, is caution in the use of fire heat more needed than in the month of March. March winds are proverbial, and March suns are at times intensely bright. Now, as these winds are by no means to be desired in hothouses, the very best plan is to keep fire heat to the lowest possible pitch all the morning, and when forcing is going on to have a lively fire for a couple of hours in the afternoon—say from three o'clock until five. By these means the necessity of giving much air will be obviated, and the climate within maintained in a most wholesome state as regards moisture, &c. Frequent attention is necessary at this period, both to the giving of air and also to the taking it away gradually. A considerable reduction should soon be made in forcing-houses, and the whole should be taken entirely away as soon as it is considered safe. Canvas shading will be in great requisition also. Conservatory plants to be retarded, Camellias making growth. Pines in a delicate state at the root, whether from disrooting or otherwise, and even the late Vines swelling their buds, will be benefited by a little shade during bright sunshine. In the conservatory, shading will now be of the utmost importance. Camellias growing should be so placed as to receive more shade as well as more atmospheric moisture than the general inmates of this house. They are, in fact, far better in a little close house by themselves, which should be kept up to 70° by day and 60° by night, receiving much the same treatment as Orchids at this period. Large specimens of Fuchsias should now receive liberal shifts; in fact, with well-regulated potting, and thorough drainage, they should be placed in their final pots or tubs at once. Now is a good time to sow imported or home-saved seeds of tropical plants. Half fill the pots with drainage; use peat, loam, and silver sand in equal parts; water the soil thoroughly but slowly with a fine-rosed pot, and cover the surface with a good coat of sphagnum. They may be placed on a warm shelf in the shaded part of the greenhouse. Some of the growing Ericas may be shifted now; use abundance of drainage and sandy heath soil full of fibres, thrust it in lumps round the ball, now and then forcing down pieces of stone or lumps of charcoal, and finally coat over the surface with some of the finer portions of the soil, which should have a liberal amount of sand. The ball must be moderately moist before shifting, for if thoroughly dry no after-watering can bring it right. Pot Cape or other bulbs as soon as the foliage is becoming strong, use chiefly loam, leaf soil, and silver sand. Dress Pelargoniums, and stake them out; slip off all inferior or ill-placed shoots, and make cuttings of them, they will flower well during the autumn. Lisianthus Russellianus should now have a liberal shift, with much drainage, and should be placed in pans of water in a Cucumber-frame, or other situation where there is a moist heat. Attend well to watering. Be shy, however, in watering newly-shifted plants. Do not water these heavily, give them a little and frequently through a rosed watering-pot until they become well rooted.

STOVE.

Growing Orchids will now require shading for a couple of hours during bright sunshine, for fear of too copious a perspiration; also in order to retard Dendrobiums, &c., in blossom. The latter, however, will do extremely well in a dry, warm parlour, or drawing-room, only they will require a good watering at the root occasionally. A very moderate amount of atmospheric moisture will suffice for these plants when in flower. The growing specimens must at this period have a considerable increase in this respect.

PITS AND FRAMES.

Much is now required here. Put in cuttings of everything that is likely to be wanted for spring planting. A mild frame heat is the most suitable for striking in. Bell-glasses are not required at this season, but shade slightly in the middle of the day. Pot-off struck cuttings as fast as room can be made by removing the more hardy kinds to colder situations, to harden off for the first planting. Pot-off Ten-week Stocks, and

other hardy annuals as soon as they are ready, and continue to sow seeds of all kinds of annuals that are most wanted, the more hardy kinds in beds or borders under hand-glasses.—W. Keane.

DOINGS OF THE LAST WEEK.

KITCHEN GARDEN.

For general details see last week. In addition, our chief work out of doors was Potato planting in the driest days. Planted the earth-pit, which, prepared as previously described, was in excellent condition, and the Potatoes were also in a good state for planting, being sprung about 2 inches, and had plenty of leaf mould about their roots, as the sets, mostly whole, had been set on shallow wooden boxes with leaf mould about them. As the open ground was not in first-rate order for Potatoes, except where it was well aired and dry, as at the foot of walls, we spread a little light dry soil and ashes and a little lime over the sets.

Peas.—Planted a row of Dillistone's Early and a kind with a local name, but almost if not quite identical, near the front of our two orchard-houses, the Peas turned out from semicircular drain-tiles, and placed about a yard from the front of the house. These are growing as if they had never been removed. In one house we had to take up a row of Lettuce, nearly half grown, in order to make room for the Peas, and planted the Lettuces with balls out of doors. There is a row of good-sized Lettuces behind the Peas, another row in front of them, and then a row of Parsley, that has done good service this winter. The Lettuces will soon be out of the way of the Peas, and by the time the latter need more room the Parsley will be of little value, as the plants out of doors will be growing freely by that time. Nothing will be done with these Peas but running a line along the back of the row, or some low twiggy sticks, to prevent the Peas leaning inwards to the house, the object being to encourage them to grow and cover the ground to the front of the house, the wooden ventilator being only a few inches above the ground level. We have had fine early gatherings with little trouble by this mode, the flowers and the pods standing well above the foliage and recumbent stems. We think it may be useful to some to say, that after trying a number of sorts for this purpose we have found none so good as Dillistone's Early, which, thus protected by a roof of glass, pods freely, whilst other early sorts, even Sangster's No. 1, podded but indifferently, though in general it far exceeds Dillistone's in produce out of doors, but is usually three or four days later. We have also placed in one house a row of Tom Thumb in pots close to the back wall. These Peas generally do well; but when of the same age as Dillistone's they will not be so early. Their dwarfness is a great recommendation for such positions, and for growing in frames or pits. They stand a moderate heat well, and succeed admirably in well-aired soil with the protection of sashes, the air removed early in the afternoon. We prefer them in pots at the back of an orchard-house or late Peach-house to planting them out near the trees, as, to make them succeed well, the ground would require to be more deeply stirred than we would like for the trees, and if planted on shallow-stirred soil they are subject to fly and mildew. They are also rather impatient of the syringing with different waters which the trees may require after the fruit is fairly set, and when in pots they may be lifted out of the way until the syringing is over.

The weather has been cold enough, and the ground has been too wet and unkind yet for turning out other Peas in tiles and turf, protecting and staking as we go on; but these are being hardened off to be ready as soon as the ground shall be in better condition. This plan, though involving a little more labour now, saves much seed, as well as looking after slugs and mice in winter.

In one of the driest days of last week sowed a piece of Peas and Broad Beans, the Peas fully 5 feet apart from row to row, and the garden Beans between them, the Peas being moderate growers. Taught by pheasants and partridges last year, we ran some hooped wood on each side of the piece sown, with a row of similar hoops in the middle, and then strained a piece of cord netting all over, fixed the net all round, and as yet the depredators have obtained no entrance.

We lately alluded to a first-rate, small-meshed, Pea-guard. Having used some two-inch-mesh galvanised wire netting, as advertised in the Journal, for keeping out rabbits, &c., and a little of it being left, we mean to bend its two-feet width into a semicircular shape, and fix it at each side with pins over a row of Peas, and we feel confident that, though the mesh will not keep out small birds, it will prevent such wholesale pilferers as pheasants attacking the Peas. The meshes will let the head and neck of the pheasant in, and there will be no danger of the bird being hanged, but the shoulders will prevent its reaching the Peas. We would, however, prefer the Pea-guards alluded to.

FRUIT DEPARTMENT.

Proceeded with pruning and nailing in the most favourable days, and especially when there was any sun, as it was easy to vary the position. We have not yet done with the Peaches and Apricots. The latter are freely swelling their flower-buds, but none are open yet, and we wish to keep them back, as March is yet young, but we have a lot of Laurel branches ready to place against them if we should have a severe night. Had we a cloth we would cover at present on every sunny day, and uncover in all weather not very frosty, until the blossom-buds began to open. The great advantage of a cloth for Apricots is that the blossom can be kept dry in cold sleety weather. The blossom if dry will stand a considerable degree of frost. Even a rather close net will do good, as the rain is caught in the net without freely reaching the wall. Laurel twigs used rather thinly make a fair protection when litter is not to be had.

Orchard-houses.—Had these cleaned out, as alluded to the other week, removing the litter that had been used for covering the pots, and taking off about half an inch of the dry surface soil, chiefly as a precautionary measure; slightly broke the surface with the points of a steel fork, gave a dressing all over of decayed Mushroom-bed manure that had been long enough exposed to kill every particle of spawn, and to make sure, as well as to help to enrich, mixed with it a bushel of soot and a bushel of quicklime, the latter settling any worms that might be present; patted this down, and then covered with a slight casing of fresh loam, the pots being also fresh surfaced to make all look well. Here we are reminded of a few matters we could not enter into last week.

1st, With regard to the firmness or looseness of soil about the roots of fruit trees in general and of Peach trees in particular. Could we always have our way we would prefer, after the trees had grown enough to be and continue to be fruitful, that the soil about the roots should be firm: hence, but for the necessity of watering and keeping the soil moist enough, we would not break even the surface often; but for such purposes breaking the surface is necessary, and then the manuring material being put on the surface, the water passes through it to the roots, which are thus encouraged to turn their mouths nearer to the atmosphere. Just as with propriety we make the soil firm in the pots for fruit trees thus grown, so on the same principle it holds that trees planted out should have their roots equally firmly packed. Why, even with a Cabbage plant, if we wish it to grow very fast we keep loosening and airing the soil about it, and giving it as much moisture, &c., as it can take in; but if we wished it to bloom and produce seed as soon as possible, we would beat the soil closely and firmly about the roots.

2nd, It is very mortifying, but yet it is very necessary, that gardeners who attempt to write for the pleasure and the profit of others should be obliged too often to say, "Do not always do as I do, but do as I tell you;" and consistently enough too, as circumstances may often be too strong for permitting the development of the intelligence gained in the school of experience. Thus, with a want of consistency, we have been telling of planting Potatoes at the foot of walls; lately of covering a bed of Endive in front of such a wall; now of planting out Peas, and of Lettuces in an orchard-house; and in addition all the fruit-tree borders will most likely be cropped. Now all this is done by hundreds of gardeners who would rather do otherwise if they could—and why? because they never have too much from the ground, crop as they may, and these borders in front of walls are so well protected. It has often seemed to us a strange anomaly, that a gentleman who lays no great store on his land, and lets it at 25*s.* or 30*s.* per acre, though such land generally carries no more than one crop in the season, should expect such wonders in the way of produce, and so many crops in a season from an acre or two of land which is called the garden. We would not advocate large walled gardens if much of the commoner produce were cultivated in fields, for then fruit-tree borders might be left to the fruit trees, and if that even could not be, then it would be better in every way that these borders should be cropped, and the roots of the trees confined to a space 5 or 6 feet from the wall where surface-dressings could be given, and the soil kept

firm without repeated diggings and trenchings for vegetable crops.

3rd, As frequently stated, we have no objection to fruit trees in pots. It is an interesting mode for having good, compact, fruitful bushes or pyramids of Cherries, Plums, and even Peaches; but what we chiefly object to is the trouble and labour they occasion in watering. Our houses are lean-to's, with trees against the back wall planted out in the usual way, and trees in pots in the front of the house. Now, as a mere matter of economy in labour, we would prefer, as there are trees on the back wall, that there should be trees planted not far from the front, and trained on a rounded trellis high enough to permit the sun to reach the bottom of the back wall. Then, too, we could have the floor of the house at liberty in winter and spring. True, we could gain that object to a great extent now, by taking out the hardier trees in pots, and packing the pots in litter out of doors all the winter, or even placing them closely together at one end of the house; but either of these operations requires time and labour to move and move again the plants; and from a scarcity of that time the pots often remain in their places all the winter, being merely lifted up in the autumn to break off all roots that may have extended themselves beyond the pots. Now, judging from the way large Lettuces stood in these orchard-houses with just a sprinkling of hay over them in the most severe frosts, and how dry and comfortable such salading, Cauliflowers laid in in moss or litter, and hundreds or thousands of Strawberry-pots could stand secure in the wettest and coldest weather on the floor of such a house, additional reasons will be apparent for having the trees planted out instead of in pots; still, for all amateurs who have little room, who wish much variety in it, and who will feel a pleasure in attending to the wants of their favourite trees, the culture of fruit trees in pots will always be attended with great zest and pleasure. After a fair trial we have no fault to find with the system but the additional labour in watering, the greater attention required to avoid dryness, and either the extra labour or the extra room taken up in winter, when the other plan of planting out would leave the floor free for several purposes, such as forwarding many vegetables, as Peas, Potatoes, Kidney Beans, &c., in tiles, turves, and pots, before planting out in fine weather.

Vine-borders.—The cold wet weather having cooled and wetted the slight covering of litter and leaves, we put on about 8 or 10 inches of hot tree leaves next the ground, placing the colder on the surface, but collecting most of the litter previously employed into a ridge 2 feet wide back and front, and about a foot or 15 inches higher than the bed in the middle. On these ridges flat rails were placed longitudinally, on which old sashes rested back and front. The mild heat beneath the sashes will be taken advantage of for potting off lots of bedding Pelargoniums, or rather for fixing them singly in pieces of turf 3 inches square and 2 inches deep, the hole cut out being filled with light rich soil.

ORNAMENTAL DEPARTMENT.

Rolled the lawn, switched walks, turned over ridged-up beds and borders, potted plants, made cuttings, hardened off cuttings, took flowering plants to conservatory, and in such cold winds gave but little air, and as little firing as was necessary to keep plants healthy. A little air constantly or early given is better than open lights in such biting north winds.—R. F.

COVENT GARDEN MARKET.—March 13.

Supply, demand, and quotations remain unaltered.

TRADE CATALOGUES RECEIVED.

William Paul, Paul's Nurseries, Waltham Cross, London, N.—*Catalogue of New Roses, Beaton's Hybrid and other Geraniums, Hollyhocks, &c.* Also, *Plate of Village Maid Pelargonium*, a beautiful Nosegay variety.

John Bruce & Co., 52, King Street, Hamilton, Canada West. *Descriptive Catalogue of Seeds for the Farm, the Kitchen Garden, and the Flower Garden.*

TO CORRESPONDENTS.

*** We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed *solely* to *The Editors of the Journal of Horticulture, &c., 171, Fleet Street, London, E.C.*

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

N.B.—Many questions must remain unanswered until next week.

Letters not Prepaid.—We have so many of these that we are obliged to decline receiving them; so the writers of them will understand the reason of their being unanswered.

Books (*A Four-years Reader*).—It is published by Messrs. Houlston and Wright, Paternoster Row, London. (*Brown*).—You can have "Out-door Gardening" free by post from our office if you enclose twenty postage stamps with your address.

Extent of Piping Required (*C. W.*).—You would require for a span-roofed iron conservatory, one end glass, 25 feet by 15, height from ground to apex of roof 15 feet, and the roof curvilinear, at least two four-inch pipes all round the house, or three on each of the sides.

Renovating Old Vines (*A Subscriber for Many Years*).—What you propose doing is good, but you should lose no time in performing the lime-washing, and in thoroughly cleaning the house. To the lime you may add one-third its bulk of flowers of sulphur before forming the wash. This may help to prevent attacks of red spider. We would advise you to remove the old soil to the depth named, or even deeper if it can be done without injuring the roots, and then to point-in the crushed bones and lime rubbish, and cover the border with 6 inches of fresh soil. The best is turf, 2 or 3 inches thick, chopped with a spade in its fresh state, mixed with one-fourth lime rubbish, and one-sixth crushed bones. The turf should be from a good loamy soil. If you could cover the border with 18 inches or 2 feet of hot stable manure, it would tend to attract the roots upwards and make them active in the new material. It may be removed in May.

Hotbed Making (*Inquirer*).—Mark out a space a foot wider than the frame all round, place a layer of long litter on the bottom, mix the hops and stable manure together and put them in layers, shaking out and beating well down as the work proceeds, until you have made a bed a yard high. Put on the frame, close the lights, and in a week the bed will have heated. Take off the lights, level the bed, and if it is very hot put on the lights, but leave them open a little at the back. Thrust a stick about a yard long into the centre of the bed from the outside under the frame, and by drawing this out you will on feeling it ascertain when to cover the dung with 3 inches of sand. The time to do so is as soon as the stick can be held tightly in the hand. The bed should be levelled before putting in the sand, which will keep down the rankness of the bed. The temperature within the frame should range from 65° to 75°, and in this the cuttings will strike in ten days or a fortnight. If you have sawdust you may put in 6 inches of it, and in that plunge the pots of cuttings, taking care that the heat is not greater than the hand can bear when thrust into the sawdust and kept there a few minutes. If so hot that the hand has to be withdrawn the pots or pans must not be plunged, but should be set on the material. Shade from bright sun, and keep moist but not very wet.

Lilium auratum (*E. M. B.*).—You will see the information you ask for in an answer to a correspondent last week. To write on Lilies generally would occupy pages of our Journal, which we cannot spare just now.

Rain Water Becoming Hard (*G. B.*).—If it does become hard, but which is improbable, it must be from the lime, or salts of lime, which it dissolves from the bricks and cement. Exclusion of air from the tank would not cause hardness.

Boiler Heated by Gas (*P. K.*).—A cast-iron boiler will be durable. The sulphurous acid in the gas, if not much purer than it usually is, would corrode the bottom of the boiler outside as you describe.

Pea Protectors.—"Your correspondent, 'R. F.,' in 'Doings of the Last Week,' lately asked a question about Pea protectors. I have tried them and found them answer as an effectual protection from sparrows, which are sure to attack Peas as soon as they appear above ground. The protectors are made of galvanised wire, twenty meshes to the foot, and are 8 inches wide, and 5 inches high. Enough protectors are required for one sowing, and as soon as the plants have grown an inch or two high the protectors may be moved to the next sowing, which will be coming through the ground. As soon as the protectors are moved away from the Peas these ought to be staked, as the birds will then not be so apt to attack them.—J. Douglas."

Ants in a Peach-house (*C. B.*).—They are driven away by sprinkling a little guano over their haunts, or by watering those haunts with ammoniacal liquor from the gasworks. Either of the applications must be repeated daily until the ants have departed.

Tricoloured Pelargonium Leaves (*E. S.*).—Nos. 5 and 3 are of unusual colours, but 5 is by much the most richly and peculiarly coloured—one-half dark green ground, the other half yellow ground, and each with the scarlet and other markings, the midrib exactly dividing the special colouring.

Deodorising Night Soil (*A Florists' Flower*).—No chemical mixture is needed. Cover it over with earth immediately; earth is the most effective of deodorisers. Sulphate of iron mixed with night soil, and used as a liquid manure, will not injure your Roses and Pansies. The other chemicals which you mention would kill or seriously injure plants.

Grafting Weeping Ash (*R. H. A.*).—The best time to graft stocks of the common Ash with scions of the Weeping Ash is when the buds of the stock begin to grow. Grafting may, however, be done when the sap is flowing freely, which will be the case by the end of April or early in May.

Marrow Peas for August or Beginning of September (*Idem*).—You should make a sowing of Ne Plus Ultra in the third week in May, or if your soil is heavy a week earlier. To make certain, when everything depends on the weather, you should sow Ne Plus Ultra in the second week in May, and in ten days make a sowing of Ne Plus Ultra and British Queen. The above are tall growers (6 to 7 feet) in good soil; if you wish for dwarfer sorts, then sow Veitch's Perfection, Yorkshire Hero, and Hairs' Dwarf Mammoth. The ground should be in good heart.

Pruning Old Vine (*J. W.*).—Your old Vine with shoots 6 or 7 feet long should be at once pruned. If the stem is very old, and one of the long shoots come from it at the bottom of the rafter, we would cut away the old stem to within a short distance of the point from which the shoot takes its rise, pare the stem smooth, and cover it with Thomson's styptic to stop the bleeding that must follow pruning at this season. We would leave the shoot at its full length, bending it down in front of the house to induce the eyes to break throughout its full length, and when these are a few inches long we would tie it to the wire, and the shoots right and left of it, stopping them one joint above the fruit, or if there were none at the sixth joint or leaf, a strong shoot from the upper part being retained as a leader. If there is no eligible shoot from the bottom, prune the long shoots to two eyes, and you will, if the wood has been well ripened, probably have fruit this season.

Yucca Drooping (*A Subscriber*).—The lower leaves of the plants droop from the exposure of the roots to the drying influence of the atmosphere. Water it, giving it a thorough soaking, and place it outside, the tub being protected from frost and the air by plunging, or by placing some material around it.

Beurré Claimgeau Pear (*S. S. S.*).—You can have it from any of the large nurserymen near London.

Angle of Vinery Roof (*G. P.*).—There is no better general angle for the roof of a house than 45°, which does well for early, late, and intermediate crops. When vineries have flat roofs, as in lofty houses, with upright glass in front, the upright glass compensates for the flatness of the roof, receiving, as the upright glass does, the rays of light almost perpendicularly in the early and late months of the year.

Vegetable Marrow Raising (*S. M.*).—It is too early to sow seeds of this plant in the open ground, affording them but a temporary protection of boards. Your best plan would be to ask some gardener to raise a few plants for you, or perhaps a neighbouring gardener would give you two. You may plant them in the bed; the boards nailed round the bed, and the oiled paper frames for covering the latter, would be useful. Plant about the middle of May. Two plants will be ample for the space you name. If you cannot procure plants you may sow the seed early in May, and cover with the oiled paper frames. You should afford them from 9 inches to a foot of good, rich, rather light soil. You could raise Cauliflower plants on the bed before it was wanted for the Vegetable Marrows.

Melon for Exhibition (*Clericus*).—Oulton Park Hybrid is one of the finest of the Scarlet-fleshed kinds, and Green Pine-Apple Gem of the Green-fleshed kinds.

Mulberry Unfruitful (*Idem*).—The cutting back or down of the tree would cause the production of strong unfruitful growth. We apprehend its vigour will now be spent; the shoots must be kept moderately thin, and the foreright and side shoots closely pinched at the third leaf. It will fruit in a year; if not, root-prune it.

Climbing Plants for Greenhouse with Vines (*Inquirer*).—The following will do well trained to fan, conical, or balloon-shaped trellises, which should be made of wire, and painted green. Lapageria rosea, Hibbertia dentata, Kennedya hoophylla floribunda, K. Marryattæ, and K. bimaculata variegata, Jasminum gracile variegatum, Rhynchospermum jasminoides, Pergularia odoratissima, Tropæolum azureum, brachyceras, and tricolorum, and Sollya linearis. They cannot have too light and airy a situation.

Indian Corn (*Idem*).—The best plan is to sow the seed in pots placed in the greenhouse, or, better, in a hotbed, from which, when the plants are a few inches high, they should be removed to the greenhouse. Afterwards harden off, and plant out in the open ground in good soil and in a warm situation early in June. You may grow it in the greenhouse, using nine-inch pots; but, unless well syringed, you will have a plague of red spider, and under no circumstances is it worth the trouble. Do not be misled by Mr. Hullett.

Gentiana acaulis and Alpine Rose Seed Sowing (*Novice*).—The seed of both the Gentiana and Rock Rose, or Cistus, may be sown now in pans three parts filled with crocks, and then to the rim with a compost of turfy loam and sandy peat in equal parts, adding a third of silver sand. The compost should be chopped fine and sifted, the roughest parts being placed over the crocks or drainage, and the finely-sifted soil on the top. Make the surface smooth, scatter the seeds over it, and cover very lightly with fine soil. Give a gentle watering through a fine rose, and place the pans in a cold frame, which should be kept close until the plants appear, when air may be freely admitted; expose fully in a few days. The soil should be kept moist, but not saturated with water.

Name of Fruit (*C. B., Bawtry*).—*Pear*, Bergamotte Esperen.

Names of Plants (*A. N.*).—We cannot name plants from the mere tips of shoots beaten flat by the post-office punches. (*F. G.*).—The two leaves are of the Loquat (Eriobotrya japonica). Trained against a south wall it will endure our winters. See our last volume, page 226, for directions as to culture, &c. (*W. F. R.*).—Arabis verna, or Spring Wall Cress.

METEOROLOGICAL OBSERVATIONS in the Suburbs of London for the Week ending March 12th.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

BRAHMA'S USURPATION OF THE DORKING'S THRONE.

Sir,—I am a Dorking cock of the purest blood and proudest lineage. My ancestors have been settled in Surrey since, we believe, shortly after the Deluge; we never have quite forgiven that upstart, William the Norman, for first intruding himself, and then intruding French eggs into England. Nature endowed us with an extra claw to each foot, to mark that we were superior to every other fowl. When Mrs. Game calls upon my wife, she does, indeed, treat her as an equal, and is mighty civil to her; but then Mrs. Game saw good society until the last few years, when her husband, being deserted by noble lords, took to low public-houses. Still, though we are sorry, we always say, "Game is a gentleman by birth," though even he has never been admitted, as we always have been, to the tables of the great, where every one expects to meet us, and is sorely disappointed if any other fowl is present in our stead.

Well, sir, knowing my place, as I am thankful to say I do, judge my indignation when I learnt that Brahmas are to have a prize of £6 at the Bury St. Edmund's Show, and Dorkings, and all other varieties only £5. I have crowed myself hoarse, sir, about it. I have been so angry, and become so red in the gills, that my wife, fearing apoplexy, said to me, "My dear Dorking, go to Mrs. Goose, and beg her to give you one of her quills, she is very good-natured, and write off to 'our Journal' about it, that will ease your mind." So, sir, here I am, pen in foot, and my indignation is so great that I fear my scratches will sorely puzzle your printer's devil.

What can that Committee mean by putting these Brahmas

above us? And now I must let you into a little family history of which we have all along been rather ashamed, and so have kept it close. The truth is, these Brahmas are related to us, but not in a respectable way. A sister of my great-great-great-grandmother, a giddy young thing of strange tastes, fell in love with a young Cochin cockerel. Whatever she could see in his coarse yellow legs we could not understand. The fellow had not even a tail, our pride and glory, and besides he had never learnt to crow properly; we thought he was asthmatic from sleeping in a damp roost. Well, to hush up the affair, it was so disgraceful, we sent off the couple to America, when judge our surprise, the impudent hussy sent her brats to England, and pretended they were a new and distinct race of fowls, and she actually took in a number of good-natured, or rather, weak people, and we laughed at the boasted discernment of man.

Now, to think of these illegitimate children setting themselves, aye being set up, above us, is too bad. Even a great advocate of Brahmas in your last week's issue (February 28th)—we always read the Journal—said, "As table fowls they are not equal to Dorkings." As to their eggs—well, if you dip a silver spoon in a Brahma's egg, and another in an egg of one of my dear daughters, you will find next morning the spoon placed in the egg of the former is far more discoloured than the one placed in the egg of the latter, the reason being that the coarseness derived from the Cochin is inherited to a degree by the Brahma, and there being much more sulphur in the egg the spoon is more discoloured. This I was told by a scientific gentleman.

But, sir, we fowls do not come into the world merely to lay eggs, we supply food to man. Look at our beautiful broad, deep breasts as they lie bare and white on dinner-tables, and look at our short legs.

But, Sir, this setting up Brahmas above Dorkings won't do. I can thrash Mr. B. alive, and beat him when dead, man being the judge. My wife will lay her eggs against Mrs. B.'s for quality, and show her bust and legs against her before any jury of housekeepers in England. Then, as to the much-vaunted laying of Miss B., there is a pretty little cousin of ours, of the good old English breed, who used to be called "Everlasting Layers," now absurdly called Hamburghs. Well, Miss Hamburgh, I know, lays more eggs even in winter than Miss Brahma, and a great deal better ones, too; and then, is not Miss Hamburgh a pretty dear? Yours, with all respect—OLD DORKING COCK, *Dorking Castle, Surrey.*

[Every one will sympathise with our old English bird, and *when* they read it all the tenants of the Surrey poultry-yards will flap their wings applausively of his letter.

We quite agree with Cowley, that

"'Tis greater to restore, than to usurp a crown."

So we will do our best to replace the diadem of poultrydom on old Dorking's head. With that intent we publish the following from the pen of a good authority:—

"Brahma Pootras are admittedly good winter-layers (if pullets of the previous year, as no old hens of any breed ever lay early), and that, of course, is when eggs are most valuable; nor does cold weather stop their laying, unless extraordinarily severe; that, too, is a very good feature. The eggs, also, are without a doubt, very excellent in quality, and from being hard and thick-shelled, they keep good longer by far than most eggs—such as Spanish, for instance.

"Against these merits it must be noted, Brahma Pootras are unquestionably 'very great eaters,' and the eggs, for the size of the fowls, are unusually small. The flesh of the very young Brahmas is good, but if kept to be above half grown, they are very coarse-fleshed, and Cochin-like, with yellow "hides" (for you can hardly call it skin), not suitable at all for boiling.

"Whatever may be stated to the contrary, Brahmas are 'leggy'—that is, the thighs are mostly coarse and large, a Dorking for the table being quite a different sort of dish. A cross between Game and Dorking (only a first cross), is one of the most hardy and best table fowls I know."]

INQUIRY.

I BEG to inform your inquirer that I have had dealings with Mr. Brooksbank, No. 4, Back Rolleston Street, Manchester, and believe him to be an honest, though probably a poor man. He has purchased Spanish fowls from me, and of the "crack strains" of Rake, Rodbard, and Teebay, and he has paid me honourably, sending the post-office order with the order for the birds. I feel in justice to Mr. Brooksbank bound to send this communication for insertion in your next issue, as such an inquiry is calculated to do a man, especially a poor man, much harm. I have frequently seen his name in the prize lists of THE COTTAGE GARDENER, which one would have naturally thought would have been sufficient to have kept such an inquiry from being made public. Further, I have seen upon referring to Mr. Brooksbank's advertisement, in the Journal of February 28th, that he gives the names of the shows where he has taken prizes and commendations, and think it would have been more prudent for your correspondent to have referred to those shows previous to maligning the character of such a one.—WILLIAM H. WHEELER, *The Cottage, Carlton, near Nottingham.*

BREEDING DARK BRAHMA POOTRAS.

(*Concluded from page* 186.)

I HAVE shown in two former papers that it is no easy matter to obtain these fowls of a high type, even as regards the more general points of form, size, and comb; but there yet remains the greatest difficulty of all, that of breeding them true to colour. That it is a difficulty many a beginner knows only too well; and, in fact, I know of no breed in which so much careful study is requisite to success.

The difficulty is, that whilst none of the poultry books recognise more than one colour in Dark Brahmas, described as "dull white, nearly covered with minute pencilling of a black or dark grey colour," there are many different strains as distinct in their prevailing tints as can possibly be, and some also varying in the character of the pencilling itself. This is no new fact to old breeders, but it has never been noticed in any work on poultry, and should be clearly explained for the help of beginners. Let any such examine at a large show a pen of Mr. Boyle's birds, and then compare with them any pair of hens shown by Mr. Lacy, and he will not fail to notice the distinction I am speaking of. The two pens will be types of two as distinct "schools" of colour as can well be imagined. I will not here go into minute differences in the form of the pencilling, but will only remark, that whilst the aim of Mr. Boyle is evidently to obtain as clear a ground colour as he possibly can, in which he has to a great extent succeeded, many of his birds being quite free from any shade of brown, Mr. Lacy, as is well known, considers brown the correct ground colour of a Brahma, and avowedly seeks to produce it, with the salmon-coloured breasts for which his pens are distinguished.

I have taken these two strains simply as being the two widest apart that I know of, and abstain most carefully from giving any judgment as to which is the correct standard. I have my own decided notions on this head, but such matters belong strictly to private opinion, and my object just now is only to point out the difference. Such differences and peculiarities in other well-known strains, equally characteristic, but, perhaps, less striking to a mere casual eye, will at once occur to the experienced reader: but I will only mark one, that whilst some strains are noted (Mr. Hinton's, for example), for the distinctness of the pencilling, every feather being marked with bars of black as sharply defined as in a Pencilled Hamburgh; in others the feather is so heavily covered with the black marking, that until closely observed the effect of the whole is like a uniform dark ground colour. These are not accidental differences; each character and colour of pencilling has its admirers, has been produced and perpetuated by careful breeding, and is in most cases a marked and known characteristic of the strain to which it belongs.

Now, the point I wish to call attention to is this, that whilst the hens thus vary, there is no apparent difference in the cocks, at least in most cases, and except to a very practised eye; and if in purchasing stock the beginner simply buys the best cock he can procure, and mates him with the hens which most strike his fancy, the chances are that the produce will greatly disappoint him. I do not mean to say that if both be really good birds there will not in the worst case be some good chickens; but I mean that there will be no certainty whatever what colour the chickens may be. For instance, to take the two strains just noted, I knew a case where a splendid cockerel of Mr. Boyle's was mated with two very good hens of Mr. Lacy's strain. The result was just what I should have expected, both colours were spoilt except in a very few cases, and the pullets were for the most part of the clear grey colour derived from one strain disfigured by brown patches imported from the other.

It will be understood again that I am making no invidious

comparisons. I admit to the fullest the right of every one to his own opinion, and desire simply to point out and lay stress upon the fact, that whatever be the colour preferred, it will be much injured if indiscriminately crossed with a strain from which it greatly varies.

In commencing the breeding of Brahmas, therefore, it is necessary first to determine the kind and colour of pencilling which shall be adopted, and then to see that all cocks purchased are of strains which come pretty near it. For instance, if a cock be seen and admired, the hens shown from the same yard should also be examined, and unless they also approach tolerably near to those already in the yard the male bird should be rejected. I am supposing all along that exhibition excellence, and, consequently, uniformity in marking, are desired. Those who keep fowls for only their flesh and eggs need no such directions; but that they will not be useless to exhibitors is proved by the numerous unsightly pens I see at every show, containing birds of all kinds of irregular and mottled colour, caused by this ignorant and indiscriminate crossing of different strains.

Whatever be the colour preferred, it is of very great importance that the breast be well and darkly covered with pencilling. No pullets not thus marked can be called really good. To obtain such the breeding cock should be chosen with breast, thighs, and under parts as nearly as possible jet black, taking especial care that the fluff about his thighs do not show much white. The latter is very apt to breed what I consider most unsightly pullets, with a white streak down the centre of each feather, as in the back of a Silver-Grey Dorking. A spangled-breasted cock is by no means bad for breeding, however, and for exhibition far preferable; but it is certainly essential to good pullets that the thighs and legs be as dark as possible.

With respect to the character of the pencilling, my own preference is for the well-defined Hamburgh-like marking, and to obtain it in perfection the cock must be selected with the greatest care. The signs of the needful quality in him are in the sharp edges of the black stripes on his hackle and saddle-feathers, especially the latter. In many birds the saddle-feathers nearest the tail are very "cloudy," and such will never breed well and sharply-pencilled pullets, for which it is highly necessary to select a cock in whose saddle-feathers right up to the tail the central black stripe is clear and dense with a well-defined edge. The neck-hackle should have plenty of black in it about the shoulders, or the pullets will be too light in the plumage. For the more minute and heavier pencilling less care in the selection of the cock will be necessary, provided, as before remarked, the yard which bred him correspond in character with the colour desired, and his general plumage, form, and size be satisfactory.

I should myself prefer mating a two or even three-year-old cock with three pullets. Many prefer a cockerel with two-year-old hens, and the chickens are certainly larger at first; but I believe that those hatched from pullets have usually most constitution, and eventually make the largest birds. This point, however, is comparatively immaterial, but the number of hens or pullets to one cock should never exceed three in any of the very large breeds.

In these remarks I have endeavoured to serve all and offend none, leaving to each the free choice of that "school" of colour to which his fancy inclines. On a future occasion I will briefly mention the crosses usually found in Brahma fowls, and the means of their detection.—Nemo.

BREEDING GAME FOWLS.

(*Continued from page* 186.)

In crossing colours when the hens are of a stronger and harder colour than the cock, most of the cock chickens will be of the hen's colour, and most of the pullets of the cock's colour; for instance, in crossing Brown Red hens with a willow-legged Black-breasted Red cock, most of the cocks will be Brown Reds, and most of the pullets of the Partridge colour. This, however, is not a good cross.

The different colours of eyes should never be crossed or bred together, as this produces mongrel or mixed colours as soon as anything, even if the fowls are of the same colour in plumage, but with different-coloured eyes. Red eyes should be bred with red eyes, black eyes with black eyes, and yellow eyes with yellow eyes. Bay eyes and light brown eyes are the mixtures, and sometimes by bad crossing some birds have one eye red and the other eye yellow.

Game fowls are in their prime at two years old, cocks as a rule declining after four years old, and hens declining after five years. The cocks wear out faster than the hens, the fecundity of the latter notwithstanding. Many birds are, however, quite healthy and vigorous at much greater ages. I have known a Game hen breed good chickens at ten years old, and many valuable brood cocks have been bred from at eight and nine years old. Such old hens only lay about one clutch of eggs in May or June, and after laying about a dozen eggs cease laying altogether for the year, bringing up their own chickens well if put on their own eggs.

In choosing eggs for sitting, they should be examined or looked through by means of a bright candlelight, and such as are clear to look through, with the air-bladder plainly distinguishable at the large end of the egg, are fresh and good, while such as appear spotted and clouded are too stale.

Good stags and pullets will, of course, produce better chickens than any bad full-grown birds, but as a rule full-grown birds breed the best. In crossing and mixing colours in breeding, all the colours incline to breed back to the darker original colours (the Black-breasted Reds and Brown Reds), Duckwings always breeding back to the Black-breasted Reds, Dark Greys and Dark Birchens to the Brown Reds, and the lighter colours, such as Piles, to the Ginger Reds. The Brown Red colour prevails the most in crossing, and the Black-breasted Red is the next in general.

Eggs laid in March will, as a rule, produce the most cock chickens, especially if first strings or clutches of eggs after moulting. Eggs laid in the warmer and softer months produce most pullets. Dark Greys and Brown Reds will throw most cock chickens and the fewest pullets, and the willow-legged Black-breasted Reds, and the yellow or daw-eyed sorts throw most pullets and fewest cocks in proportion. The other sorts are intermediate between these in this respect. Black-eyed and red-eyed breeds produce most cock chickens. I have now been sufficiently prolix, I believe, on the subject of breeding.—Newmarket.

SUMMER POULTRY SHOWS.

Would it not be well if committees would take into consideration the extreme heat of the weather in the months of June, July, and August, and reduce the pens of large birds—such as Dorkings, Cochins, and Brahmas—to a cock and one hen instead of two hens? I think this would contribute greatly to the health and comfort of the birds, as I have seen them much distressed at that season of the year.—An Exhibitor.

POULTRY PRODUCE.

I again submit my poultry account of the past year for your inspection. My poultry yard for the first six months was made up of four Dorking and two Brahma hens, and during the remainder of the year of four Dorkings only; the produce has been as follows:—

January	65
February	68
March	77
April	62
May	73
June	58
July	64
August	63
September	23
October	2
November	18
December	41
Total	619

	£	s.	d.
Receipts	5	13	8
Expenses	4	5	1
Profit	1	8	7

Twenty five chickens were hatched, and twenty-one reared.

In this account I have only charged 1*d.* on each egg consumed by ourselves, that being I think about its real value.

I find feeding fowls when at roost during the cold winter months conducive to early egg-production. During December and January fowls, of course, go to roost very early, and however well fed during the day, by 8 or 9 o'clock in the evening their crops will be found quite empty. While the past severe weather lasted I adopted the following plan:—About 9 o'clock I mixed up about as much barleymeal as six hens and a cock would be likely to consume, together with a small quantity of

fat, when obtainable, and also leaves of winter greens thawed and chopped fine. This treatment put my birds in fine condition, causing them to commence laying as early as the 26th of January, and up to yestesday, the 24th of the present month (February), they have shown their gratitude by laying the very respectable number of eighty-nine eggs, or an average of three per day.

If a good egg supply is desired empty crops should not be tolerated, at the same time over-feeding must be avoided.

My fowls have only a 12-feet-square run, but are let into the garden during the morning for a short time at present; this privilege, however, must soon be stopped.—J. M. S.

THE THORNE ORNITHOLOGICAL SHOW.

This Society held their second annual Exhibition of Pigeons, Rabbits. Canaries, &c., in the Temperance Hall, Thorne, on the 5th inst. The specimens numbered from 160 to 200, and were of first-class character, attracting much attention. The *Rabbits* were particularly choice and of extraordinary dimensions; they would not have disgraced some of the first shows in the country. One Rabbit was sold for £5 15s. The largest and most successful exhibitor of *Pigeons* was Mr. H. Yardley; of Rabbits, Messrs. Hanson & Wagstaff, of Thorne; and of birds, the Rev. H. C. Russell, of Doncaster, who purposes giving a prize for Lizard Canaries at the next Exhibition. The Hall was tastefully decorated with evergreens, &c., by Mr. Charles Haycroft, one of the Honorary Secretaries, who with his coadjutor, Mr. H. Cawood, and the Committee, were most successful in the whole arrangements.

Mr. T. Addey, sen., of Epworth, exhibited a novel and very interesting observatory bee-hive, which, being composed chiefly of glass, displayed the comb, the honey, and the bees at work. The attendance was large, and the Exhibition must have been a success.

Carriers.—First, H. Yardley, Birmingham. Second, W. White, Snaith. Third, H. Grant, Thorne.

Croppers.—First, F. Key, Beverley. Second, H. Yardley. Third, T. C. & E. Newbitt, Epworth.

Tumblers.—First, C. Gravil, jun., Thorne. Second, H. Yardley. Third, F. Key. Commended, J. Wrigley, jun., Thorne.

Fantails.—First, A. Parry, Rochdale. Second, H. Yardley. Third, T. C. & E. Newbitt. Commended, C. Cussons, Hull.

Jacobins.—First, A. Middleton, Newport. Second, H. Yardley. Third, C. Gravil, jun.

Barbs.—First, Rev. W. J. Mellor, Colwick Rectory. Second, H. Yardley. Third, A. Dove, York. Highly Commended, F. Broemel, Ladywell, Kent.

Goldfinch.—First and Second, Rev. H. C. Russell. Third, C. Chappel, Thorne. Highly Commended, C. Purdy, Thorne; G. Richardson, Stainforth. Commended, H. Grant.

Linnet.—First, Rev. H. C Russell. Second, C. Outlaw, Thorne. Third, J. Wrigley, jun. Highly Commended, C. Temperton, Thorne; R. Gravil; H. Grant, Thorne.

Mule.—First, J. Haycroft, Thorne, Second, Miss Raywood, Thorne Third, C. Tomlinson, Thorne.

J. Richardson, Esq., officiated as Judge.

FUMIGATING BEES.

My difficulty is that in a well-populated hive a moderate amount of smoke does not reach or affect a very large proportion of the bees, by reason of their being clustered close together between the combs or partly within the cells. If more smoke be applied the bees nearest the entrance are killed by the overdose, and even then do not fall down so as to be cleared away, but hang to one another, requiring the application of a feather, which, after all, does not perfect the operation, many bees remaining among the combs and regaining consciousness, not in the best of tempers, during the process of cutting out combs, &c. After fumigating or sprinkling with peppermint water both lots of bees, I have never as yet found any difficulty in uniting.—C. C. Ellison.

[When, during our novitiate in bee-keeping, we resorted to fumigation we always used sufficient smoke to quiet all the bees, and in this way escaped the difficulty you speak of. Driving is, however, so easy, and fumigation at all times so unsatisfactory, that we would earnestly advise you to endeavour to master the former, and entirely discard the latter.]

BEE-KEEPING IN DEVON.—No. XXVII.

NON-RESISTANCE, OR "PEACE AT ANY PRICE!"

A valued apiarian correspondent writes me as follows:—"I have an instance of marauding bees plundering, without any opposition offered, the contents of a hive which I concluded was queenless; but on elevating the frames I found queen and bees in excellent order, and very much disposed to resent my interference. Can this be an instance of marauding bees having a signal similar to that of their unfortunate victims?" It is not a little singular that this letter came to hand the very day on which I had discovered a case of the same kind in my own apiary.

When the protracted frost broke up in January I lost no time in ascertaining how the stores of food held out in my various stocks, taking care in every doubtful case to make such additions as might insure my little *protégées* from present starvation. Among the stocks thus treated was one in which the bees appeared numerous, and which received a donation of a sealed honeycomb, in addition to a certain amount of liquid food. A more careful examination on the 12th of February revealing the unexpected fact that not only were the original and supplementary stores completely exhausted, but that the unfortunate colony was actually famishing, I at once surmised that it had been robbed, and concluded that most probably it was also queenless. A protracted series of examinations followed, during which every comb was more than once completely and most rigidly scrutinised, until it became pretty clear that no queen existed. The difficulty of "proving a negative" is, however, so well known, that I contented myself for the present with administering a moderate supply of food, and suspended proceedings until the next day.

The following morning discovered this queenless stock apparently in a state of the greatest activity, although no pollen was carried in. Evidently intelligence had reached the marauders that their former victims were once more "in funds," and the most active measures were again in progress for reducing them to their whilom state of utter destitution. A further strict examination proving that their recently acquired stores were rapidly disappearing without the slightest attempt being made to defend them, whilst no queen could be discovered, I at once reduced the number of their combs to four, and closed the hive. My next move was to examine the nearest stock which I found in a flourishing condition and possessing two combs of sealed brood. Having captured the queen of this colony, and placed her in a queen-cage with the view of protecting her from all risk, I removed two combs on each side, thus making room for the four remaining in the plundered hive, which I speedily lifted out, bees and all, and inserted in the vacancies thus caused. The few remaining bees having been rapidly brushed out on the top of the exposed frames, the whole received a sprinkling of syrup, the crown-board was replaced, and, the doubled hive having been shifted to a position midway between the two, the union was complete. During the remainder of the day the bees appeared very active and in a state of some little excitement, but not the slightest quarrel took place. The following morning I released the queen, saw that she was well received, and congratulated myself on the success of my manipulations.

As the day wore on, however, my suspicions became aroused. The doubled stock was far *too* active, but not a load of pollen was being carried in. An afternoon examination revealed the mystery—the bulk of the stores had already disappeared, whilst the remainder of the provisions was being rapidly carried off by a band of buccaneers; and all this without the slightest endeavour at defence on the part of the garrison, or any attempt being made to molest the queen, which traversed the brood-combs in peace and apparent security. Closing the hive once more, I set myself to watch the proceedings of the free-booters, whilst I deliberated what course would be the best to

pursue. The temperature was too low for fair work; but the suspicious activity of the plundered stock was emulated by one other in particular, which stood about a dozen yards off. Planting myself midway between these two, I soon made out a stream of bees rapidly passing and repassing between one and the other, so that no doubt could remain as to the identity of the actual culprits. Had any doubt been possible, it would, however, have been dispelled by an examination of the interior of the suspected hive, which, for an especial purpose, I deferred until evening approached, and which revealed the combs loaded almost to overflowing with the ill-gotten booty. Selecting one of the heaviest of these I brushed off all the bees, chuckling slightly to myself as I substituted this ponderous comb for one of the empty ones in the plundered hive; nor could I, even in the midst of my discomfiture, help feeling some little satisfaction at the idea of the retributive although tardy justice which I was executing in politely handing over to the marauders a perfectly empty comb, which they had themselves only recently been so assiduous in clearing out. My object in doing this so late in the day was to furnish the now nearly-destitute stock with a supply of food, which the buccaneers should not have time to remove before the approach of night compelled a cessation of their nefarious labours. As soon as darkness had fairly set in I shut up the victimised stock, and conveyed it to a dark cellar, there to remain until I could make arrangements for transporting it to such a distance as might place it entirely out of the reach of the buccaneers. Fearing lest these latter might transfer their unwelcome attentions to some of the neighbouring stocks, I left the outside case and roof in their place; and was not a little amused during the next and succeeding days to see a multitude of would-be plunderers investigating the empty case, in puzzled bewilderment as to what had become of its former easy-going inhabitants and their ill-defended stores.

The non-resisting hive having been transported about half a mile off, a distance which I have found sufficient so early in the season, quietude was restored in the apiary, and remained undisturbed until the 21st of February, when I ventured to administer a bottle of feed to the stock which stood nearest to the spot previously occupied by the removed colony. The usual degree of excitement supervened without creating any suspicion until the afternoon, when I was somewhat alarmed by observing the former freebooters and the inhabitants of the hive which stood next to them, and which I had more than suspected of taking a secondary part in their former nefarious proceedings, again manifesting a very equivocal degree of activity. Similar investigations to those above related, pointing irresistibly to the same conclusion—viz., that this third stock with a fertile queen and an abundant population was surrendering its stores without the slightest attempt at defence, it was in its turn shut up in the evening, and took its place the next day beside the other votaries of "peace at any price," where both stocks have since remained unmolested, and where they are both doing well.

With regard to the query propounded by my esteemed correspondent, I confess myself unable to come to any satisfactory conclusion, but must leave it to others to form their own opinions. Are these apian freebooters likewise freemasons? and are they in the possession of some mysterious password or signal which has served as an "open sesame" to the store-combs of three successive hives? Or may not the rightful guardians of these latter have joined the "Peace Society," and with all the fervid and undiscriminating zeal of new-made converts, carried their exemplification of the doctrine of non-resistance far beyond the practice even of that great advocate of peace, John Bright himself? However this may be, the probable result of a national adhesion to this doctrine may, I think, be reasonably inferred from the sad fate which must have inevitably befallen these apian votaries of "Peace at any price," had it not been averted by the timely intervention of—
A Devonshire Bee-keeper.

BLACK DRIVEN BEES.

These are so far all right, and were seen to take in pollen on February 17th, 20th, 24th, and 28th freely. They were driven on the 13th of September, 1866, and their previous history is stated in Vol. XI., page 399.

The lowest reading of the thermometer noted by me during the first week of January this year occurred on the 4th—namely, 7°; on the 14th of the same month the lowest temperature was reached, being 6°. My thermometer is fully exposed, with a north aspect, and is 4 feet from the ground in a walled garden, the elevation being about 340 feet above the sea.—J. G. C., *South Northamptonshire.*

FOUL BROOD—ASPECT OF APIARY.

The honey season is gradually approaching, and I have been taking a survey of my hives to see how they have stood the winter. A Stewarton hive attracted my attention by the appearance of robber bees, and on examining it I found the lower box full of empty comb, and some of it white with mould. The upper box is full of comb, partly filled with honey, and what I suppose is foul breed. I have excised this, cleansed the floor-board, and placed the box with the bees on it. It is quite possible I have not cut out all the foul brood. Will the taint remain in the hive in consequence? and have I done right in leaving the bees but the one box? I took from this hive a top box of pure honey last autumn, weight 13 lbs. I considered I had a flourishing colony. The bees which are left appear feeble.

The next colony, a Stewarton, also in the same bee-stand, is the most flourishing colony I have, excepting a Woodbury hive standing in a window at the top of the house on the north side. This was a May swarm of last year. It filled the hive and yielded me 5 lbs. of honey in a straw cap placed over the hole in the crown-board.

I shall be glad to know what you advise me to do as the spring advances. Shall I put on a large super, or distribute the bar-frames among other hives? I own that swarms come quite fast enough, and I rather aim at obtaining honey without multiplying swarms.

I consider a north aspect a far better one all the year round than a south or south-east one. Is this the opinion of your readers?—B. B.

[If you are right in believing that the combs contained foul brood the stocks should be at once destroyed, and the hive purified by scraping and a thorough washing with a saturated solution of chloride of lime, the remaining honey being applied to any purpose except feeding bees. We give this advice, believing that with foul brood, as with the cattle plague, the plan of "stamping out" on its first appearance is by far the best. As you aim at a good honey harvest rather than the multiplication of swarms, we should advise putting a large super on the Woodbury hive, substituting, however, an adapter for the crown-board. Experience has satisfied us that aspect is a point of very secondary importance in bee-keeping.]

FOUL BROOD (?).

I am desirous of communicating some particulars of my experience of foul brood. A few years since I had an apiary at Epworth, where I now reside, which consisted of fifty stocks all in one row, when this disease came amongst them. The first attacked was the tenth hive from the west end of the row, and fifteen stocks in succession were totally destroyed. More would doubtless have been infected had I not given them the strictest attention and used every exertion to stem the disease. I noticed from the first bees coming out of the hive and crawling on the ground to rise no more, appearing as though they had just made their escape from a treacle-pot, whilst others were going into the nearest hive, which led me to conclude that the disease was infectious. I therefore lost no time in removing all these stocks which showed symptoms of the disease, after which the rest went on well; so I lost sight of the pest for that season, which was a happy release. Although I have had to contend with it many different times since, I have never again experienced so fatal an attack. I had several stones of honey from the infected stocks, which I used after heating it, whilst I well washed all the utensils in hot water, and dried and aired them well before I used them again.

I attributed the origin of this fatal disease to having sent so many late swarms and condemned stocks of bees to the heather, where for the first few fine days the bees were able to collect honey; but after this there were two or three weeks of gloomy wet weather, so that the bees could not go abroad, which caused the hives to be full of brood, and before this was matured cold chilly weather set in, which compelled the bees to close up betwixt the combs, leaving numbers of the larvæ to perish in the combs. For these and other reasons I am persuaded that nineteen out of twenty such disasters are brought

on by the careless managers, who ought to see that all the stocks are brought up to the mark in September; and if feeding be required it should be done copiously at night, whilst in spring bees ought to be fed very sparingly. I may state from experience that feeding copiously in spring often causes the ruin of many good stocks, as it creates great excitement and confusion both inside and outside the hives, and, by developing so much more heat, induces the queen to fill the combs with brood, which, owing to sudden changes of weather, is often left uncovered, when vast numbers perish in the combs. I am convinced that dead brood will become noxious, and infectious too, if not removed in due time; and again, by feeding freely in the spring excitement and robbery often take place.—Thos. Addey, sen.

[The disease you describe is certainly not foul brood, which, as Dzierzon says, "does not affect adult bees, but only the brood;" but it appears to be nearly identical with what Mr. Woodbury has hypothetically denominated "dropsy." Its symptoms and the mode in which he successfully treated it were fully described in an article from his pen which appeared in page 534 of our ninth volume.]

DESERTION OF HIVES DURING SUMMER.

After considering the circumstances related by your correspondent "Nil Desperandum," No. 307, page 139, I am strongly of opinion that the desertion of his hives arose from their occupants being queenless. He probably subdivided them too much, and too often, which is never wise; but last season was particularly unpropitious for doing so. The continued wet weather caused many young queens to be lost during their flights, besides making bees generally very prone to rob each other's hives; and queenless lots do not, as a rule, defend their stores very long, but generally end by deserting to the enemy.—J. P. E.

Importation of Eggs.—The importation of eggs continues to increase annually. In 1864 they arrived to the number of 335,298,240; in 1865 to 364,013,040; and in 1866 to 438,878,880, which is approaching to one million and a quarter daily.

OUR LETTER BOX.

Fowls with Discharge from Nostrils and Eyes (*Lex*).—Your fowls are probably suffering from cold. If such be the case, stimulating food such as stale bread soaked in strong ale, is the best remedy. As they do not get worse, they are sure to get better, but will not entirely recover while we have the present cold winds. The ale you have given has probably kept them from becoming worse. If you have not used them, try Baily's pills for the roup. Calomel, soap, and pepper, and the feather, are all useless in this case. The last remedy is used only for gapes. The only external treatment for the fowls that weep from the eyes and nostrils is to wash the faces with cold water and vinegar.

Food for Turkeys (*Constant Subscriber*).—Your Turkeys, like many human beings, are suffering from damp weather and cold winds. Give them some bread and ale twice every day. The bread should be stale, and the ale strong. Your food should be barley, sometimes a few oats, and if it be varied by giving soft food every other day, the birds will do all the better. A capital meal for Turkeys is made of equal parts of oats and barley with a few beans, all ground and mixed together. This may be slaked with water or milk, and when suffering as your birds are, the addition of some onions chopped fine and mixed with it is often beneficial.

Houdans (*F. A. M.*).—In some of our back Numbers you will find pages devoted to the Houdans. The combs of the cock and hen are in front of the top-knot, rising in points at each end, with smaller points in the cock coming down to the nostrils. They are across the skull and not along it, as in many other breeds. The comb of the hen is much smaller than that of the cock, and the smaller points do not come down in front. They should all have five claws. They are heavier than they appear to be. The cock should, if a fine specimen, weigh between 7 lbs. and 8 lbs., and the hen 6 lbs.

Cochin-China Hen Staggering—Food for Poultry (*Buff*).—Are you sure your hen does not suffer from being egg-bound, or, at least, from laying her eggs with great difficulty? We ask the question because walking with her tail down is a great symptom of it. If that is the cause, the introduction of a wing-feather steeped in oil into the egg-passage will relieve her. We consider the ground oats we mentioned last week as the very best poultry food. A change is, however, sometimes necessary, and then whole barley is good feeding. We are not friendly to Indian corn as constant food, on account of its fattening properties, but once a-week it makes a good variety in the bill of fare. Continue the castor oil with the sick bird, and feed on bread, instead of meal, steeped in strong ale. Give a pill of camphor every evening. It should be the size of a pea. We are unable to state how much your birds should eat, as we do not know whether they can obtain anything beyond that which is given by hand.

Yard-floor for White Cochin-Chinas (*Wilmslow*).—We keep ours in a pen of about the same size as yours. The bottom of it is of gravel, covered some inches thick with road grit. This latter keeps dry, and soon dries up after rain; but we have given a fall to the pen which prevents any settlement of water on the surface. We find it helps to keep the plumage bright to turn them out on the grass at times, but whether we do or not their feathers are always bright.

Dorking Hens Pecking off the Cock's Feathers (*J. C. P.*).—As a rule, when fowls eat each other's feathers it is from a morbid appetite arising from a disordered state of body, or from the lack of something necessary to their health. It is strange that the victim of these attentions seems to like them, and will stand still not only while other birds eat his feathers but his flesh. Green food is generally a cure, and the best is to cut large heavy sods of growing grass with plenty of earth to them, and throw them into the pens. The bare spots should be freely rubbed with compound sulphur ointment; and it will be well to remove the cock for two or three days. This can be done even for a longer period without loss or detriment of any kind. We presume your birds are in confinement, as it is a habit seldom acquired when fowls are at liberty. They will eat the whole of the turf, grass and earth.

Aylesbury Drake (*A Constant Reader*).—We know of none to be sold near the Isle of Wight. Mrs. Seamons's direction is Hartwell, Aylesbury.

Exchanging Fowls (*T. M.*).—We do not know of any one requiring such an exchange, and the only mode of ascertaining is to advertise.

Fleas in Poultry-house.—The Feverfews, especially Pyrethrum roseum and carneum, produce flowers which dried, reduced to powder, and sprinkled about a place infested by fleas, are said to drive them away. There is no "Poultry Diary" now published One was published at Colchester, but has long since been abandoned. An interleaved almanac is quite sufficient for the purpose.

Eggs (*T. M.*).—The eggs were excellent and undistinguishable from others laid only a few days. If, therefore, they had been laid long since, as you intimate, we shall be much obliged by your stating the plan adopted for preserving them.

Game Fowls' Eggs (*A Cottage Gardener Reader*).—The hen hatching the eggs will not have the remotest influence over the courage of the chickens.
